Linux Driver-api Documentation

The kernel development community

Jul 14, 2020

CONTENTS

The kernel offers a wide variety of interfaces to support the development of device drivers. This document is an only somewhat organized collection of some of those interfaces —it will hopefully get better over time! The available subsections can be seen below.

Table of contents

CHAPTER

ONE

DRIVER MODEL

1.1 Driver Binding

Driver binding is the process of associating a device with a device driver that can control it. Bus drivers have typically handled this because there have been bus-specific structures to represent the devices and the drivers. With generic device and device driver structures, most of the binding can take place using common code.

1.1.1 Bus

The bus type structure contains a list of all devices that are on that bus type in the system. When device_register is called for a device, it is inserted into the end of this list. The bus object also contains a list of all drivers of that bus type. When driver_register is called for a driver, it is inserted at the end of this list. These are the two events which trigger driver binding.

1.1.2 device_register

When a new device is added, the bus' s list of drivers is iterated over to find one that supports it. In order to determine that, the device ID of the device must match one of the device IDs that the driver supports. The format and semantics for comparing IDs is bus-specific. Instead of trying to derive a complex state machine and matching algorithm, it is up to the bus driver to provide a callback to compare a device against the IDs of a driver. The bus returns 1 if a match was found; 0 otherwise.

int match(struct device * dev, struct device_driver * drv);

If a match is found, the device' s driver field is set to the driver and the driver' s probe callback is called. This gives the driver a chance to verify that it really does support the hardware, and that it' s in a working state.

1.1.3 Device Class

Upon the successful completion of probe, the device is registered with the class to which it belongs. Device drivers belong to one and only one class, and that is set in the driver' s devclass field. devclass_add_device is called to enumerate the device within the class and actually register it with the class, which happens with the class' s register_dev callback.

1.1.4 Driver

When a driver is attached to a device, the device is inserted into the driver' s list of devices.

1.1.5 sysfs

A symlink is created in the bus' s 'devices' directory that points to the device' s directory in the physical hierarchy.

A symlink is created in the driver' s 'devices' directory that points to the device' s directory in the physical hierarchy.

A directory for the device is created in the class' s directory. A symlink is created in that directory that points to the device' s physical location in the sysfs tree.

A symlink can be created (though this isn' t done yet) in the device' s physical directory to either its class directory, or the class' s top-level directory. One can also be created to point to its driver' s directory also.

1.1.6 driver_register

The process is almost identical for when a new driver is added. The bus' s list of devices is iterated over to find a match. Devices that already have a driver are skipped. All the devices are iterated over, to bind as many devices as possible to the driver.

1.1.7 Removal

When a device is removed, the reference count for it will eventually go to 0. When it does, the remove callback of the driver is called. It is removed from the driver' s list of devices and the reference count of the driver is decremented. All symlinks between the two are removed.

When a driver is removed, the list of devices that it supports is iterated over, and the driver' s remove callback is called for each one. The device is removed from that list and the symlinks removed.

1.2 Bus Types

1.2.1 Definition

See the kerneldoc for the struct bus_type.

int bus_register(struct bus_type * bus);

1.2.2 Declaration

Each bus type in the kernel (PCI, USB, etc) should declare one static object of this type. They must initialize the name field, and may optionally initialize the match callback:

```
struct bus_type pci_bus_type = {
       .name = "pci",
       .match        = pci_bus_match,
};
```

The structure should be exported to drivers in a header file:

extern struct bus_type pci_bus_type;

1.2.3 Registration

When a bus driver is initialized, it calls bus_register. This initializes the rest of the fields in the bus object and inserts it into a global list of bus types. Once the bus object is registered, the fields in it are usable by the bus driver.

1.2.4 Callbacks

1.2.5 match(): Attaching Drivers to Devices

The format of device ID structures and the semantics for comparing them are inherently bus-specific. Drivers typically declare an array of device IDs of devices they support that reside in a bus-specific driver structure.

The purpose of the match callback is to give the bus an opportunity to determine if a particular driver supports a particular device by comparing the device IDs the driver supports with the device ID of a particular device, without sacrificing bus-specific functionality or type-safety.

When a driver is registered with the bus, the bus' s list of devices is iterated over, and the match callback is called for each device that does not have a driver associated with it.

1.2.6 Device and Driver Lists

The lists of devices and drivers are intended to replace the local lists that many buses keep. They are lists of struct devices and struct device_drivers, respectively. Bus drivers are free to use the lists as they please, but conversion to the bus-specific type may be necessary.

The LDM core provides helper functions for iterating over each list:

```
int bus_for_each_dev(struct bus_type * bus, struct device * start,
                     void * data,
                     int (*fn)(struct device *, void *));

int bus_for_each_drv(struct bus_type * bus, struct device_driver * start,
                     void * data, int (*fn)(struct device_driver *, void␣
↪*));
```

These helpers iterate over the respective list, and call the callback for each device or driver in the list. All list accesses are synchronized by taking the bus's lock (read currently). The reference count on each object in the list is incremented before the callback is called; it is decremented after the next object has been obtained. The lock is not held when calling the callback.

1.2.7 sysfs

There is a top-level directory named 'bus'.

Each bus gets a directory in the bus directory, along with two default directories:

```
/sys/bus/pci/
|-- devices
`-- drivers
```

Drivers registered with the bus get a directory in the bus's drivers directory:

```
/sys/bus/pci/
|-- devices
`-- drivers
    |-- Intel ICH
    |-- Intel ICH Joystick
    |-- agpgart
    `-- e100
```

Each device that is discovered on a bus of that type gets a symlink in the bus's devices directory to the device's directory in the physical hierarchy:

```
/sys/bus/pci/
|-- devices
|   |-- 00:00.0 -> ../../../root/pci0/00:00.0
|   |-- 00:01.0 -> ../../../root/pci0/00:01.0
|   `-- 00:02.0 -> ../../../root/pci0/00:02.0
`-- drivers
```

1.2.8 Exporting Attributes

```
struct bus_attribute {
      struct attribute        attr;
      ssize_t (*show)(struct bus_type *, char * buf);
      ssize_t (*store)(struct bus_type *, const char * buf, size_t count);
};
```

Bus drivers can export attributes using the BUS_ATTR_RW macro that works similarly to the DEVICE_ATTR_RW macro for devices. For example, a definition like this:

```
static BUS_ATTR_RW(debug);
```

is equivalent to declaring:

```
static bus_attribute bus_attr_debug;
```

This can then be used to add and remove the attribute from the bus's sysfs directory using:

```
int bus_create_file(struct bus_type *, struct bus_attribute *);
void bus_remove_file(struct bus_type *, struct bus_attribute *);
```

1.3 Device Classes

1.3.1 Introduction

A device class describes a type of device, like an audio or network device. The following device classes have been identified:

<Insert List of Device Classes Here>

Each device class defines a set of semantics and a programming interface that devices of that class adhere to. Device drivers are the implementation of that programming interface for a particular device on a particular bus.

Device classes are agnostic with respect to what bus a device resides on.

1.3.2 Programming Interface

The device class structure looks like:

```
typedef int (*devclass_add)(struct device *);
typedef void (*devclass_remove)(struct device *);
```

See the kerneldoc for the struct class.

A typical device class definition would look like:

```
struct device_class input_devclass = {
      .name           = "input",
      .add_device     = input_add_device,
      .remove_device  = input_remove_device,
};
```

Each device class structure should be exported in a header file so it can be used by drivers, extensions and interfaces.

Device classes are registered and unregistered with the core using:

```
int devclass_register(struct device_class * cls);
void devclass_unregister(struct device_class * cls);
```

1.3.3 Devices

As devices are bound to drivers, they are added to the device class that the driver belongs to. Before the driver model core, this would typically happen during the driver's probe() callback, once the device has been initialized. It now happens after the probe() callback finishes from the core.

The device is enumerated in the class. Each time a device is added to the class, the class's devnum field is incremented and assigned to the device. The field is never decremented, so if the device is removed from the class and re-added, it will receive a different enumerated value.

The class is allowed to create a class-specific structure for the device and store it in the device's class_data pointer.

There is no list of devices in the device class. Each driver has a list of devices that it supports. The device class has a list of drivers of that particular class. To access all of the devices in the class, iterate over the device lists of each driver in the class.

1.3.4 Device Drivers

Device drivers are added to device classes when they are registered with the core. A driver specifies the class it belongs to by setting the struct device_driver::devclass field.

1.3.5 sysfs directory structure

There is a top-level sysfs directory named 'class'.

Each class gets a directory in the class directory, along with two default subdirectories:

```
class/
`-- input
    |-- devices
    `-- drivers
```

Drivers registered with the class get a symlink in the drivers/ directory that points to the driver's directory (under its bus directory):

```
class/
`-- input
    |-- devices
    `-- drivers
        `-- usb:usb_mouse -> ../../../bus/drivers/usb_mouse/
```

Each device gets a symlink in the devices/ directory that points to the device's directory in the physical hierarchy:

```
class/
`-- input
    |-- devices
    |   `-- 1 -> ../../../root/pci0/00:1f.0/usb_bus/00:1f.2-1:0/
    `-- drivers
```

1.3.6 Exporting Attributes

```
struct devclass_attribute {
      struct attribute        attr;
      ssize_t (*show)(struct device_class *, char * buf, size_t count,␣
↪loff_t off);
      ssize_t (*store)(struct device_class *, const char * buf, size_t␣
↪count, loff_t off);
};
```

Class drivers can export attributes using the DEVCLASS_ATTR macro that works similarly to the DEVICE_ATTR macro for devices. For example, a definition like this:

```
static DEVCLASS_ATTR(debug,0644,show_debug,store_debug);
```

is equivalent to declaring:

```
static devclass_attribute devclass_attr_debug;
```

The bus driver can add and remove the attribute from the class's sysfs directory using:

```
int devclass_create_file(struct device_class *, struct devclass_attribute␣
↪*);
void devclass_remove_file(struct device_class *, struct devclass_attribute␣
↪*);
```

In the example above, the file will be named 'debug' in placed in the class's directory in sysfs.

1.3.7 Interfaces

There may exist multiple mechanisms for accessing the same device of a particular class type. Device interfaces describe these mechanisms.

When a device is added to a device class, the core attempts to add it to every interface that is registered with the device class.

1.4 Device Driver Design Patterns

This document describes a few common design patterns found in device drivers. It is likely that subsystem maintainers will ask driver developers to conform to these design patterns.

1. State Container
2. `container_of()`

1.4.1 1. State Container

While the kernel contains a few device drivers that assume that they will only be probed() once on a certain system (singletons), it is custom to assume that the device the driver binds to will appear in several instances. This means that the probe() function and all callbacks need to be reentrant.

The most common way to achieve this is to use the state container design pattern. It usually has this form:

```
struct foo {
    spinlock_t lock; /* Example member */
    (...)
};

static int foo_probe(...)
{
    struct foo *foo;

    foo = devm_kzalloc(dev, sizeof(*foo), GFP_KERNEL);
    if (!foo)
        return -ENOMEM;
    spin_lock_init(&foo->lock);
    (...)
}
```

This will create an instance of struct foo in memory every time probe() is called. This is our state container for this instance of the device driver. Of course it is then necessary to always pass this instance of the state around to all functions that need access to the state and its members.

For example, if the driver is registering an interrupt handler, you would pass around a pointer to struct foo like this:

```
static irqreturn_t foo_handler(int irq, void *arg)
{
    struct foo *foo = arg;
    (...)
}

static int foo_probe(...)
{
    struct foo *foo;

    (...)
    ret = request_irq(irq, foo_handler, 0, "foo", foo);
}
```

This way you always get a pointer back to the correct instance of foo in your interrupt handler.

1.4.2 2. container_of()

Continuing on the above example we add an offloaded work:

```
struct foo {
    spinlock_t lock;
    struct workqueue_struct *wq;
    struct work_struct offload;
    (...)
};

static void foo_work(struct work_struct *work)
{
    struct foo *foo = container_of(work, struct foo, offload);

    (...)
}

static irqreturn_t foo_handler(int irq, void *arg)
{
    struct foo *foo = arg;

    queue_work(foo->wq, &foo->offload);
    (...)
}

static int foo_probe(...)
{
    struct foo *foo;

    foo->wq = create_singlethread_workqueue("foo-wq");
    INIT_WORK(&foo->offload, foo_work);
    (...)
}
```

The design pattern is the same for an hrtimer or something similar that will return a single argument which is a pointer to a struct member in the callback.

`container_of()` is a macro defined in <linux/kernel.h>

What container_of() does is to obtain a pointer to the containing struct from a pointer to a member by a simple subtraction using the offsetof() macro from standard C, which allows something similar to object oriented behaviours. Notice that the contained member must not be a pointer, but an actual member for this to work.

We can see here that we avoid having global pointers to our struct foo * instance this way, while still keeping the number of parameters passed to the work function to a single pointer.

1.5 The Basic Device Structure

See the kerneldoc for the struct device.

1.5.1 Programming Interface

The bus driver that discovers the device uses this to register the device with the core:

```
int device_register(struct device * dev);
```

The bus should initialize the following fields:

- parent
- name
- bus_id
- bus

A device is removed from the core when its reference count goes to 0. The reference count can be adjusted using:

```
struct device * get_device(struct device * dev);
void put_device(struct device * dev);
```

get_device() will return a pointer to the struct device passed to it if the reference is not already 0 (if it' s in the process of being removed already).

A driver can access the lock in the device structure using:

```
void lock_device(struct device * dev);
void unlock_device(struct device * dev);
```

1.5.2 Attributes

```
struct device_attribute {
      struct attribute        attr;
      ssize_t (*show)(struct device *dev, struct device_attribute *attr,
                      char *buf);
      ssize_t (*store)(struct device *dev, struct device_attribute *attr,
                       const char *buf, size_t count);
};
```

Attributes of devices can be exported by a device driver through sysfs.

Please see Documentation/filesystems/sysfs.rst for more information on how sysfs works.

As explained in Documentation/core-api/kobject.rst, device attributes must be created before the KOBJ_ADD uevent is generated. The only way to realize that is by defining an attribute group.

Attributes are declared using a macro called DEVICE_ATTR:

```
#define DEVICE_ATTR(name,mode,show,store)
```

Example::

```
static DEVICE_ATTR(type, 0444, show_type, NULL);
static DEVICE_ATTR(power, 0644, show_power, store_power);
```

This declares two structures of type struct device_attribute with respective names ‘dev_attr_type’ and ‘dev_attr_power’. These two attributes can be organized as follows into a group:

```
static struct attribute *dev_attrs[] = {
      &dev_attr_type.attr,
      &dev_attr_power.attr,
      NULL,
};

static struct attribute_group dev_attr_group = {
      .attrs = dev_attrs,
};

static const struct attribute_group *dev_attr_groups[] = {
      &dev_attr_group,
      NULL,
};
```

This array of groups can then be associated with a device by setting the group pointer in struct device before `device_register()` is invoked:

```
dev->groups = dev_attr_groups;
device_register(dev);
```

The `device_register()` function will use the ‘groups’ pointer to create the device attributes and the `device_unregister()` function will use this pointer to remove the device attributes.

Word of warning: While the kernel allows `device_create_file()` and `device_remove_file()` to be called on a device at any time, userspace has strict expectations on when attributes get created. When a new device is registered in the kernel, a uevent is generated to notify userspace (like udev) that a new device is available. If attributes are added after the device is registered, then userspace won't get notified and userspace will not know about the new attributes.

This is important for device driver that need to publish additional attributes for a device at driver probe time. If the device driver simply calls `device_create_file()` on the device structure passed to it, then userspace will never be notified of the new attributes.

1.6 Devres - Managed Device Resource

Tejun Heo <teheo@suse.de>

First draft 10 January 2007

1.6.1 1. Intro

devres came up while trying to convert libata to use iomap. Each iomapped address should be kept and unmapped on driver detach. For example, a plain SFF ATA controller (that is, good old PCI IDE) in native mode makes use of 5 PCI BARs and all of them should be maintained.

As with many other device drivers, libata low level drivers have sufficient bugs in ->remove and ->probe failure path. Well, yes, that's probably because libata low level driver developers are lazy bunch, but aren't all low level driver developers? After spending a day fiddling with braindamaged hardware with no document or braindamaged document, if it's finally working, well, it's working.

For one reason or another, low level drivers don't receive as much attention or testing as core code, and bugs on driver detach or initialization failure don't happen often enough to be noticeable. Init failure path is worse because it's much less travelled while needs to handle multiple entry points.

So, many low level drivers end up leaking resources on driver detach and having half broken failure path implementation in ->probe() which would leak resources or even cause oops when failure occurs. iomap adds more to this mix. So do msi and msix.

1.6.2 2. Devres

devres is basically linked list of arbitrarily sized memory areas associated with a struct device. Each devres entry is associated with a release function. A devres can be released in several ways. No matter what, all devres entries are released on driver detach. On release, the associated release function is invoked and then the devres entry is freed.

Managed interface is created for resources commonly used by device drivers using devres. For example, coherent DMA memory is acquired using

dma_alloc_coherent(). The managed version is called dmam_alloc_coherent(). It is identical to dma_alloc_coherent() except for the DMA memory allocated using it is managed and will be automatically released on driver detach. Implementation looks like the following:

```
struct dma_devres {
      size_t          size;
      void            *vaddr;
      dma_addr_t      dma_handle;
};

static void dmam_coherent_release(struct device *dev, void *res)
{
      struct dma_devres *this = res;

      dma_free_coherent(dev, this->size, this->vaddr, this->dma_handle);
}

dmam_alloc_coherent(dev, size, dma_handle, gfp)
{
      struct dma_devres *dr;
      void *vaddr;

      dr = devres_alloc(dmam_coherent_release, sizeof(*dr), gfp);
      ...

      /* alloc DMA memory as usual */
      vaddr = dma_alloc_coherent(...);
      ...

      /* record size, vaddr, dma_handle in dr */
      dr->vaddr = vaddr;
      ...

      devres_add(dev, dr);

      return vaddr;
}
```

If a driver uses dmam_alloc_coherent(), the area is guaranteed to be freed whether initialization fails half-way or the device gets detached. If most resources are acquired using managed interface, a driver can have much simpler init and exit code. Init path basically looks like the following:

```
my_init_one()
{
      struct mydev *d;

      d = devm_kzalloc(dev, sizeof(*d), GFP_KERNEL);
      if (!d)
              return -ENOMEM;

      d->ring = dmam_alloc_coherent(...);
      if (!d->ring)
              return -ENOMEM;
```

(continues on next page)

(continued from previous page)

```
      if (check something)
              return -EINVAL;
      ...

      return register_to_upper_layer(d);
}
```

And exit path:

```
my_remove_one()
{
      unregister_from_upper_layer(d);
      shutdown_my_hardware();
}
```

As shown above, low level drivers can be simplified a lot by using devres. Complexity is shifted from less maintained low level drivers to better maintained higher layer. Also, as init failure path is shared with exit path, both can get more testing.

Note though that when converting current calls or assignments to managed devm_* versions it is up to you to check if internal operations like allocating memory, have failed. Managed resources pertains to the freeing of these resources only - all other checks needed are still on you. In some cases this may mean introducing checks that were not necessary before moving to the managed devm_* calls.

1.6.3 3. Devres group

Devres entries can be grouped using devres group. When a group is released, all contained normal devres entries and properly nested groups are released. One usage is to rollback series of acquired resources on failure. For example:

```
 if (!devres_open_group(dev, NULL, GFP_KERNEL))
       return -ENOMEM;

 acquire A;
 if (failed)
       goto err;

 acquire B;
 if (failed)
       goto err;
 ...

 devres_remove_group(dev, NULL);
 return 0;

err:
 devres_release_group(dev, NULL);
 return err_code;
```

As resource acquisition failure usually means probe failure, constructs like above are usually useful in midlayer driver (e.g. libata core layer) where interface func-

tion shouldn't have side effect on failure. For LLDs, just returning error code suffices in most cases.

Each group is identified by void *id. It can either be explicitly specified by @id argument to `devres_open_group()` or automatically created by passing NULL as @id as in the above example. In both cases, `devres_open_group()` returns the group's id. The returned id can be passed to other devres functions to select the target group. If NULL is given to those functions, the latest open group is selected.

For example, you can do something like the following:

```
int my_midlayer_create_something()
{
      if (!devres_open_group(dev, my_midlayer_create_something, GFP_
↪KERNEL))
              return -ENOMEM;

      ...

      devres_close_group(dev, my_midlayer_create_something);
      return 0;
}

void my_midlayer_destroy_something()
{
      devres_release_group(dev, my_midlayer_create_something);
}
```

1.6.4 4. Details

Lifetime of a devres entry begins on devres allocation and finishes when it is released or destroyed (removed and freed) - no reference counting.

devres core guarantees atomicity to all basic devres operations and has support for single-instance devres types (atomic lookup-and-add-if-not-found). Other than that, synchronizing concurrent accesses to allocated devres data is caller's responsibility. This is usually non-issue because bus ops and resource allocations already do the job.

For an example of single-instance devres type, read pcim_iomap_table() in lib/devres.c.

All devres interface functions can be called without context if the right gfp mask is given.

1.6.5 5. Overhead

Each devres bookkeeping info is allocated together with requested data area. With debug option turned off, bookkeeping info occupies 16 bytes on 32bit machines and 24 bytes on 64bit (three pointers rounded up to ull alignment). If singly linked list is used, it can be reduced to two pointers (8 bytes on 32bit, 16 bytes on 64bit).

Each devres group occupies 8 pointers. It can be reduced to 6 if singly linked list is used.

Memory space overhead on ahci controller with two ports is between 300 and 400 bytes on 32bit machine after naive conversion (we can certainly invest a bit more effort into libata core layer).

1.6.6 6. List of managed interfaces

CLOCK devm_clk_get() devm_clk_get_optional() devm_clk_put() devm_clk_bulk_get() devm_clk_bulk_get_all() devm_clk_bulk_get_optional() devm_get_clk_from_childl() devm_clk_hw_register() devm_of_clk_add_hw_provider() devm_clk_hw_register_clkdev()

DMA dmaenginem_async_device_register() dmam_alloc_coherent() dmam_alloc_attrs() dmam_free_coherent() dmam_pool_create() dmam_pool_destroy()

DRM devm_drm_dev_init()

GPIO devm_gpiod_get() devm_gpiod_get_array() devm_gpiod_get_array_optional() devm_gpiod_get_index() devm_gpiod_get_index_optional() devm_gpiod_get_optional() devm_gpiod_put() devm_gpiod_unhinge() devm_gpiochip_add_data() devm_gpio_request() devm_gpio_request_one() devm_gpio_free()

I2C devm_i2c_new_dummy_device()

IIO devm_iio_device_alloc() devm_iio_device_register() devm_iio_kfifo_allocate() devm_iio_triggered_buffer_setup() devm_iio_trigger_alloc() devm_iio_trigger_register() devm_iio_channel_get() devm_iio_channel_get_all()

1.7 Device Drivers

See the kerneldoc for the struct device_driver.

1.7.1 Allocation

Device drivers are statically allocated structures. Though there may be multiple devices in a system that a driver supports, struct device_driver represents the driver as a whole (not a particular device instance).

1.7.2 Initialization

The driver must initialize at least the name and bus fields. It should also initialize the devclass field (when it arrives), so it may obtain the proper linkage internally. It should also initialize as many of the callbacks as possible, though each is optional.

1.7.3 Declaration

As stated above, struct device_driver objects are statically allocated. Below is an example declaration of the eepro100 driver. This declaration is hypothetical only; it relies on the driver being converted completely to the new model:

```
static struct device_driver eepro100_driver = {
       .name           = "eepro100",
       .bus            = &pci_bus_type,

       .probe          = eepro100_probe,
       .remove                 = eepro100_remove,
       .suspend                = eepro100_suspend,
       .resume                 = eepro100_resume,
};
```

Most drivers will not be able to be converted completely to the new model because the bus they belong to has a bus-specific structure with bus-specific fields that cannot be generalized.

The most common example of this are device ID structures. A driver typically defines an array of device IDs that it supports. The format of these structures and the semantics for comparing device IDs are completely bus-specific. Defining them as bus-specific entities would sacrifice type-safety, so we keep bus-specific structures around.

Bus-specific drivers should include a generic struct device_driver in the definition of the bus-specific driver. Like this:

```
struct pci_driver {
       const struct pci_device_id *id_table;
       struct device_driver     driver;
};
```

A definition that included bus-specific fields would look like (using the eepro100 driver again):

```
static struct pci_driver eepro100_driver = {
       .id_table       = eepro100_pci_tbl,
       .driver                 = {
              .name           = "eepro100",
```

(continues on next page)

(continued from previous page)

```
                .bus            = &pci_bus_type,
                .probe          = eepro100_probe,
                .remove         = eepro100_remove,
                .suspend        = eepro100_suspend,
                .resume         = eepro100_resume,
        },
};
```

Some may find the syntax of embedded struct initialization awkward or even a bit ugly. So far, it's the best way we've found to do what we want…

1.7.4 Registration

```
int driver_register(struct device_driver *drv);
```

The driver registers the structure on startup. For drivers that have no bus-specific fields (i.e. don't have a bus-specific driver structure), they would use driver_register and pass a pointer to their struct device_driver object.

Most drivers, however, will have a bus-specific structure and will need to register with the bus using something like pci_driver_register.

It is important that drivers register their driver structure as early as possible. Registration with the core initializes several fields in the struct device_driver object, including the reference count and the lock. These fields are assumed to be valid at all times and may be used by the device model core or the bus driver.

1.7.5 Transition Bus Drivers

By defining wrapper functions, the transition to the new model can be made easier. Drivers can ignore the generic structure altogether and let the bus wrapper fill in the fields. For the callbacks, the bus can define generic callbacks that forward the call to the bus-specific callbacks of the drivers.

This solution is intended to be only temporary. In order to get class information in the driver, the drivers must be modified anyway. Since converting drivers to the new model should reduce some infrastructural complexity and code size, it is recommended that they are converted as class information is added.

1.7.6 Access

Once the object has been registered, it may access the common fields of the object, like the lock and the list of devices:

```
int driver_for_each_dev(struct device_driver *drv, void *data,
                        int (*callback)(struct device *dev, void *data));
```

The devices field is a list of all the devices that have been bound to the driver. The LDM core provides a helper function to operate on all the devices a driver controls. This helper locks the driver on each node access, and does proper reference counting on each device as it accesses it.

1.7.7 sysfs

When a driver is registered, a sysfs directory is created in its bus' s directory. In this directory, the driver can export an interface to userspace to control operation of the driver on a global basis; e.g. toggling debugging output in the driver.

A future feature of this directory will be a 'devices' directory. This directory will contain symlinks to the directories of devices it supports.

1.7.8 Callbacks

```
int     (*probe)        (struct device *dev);
```

The probe() entry is called in task context, with the bus' s rwsem locked and the driver partially bound to the device. Drivers commonly use `container_of()` to convert "dev" to a bus-specific type, both in probe() and other routines. That type often provides device resource data, such as pci_dev.resource[] or platform_device.resources, which is used in addition to dev->platform_data to initialize the driver.

This callback holds the driver-specific logic to bind the driver to a given device. That includes verifying that the device is present, that it' s a version the driver can handle, that driver data structures can be allocated and initialized, and that any hardware can be initialized. Drivers often store a pointer to their state with dev_set_drvdata(). When the driver has successfully bound itself to that device, then probe() returns zero and the driver model code will finish its part of binding the driver to that device.

A driver' s probe() may return a negative errno value to indicate that the driver did not bind to this device, in which case it should have released all resources it allocated.

Optionally, probe() may return -EPROBE_DEFER if the driver depends on resources that are not yet available (e.g., supplied by a driver that hasn' t initialized yet). The driver core will put the device onto the deferred probe list and will try to call it again later. If a driver must defer, it should return -EPROBE_DEFER as early as possible to reduce the amount of time spent on setup work that will need to be unwound and reexecuted at a later time.

> **Warning:** -EPROBE_DEFER must not be returned if probe() has already created child devices, even if those child devices are removed again in a cleanup path. If -EPROBE_DEFER is returned after a child device has been registered, it may result in an infinite loop of .probe() calls to the same driver.

```
void    (*sync_state)   (struct device *dev);
```

sync_state is called only once for a device. It' s called when all the consumer devices of the device have successfully probed. The list of consumers of the device is obtained by looking at the device links connecting that device to its consumer devices.

The first attempt to call sync_state() is made during late_initcall_sync() to give firmware and drivers time to link devices to each other. During the first attempt at calling sync_state(), if all the consumers of the device at that point in time have already probed successfully, sync_state() is called right away. If there are no consumers of the device during the first attempt, that too is considered as "all consumers of the device have probed" and sync_state() is called right away.

If during the first attempt at calling sync_state() for a device, there are still consumers that haven't probed successfully, the sync_state() call is postponed and reattempted in the future only when one or more consumers of the device probe successfully. If during the reattempt, the driver core finds that there are one or more consumers of the device that haven't probed yet, then sync_state() call is postponed again.

A typical use case for sync_state() is to have the kernel cleanly take over management of devices from the bootloader. For example, if a device is left on and at a particular hardware configuration by the bootloader, the device's driver might need to keep the device in the boot configuration until all the consumers of the device have probed. Once all the consumers of the device have probed, the device's driver can synchronize the hardware state of the device to match the aggregated software state requested by all the consumers. Hence the name sync_state().

While obvious examples of resources that can benefit from sync_state() include resources such as regulator, sync_state() can also be useful for complex resources like IOMMUs. For example, IOMMUs with multiple consumers (devices whose addresses are remapped by the IOMMU) might need to keep their mappings fixed at (or additive to) the boot configuration until all its consumers have probed.

While the typical use case for sync_state() is to have the kernel cleanly take over management of devices from the bootloader, the usage of sync_state() is not restricted to that. Use it whenever it makes sense to take an action after all the consumers of a device have probed:

```
::
```

int (*remove) (struct device *dev);

remove is called to unbind a driver from a device. This may be called if a device is physically removed from the system, if the driver module is being unloaded, during a reboot sequence, or in other cases.

It is up to the driver to determine if the device is present or not. It should free any resources allocated specifically for the device; i.e. anything in the device's driver_data field.

If the device is still present, it should quiesce the device and place it into a supported low-power state.

```
int     (*suspend)      (struct device *dev, pm_message_t state);
```

suspend is called to put the device in a low power state.

```
int     (*resume)       (struct device *dev);
```

Resume is used to bring a device back from a low power state.

1.7.9 Attributes

```
struct driver_attribute {
        struct attribute        attr;
        ssize_t (*show)(struct device_driver *driver, char *buf);
        ssize_t (*store)(struct device_driver *, const char *buf, size_t␣
↪count);
};
```

Device drivers can export attributes via their sysfs directories. Drivers can declare attributes using a DRIVER_ATTR_RW and DRIVER_ATTR_RO macro that works identically to the DEVICE_ATTR_RW and DEVICE_ATTR_RO macros.

Example:

```
DRIVER_ATTR_RW(debug);
```

This is equivalent to declaring:

```
struct driver_attribute driver_attr_debug;
```

This can then be used to add and remove the attribute from the driver's directory using:

```
int driver_create_file(struct device_driver *, const struct driver_
↪attribute *);
void driver_remove_file(struct device_driver *, const struct driver_
↪attribute *);
```

1.8 The Linux Kernel Device Model

Patrick Mochel <mochel@digitalimplant.org>

Drafted 26 August 2002 Updated 31 January 2006

1.8.1 Overview

The Linux Kernel Driver Model is a unification of all the disparate driver models that were previously used in the kernel. It is intended to augment the bus-specific drivers for bridges and devices by consolidating a set of data and operations into globally accessible data structures.

Traditional driver models implemented some sort of tree-like structure (sometimes just a list) for the devices they control. There wasn't any uniformity across the different bus types.

The current driver model provides a common, uniform data model for describing a bus and the devices that can appear under the bus. The unified bus model includes a set of common attributes which all busses carry, and a set of common callbacks, such as device discovery during bus probing, bus shutdown, bus power management, etc.

The common device and bridge interface reflects the goals of the modern computer: namely the ability to do seamless device “plug and play”, power management, and hot plug. In particular, the model dictated by Intel and Microsoft (namely ACPI) ensures that almost every device on almost any bus on an x86-compatible system can work within this paradigm. Of course, not every bus is able to support all such operations, although most buses support most of those operations.

1.8.2 Downstream Access

Common data fields have been moved out of individual bus layers into a common data structure. These fields must still be accessed by the bus layers, and sometimes by the device-specific drivers.

Other bus layers are encouraged to do what has been done for the PCI layer. struct pci_dev now looks like this:

```
struct pci_dev {
      ...

      struct device dev;     /* Generic device interface */
      ...
};
```

Note first that the struct device dev within the struct pci_dev is statically allocated. This means only one allocation on device discovery.

Note also that that struct device dev is not necessarily defined at the front of the pci_dev structure. This is to make people think about what they’re doing when switching between the bus driver and the global driver, and to discourage meaningless and incorrect casts between the two.

The PCI bus layer freely accesses the fields of struct device. It knows about the structure of struct pci_dev, and it should know the structure of struct device. Individual PCI device drivers that have been converted to the current driver model generally do not and should not touch the fields of struct device, unless there is a compelling reason to do so.

The above abstraction prevents unnecessary pain during transitional phases. If it were not done this way, then when a field was renamed or removed, every downstream driver would break. On the other hand, if only the bus layer (and not the device layer) accesses the struct device, it is only the bus layer that needs to change.

1.8.3 User Interface

By virtue of having a complete hierarchical view of all the devices in the system, exporting a complete hierarchical view to userspace becomes relatively easy. This has been accomplished by implementing a special purpose virtual file system named sysfs.

Almost all mainstream Linux distros mount this filesystem automatically; you can see some variation of the following in the output of the "mount" command:

```
$ mount
...
none on /sys type sysfs (rw,noexec,nosuid,nodev)
...
$
```

The auto-mounting of sysfs is typically accomplished by an entry similar to the following in the /etc/fstab file:

```
none          /sys    sysfs    defaults               0 0
```

or something similar in the /lib/init/fstab file on Debian-based systems:

```
none            /sys    sysfs    nodev,noexec,nosuid    0 0
```

If sysfs is not automatically mounted, you can always do it manually with:

```
# mount -t sysfs sysfs /sys
```

Whenever a device is inserted into the tree, a directory is created for it. This directory may be populated at each layer of discovery - the global layer, the bus layer, or the device layer.

The global layer currently creates two files - 'name' and 'power'. The former only reports the name of the device. The latter reports the current power state of the device. It will also be used to set the current power state.

The bus layer may also create files for the devices it finds while probing the bus. For example, the PCI layer currently creates 'irq' and 'resource' files for each PCI device.

A device-specific driver may also export files in its directory to expose device-specific data or tunable interfaces.

More information about the sysfs directory layout can be found in the other documents in this directory and in the file Documentation/filesystems/sysfs.rst.

1.9 Platform Devices and Drivers

See <linux/platform_device.h> for the driver model interface to the platform bus: platform_device, and platform_driver. This pseudo-bus is used to connect devices on busses with minimal infrastructure, like those used to integrate peripherals on many system-on-chip processors, or some "legacy" PC interconnects; as opposed to large formally specified ones like PCI or USB.

1.9.1 Platform devices

Platform devices are devices that typically appear as autonomous entities in the system. This includes legacy port-based devices and host bridges to peripheral buses, and most controllers integrated into system-on-chip platforms. What they usually have in common is direct addressing from a CPU bus. Rarely, a platform_device will be connected through a segment of some other kind of bus; but its registers will still be directly addressable.

Platform devices are given a name, used in driver binding, and a list of resources such as addresses and IRQs:

```
struct platform_device {
      const char      *name;
      u32             id;
      struct device   dev;
      u32             num_resources;
      struct resource *resource;
};
```

1.9.2 Platform drivers

Platform drivers follow the standard driver model convention, where discovery/enumeration is handled outside the drivers, and drivers provide probe() and remove() methods. They support power management and shutdown notifications using the standard conventions:

```
struct platform_driver {
      int (*probe)(struct platform_device *);
      int (*remove)(struct platform_device *);
      void (*shutdown)(struct platform_device *);
      int (*suspend)(struct platform_device *, pm_message_t state);
      int (*suspend_late)(struct platform_device *, pm_message_t state);
      int (*resume_early)(struct platform_device *);
      int (*resume)(struct platform_device *);
      struct device_driver driver;
};
```

Note that probe() should in general verify that the specified device hardware actually exists; sometimes platform setup code can't be sure. The probing can use device resources, including clocks, and device platform_data.

Platform drivers register themselves the normal way:

```
int platform_driver_register(struct platform_driver *drv);
```

Or, in common situations where the device is known not to be hot-pluggable, the probe() routine can live in an init section to reduce the driver's runtime memory footprint:

```
int platform_driver_probe(struct platform_driver *drv,
                  int (*probe)(struct platform_device *))
```

Kernel modules can be composed of several platform drivers. The platform core provides helpers to register and unregister an array of drivers:

```
int __platform_register_drivers(struct platform_driver * const *drivers,
                                unsigned int count, struct module *owner);
void platform_unregister_drivers(struct platform_driver * const *drivers,
                                 unsigned int count);
```

If one of the drivers fails to register, all drivers registered up to that point will be unregistered in reverse order. Note that there is a convenience macro that passes THIS_MODULE as owner parameter:

```
#define platform_register_drivers(drivers, count)
```

1.9.3 Device Enumeration

As a rule, platform specific (and often board-specific) setup code will register platform devices:

```
int platform_device_register(struct platform_device *pdev);

int platform_add_devices(struct platform_device **pdevs, int ndev);
```

The general rule is to register only those devices that actually exist, but in some cases extra devices might be registered. For example, a kernel might be configured to work with an external network adapter that might not be populated on all boards, or likewise to work with an integrated controller that some boards might not hook up to any peripherals.

In some cases, boot firmware will export tables describing the devices that are populated on a given board. Without such tables, often the only way for system setup code to set up the correct devices is to build a kernel for a specific target board. Such board-specific kernels are common with embedded and custom systems development.

In many cases, the memory and IRQ resources associated with the platform device are not enough to let the device's driver work. Board setup code will often provide additional information using the device's platform_data field to hold additional information.

Embedded systems frequently need one or more clocks for platform devices, which are normally kept off until they're actively needed (to save power). System setup also associates those clocks with the device, so that that calls to clk_get(&pdev->dev, clock_name) return them as needed.

1.9.4 Legacy Drivers: Device Probing

Some drivers are not fully converted to the driver model, because they take on a non-driver role: the driver registers its platform device, rather than leaving that for system infrastructure. Such drivers can't be hotplugged or coldplugged, since those mechanisms require device creation to be in a different system component than the driver.

The only "good" reason for this is to handle older system designs which, like original IBM PCs, rely on error-prone "probe-the-hardware" models for hardware configuration. Newer systems have largely abandoned that model, in favor of bus-level support for dynamic configuration (PCI, USB), or device tables provided by the boot firmware (e.g. PNPACPI on x86). There are too many conflicting options about what might be where, and even educated guesses by an operating system will be wrong often enough to make trouble.

This style of driver is discouraged. If you're updating such a driver, please try to move the device enumeration to a more appropriate location, outside the driver. This will usually be cleanup, since such drivers tend to already have "normal" modes, such as ones using device nodes that were created by PNP or by platform device setup.

None the less, there are some APIs to support such legacy drivers. Avoid using these calls except with such hotplug-deficient drivers:

```
struct platform_device *platform_device_alloc(
                const char *name, int id);
```

You can use `platform_device_alloc()` to dynamically allocate a device, which you will then initialize with resources and `platform_device_register()`. A better solution is usually:

```
struct platform_device *platform_device_register_simple(
                const char *name, int id,
                struct resource *res, unsigned int nres);
```

You can use `platform_device_register_simple()` as a one-step call to allocate and register a device.

1.9.5 Device Naming and Driver Binding

The platform_device.dev.bus_id is the canonical name for the devices. It's built from two components:

- platform_device.name ⋯which is also used to for driver matching.
- platform_device.id ⋯the device instance number, or else "-1"to indicate there's only one.

These are concatenated, so name/id "serial"/0 indicates bus_id "serial.0", and "serial/3" indicates bus_id "serial.3"; both would use the platform_driver named "serial". While "my_rtc"/-1 would be bus_id "my_rtc" (no instance id) and use the platform_driver called "my_rtc".

Driver binding is performed automatically by the driver core, invoking driver probe() after finding a match between device and driver. If the probe() succeeds, the driver and device are bound as usual. There are three different ways to find such a match:

- Whenever a device is registered, the drivers for that bus are checked for matches. Platform devices should be registered very early during system boot.
- When a driver is registered using platform_driver_register(), all unbound devices on that bus are checked for matches. Drivers usually register later during booting, or by module loading.
- Registering a driver using platform_driver_probe() works just like using platform_driver_register(), except that the driver won't be probed later if another device registers. (Which is OK, since this interface is only for use with non-hotpluggable devices.)

1.9.6 Early Platform Devices and Drivers

The early platform interfaces provide platform data to platform device drivers early on during the system boot. The code is built on top of the early_param() command line parsing and can be executed very early on.

Example: "earlyprintk" class early serial console in 6 steps

1.9.7 1. Registering early platform device data

The architecture code registers platform device data using the function early_platform_add_devices(). In the case of early serial console this should be hardware configuration for the serial port. Devices registered at this point will later on be matched against early platform drivers.

1.9.8 2. Parsing kernel command line

The architecture code calls parse_early_param() to parse the kernel command line. This will execute all matching early_param() callbacks. User specified early platform devices will be registered at this point. For the early serial console case the user can specify port on the kernel command line as "earlyprintk=serial.0" where "earlyprintk" is the class string, "serial" is the name of the platform driver and 0 is the platform device id. If the id is -1 then the dot and the id can be omitted.

1.9.9 3. Installing early platform drivers belonging to a certain class

The architecture code may optionally force registration of all early platform drivers belonging to a certain class using the function early_platform_driver_register_all(). User specified devices from step 2 have priority over these. This step is omitted by the serial driver example since the early serial driver code should be disabled unless the user has specified port on the kernel command line.

1.9.10 4. Early platform driver registration

Compiled-in platform drivers making use of early_platform_init() are automatically registered during step 2 or 3. The serial driver example should use early_platform_init(“earlyprintk” , &platform_driver).

1.9.11 5. Probing of early platform drivers belonging to a certain class

The architecture code calls early_platform_driver_probe() to match registered early platform devices associated with a certain class with registered early platform drivers. Matched devices will get probed(). This step can be executed at any point during the early boot. As soon as possible may be good for the serial port case.

1.9.12 6. Inside the early platform driver probe()

The driver code needs to take special care during early boot, especially when it comes to memory allocation and interrupt registration. The code in the probe() function can use is_early_platform_device() to check if it is called at early platform device or at the regular platform device time. The early serial driver performs register_console() at this point.

For further information, see <linux/platform_device.h>.

1.10 Porting Drivers to the New Driver Model

Patrick Mochel

7 January 2003

Overview

Please refer to Documentation/driver-api/driver-model/*.rst for definitions of various driver types and concepts.

Most of the work of porting devices drivers to the new model happens at the bus driver layer. This was intentional, to minimize the negative effect on kernel drivers, and to allow a gradual transition of bus drivers.

In a nutshell, the driver model consists of a set of objects that can be embedded in larger, bus-specific objects. Fields in these generic objects can replace fields in the bus-specific objects.

The generic objects must be registered with the driver model core. By doing so, they will exported via the sysfs filesystem. sysfs can be mounted by doing:

```
# mount -t sysfs sysfs /sys
```

The Process

Step 0: Read include/linux/device.h for object and function definitions.

Step 1: Registering the bus driver.

- Define a struct bus_type for the bus driver:

```
struct bus_type pci_bus_type = {
      .name           = "pci",
};
```

- Register the bus type.

  This should be done in the initialization function for the bus type, which is usually the `module_init()`, or equivalent, function:

```
static int __init pci_driver_init(void)
{
        return bus_register(&pci_bus_type);
}

subsys_initcall(pci_driver_init);
```

  The bus type may be unregistered (if the bus driver may be compiled as a module) by doing:

```
bus_unregister(&pci_bus_type);
```

- Export the bus type for others to use.

  Other code may wish to reference the bus type, so declare it in a shared header file and export the symbol.

From include/linux/pci.h:

```
extern struct bus_type pci_bus_type;
```

From file the above code appears in:

```
EXPORT_SYMBOL(pci_bus_type);
```

- This will cause the bus to show up in /sys/bus/pci/ with two subdirectories: ‘devices’ and ‘drivers’ :

```
# tree -d /sys/bus/pci/
/sys/bus/pci/
|-- devices
`-- drivers
```

Step 2: Registering Devices.

struct device represents a single device. It mainly contains metadata describing the relationship the device has to other entities.

- Embed a struct device in the bus-specific device type:

```
struct pci_dev {
       ...
       struct  device  dev;            /* Generic device interface */
       ...
};
```

  It is recommended that the generic device not be the first item in the struct to discourage programmers from doing mindless casts between the object types. Instead macros, or inline functions, should be created to convert from the generic object type:

```
#define to_pci_dev(n) container_of(n, struct pci_dev, dev)

or

static inline struct pci_dev * to_pci_dev(struct kobject * kobj)
{
    return container_of(n, struct pci_dev, dev);
}
```

  This allows the compiler to verify type-safety of the operations that are performed (which is Good).

- Initialize the device on registration.

  When devices are discovered or registered with the bus type, the bus driver should initialize the generic device. The most important things to initialize are the bus_id, parent, and bus fields.

  The bus_id is an ASCII string that contains the device's address on the bus. The format of this string is bus-specific. This is necessary for representing devices in sysfs.

  parent is the physical parent of the device. It is important that the bus driver sets this field correctly.

  The driver model maintains an ordered list of devices that it uses for power management. This list must be in order to guarantee that devices are shutdown before their physical parents, and vice versa. The order of this list is determined by the parent of registered devices.

  Also, the location of the device's sysfs directory depends on a device's parent. sysfs exports a directory structure that mirrors the device hierarchy. Accurately setting the parent guarantees that sysfs will accurately represent the hierarchy.

  The device's bus field is a pointer to the bus type the device belongs to. This should be set to the bus_type that was declared and initialized before.

  Optionally, the bus driver may set the device's name and release fields.

  The name field is an ASCII string describing the device, like

"ATI Technologies Inc Radeon QD"

The release field is a callback that the driver model core calls when the device has been removed, and all references to it have been released. More on this in a moment.

- Register the device.

  Once the generic device has been initialized, it can be registered with the driver model core by doing:

```
device_register(&dev->dev);
```

  It can later be unregistered by doing:

```
device_unregister(&dev->dev);
```

  This should happen on buses that support hotpluggable devices. If a bus driver unregisters a device, it should not immediately free it. It should instead wait for the driver model core to call the device's release method, then free the bus-specific object. (There may be other code that is currently referencing the device structure, and it would be rude to free the device while that is happening).

  When the device is registered, a directory in sysfs is created. The PCI tree in sysfs looks like:

```
/sys/devices/pci0/
|-- 00:00.0
|-- 00:01.0
|   `-- 01:00.0
|-- 00:02.0
|   `-- 02:1f.0
|       `-- 03:00.0
|-- 00:1e.0
|   `-- 04:04.0
|-- 00:1f.0
|-- 00:1f.1
|   |-- ide0
|   |   |-- 0.0
|   |   `-- 0.1
|   `-- ide1
|       `-- 1.0
|-- 00:1f.2
|-- 00:1f.3
`-- 00:1f.5
```

  Also, symlinks are created in the bus's 'devices' directory that point to the device's directory in the physical hierarchy:

```
/sys/bus/pci/devices/
|-- 00:00.0 -> ../../../devices/pci0/00:00.0
|-- 00:01.0 -> ../../../devices/pci0/00:01.0
|-- 00:02.0 -> ../../../devices/pci0/00:02.0
|-- 00:1e.0 -> ../../../devices/pci0/00:1e.0
|-- 00:1f.0 -> ../../../devices/pci0/00:1f.0
|-- 00:1f.1 -> ../../../devices/pci0/00:1f.1
```

(continues on next page)

(continued from previous page)

```
|-- 00:1f.2 -> ../../../devices/pci0/00:1f.2
|-- 00:1f.3 -> ../../../devices/pci0/00:1f.3
|-- 00:1f.5 -> ../../../devices/pci0/00:1f.5
|-- 01:00.0 -> ../../../devices/pci0/00:01.0/01:00.0
|-- 02:1f.0 -> ../../../devices/pci0/00:02.0/02:1f.0
|-- 03:00.0 -> ../../../devices/pci0/00:02.0/02:1f.0/03:00.0
`-- 04:04.0 -> ../../../devices/pci0/00:1e.0/04:04.0
```

Step 3: Registering Drivers.

struct device_driver is a simple driver structure that contains a set of operations that the driver model core may call.

- Embed a struct device_driver in the bus-specific driver.

  Just like with devices, do something like:

```
struct pci_driver {
       ...
       struct device_driver    driver;
};
```

- Initialize the generic driver structure.

  When the driver registers with the bus (e.g. doing pci_register_driver()), initialize the necessary fields of the driver: the name and bus fields.

- Register the driver.

  After the generic driver has been initialized, call:

```
driver_register(&drv->driver);
```

  to register the driver with the core.

  When the driver is unregistered from the bus, unregister it from the core by doing:

```
driver_unregister(&drv->driver);
```

  Note that this will block until all references to the driver have gone away. Normally, there will not be any.

- Sysfs representation.

  Drivers are exported via sysfs in their bus' s 'driver' s directory. For example:

```
/sys/bus/pci/drivers/
|-- 3c59x
|-- Ensoniq AudioPCI
|-- agpgart-amdk7
|-- e100
`-- serial
```

Step 4: Define Generic Methods for Drivers.

struct device_driver defines a set of operations that the driver model core calls. Most of these operations are probably similar to operations the bus already defines

for drivers, but taking different parameters.

It would be difficult and tedious to force every driver on a bus to simultaneously convert their drivers to generic format. Instead, the bus driver should define single instances of the generic methods that forward call to the bus-specific drivers. For instance:

```
static int pci_device_remove(struct device * dev)
{
        struct pci_dev * pci_dev = to_pci_dev(dev);
        struct pci_driver * drv = pci_dev->driver;

        if (drv) {
                if (drv->remove)
                        drv->remove(pci_dev);
                pci_dev->driver = NULL;
        }
        return 0;
}
```

The generic driver should be initialized with these methods before it is registered:

```
/* initialize common driver fields */
drv->driver.name = drv->name;
drv->driver.bus = &pci_bus_type;
drv->driver.probe = pci_device_probe;
drv->driver.resume = pci_device_resume;
drv->driver.suspend = pci_device_suspend;
drv->driver.remove = pci_device_remove;

/* register with core */
driver_register(&drv->driver);
```

Ideally, the bus should only initialize the fields if they are not already set. This allows the drivers to implement their own generic methods.

Step 5: Support generic driver binding.

The model assumes that a device or driver can be dynamically registered with the bus at any time. When registration happens, devices must be bound to a driver, or drivers must be bound to all devices that it supports.

A driver typically contains a list of device IDs that it supports. The bus driver compares these IDs to the IDs of devices registered with it. The format of the device IDs, and the semantics for comparing them are bus-specific, so the generic model does attempt to generalize them.

Instead, a bus may supply a method in struct bus_type that does the comparison:

```
int (*match)(struct device * dev, struct device_driver * drv);
```

match should return positive value if the driver supports the device, and zero otherwise. It may also return error code (for example -EPROBE_DEFER) if determining that given driver supports the device is not possible.

When a device is registered, the bus' s list of drivers is iterated over. bus->match() is called for each one until a match is found.

When a driver is registered, the bus's list of devices is iterated over. bus->match() is called for each device that is not already claimed by a driver.

When a device is successfully bound to a driver, device->driver is set, the device is added to a per-driver list of devices, and a symlink is created in the driver's sysfs directory that points to the device's physical directory:

```
/sys/bus/pci/drivers/
|-- 3c59x
|   `-- 00:0b.0 -> ../../../../devices/pci0/00:0b.0
|-- Ensoniq AudioPCI
|-- agpgart-amdk7
|   `-- 00:00.0 -> ../../../../devices/pci0/00:00.0
|-- e100
|   `-- 00:0c.0 -> ../../../../devices/pci0/00:0c.0
`-- serial
```

This driver binding should replace the existing driver binding mechanism the bus currently uses.

Step 6: Supply a hotplug callback.

Whenever a device is registered with the driver model core, the userspace program /sbin/hotplug is called to notify userspace. Users can define actions to perform when a device is inserted or removed.

The driver model core passes several arguments to userspace via environment variables, including

- ACTION: set to 'add' or 'remove'
- DEVPATH: set to the device's physical path in sysfs.

A bus driver may also supply additional parameters for userspace to consume. To do this, a bus must implement the 'hotplug' method in struct bus_type:

```
int (*hotplug) (struct device *dev, char **envp,
                int num_envp, char *buffer, int buffer_size);
```

This is called immediately before /sbin/hotplug is executed.

Step 7: Cleaning up the bus driver.

The generic bus, device, and driver structures provide several fields that can replace those defined privately to the bus driver.

- Device list.

struct bus_type contains a list of all devices registered with the bus type. This includes all devices on all instances of that bus type. An internal list that the bus uses may be removed, in favor of using this one.

The core provides an iterator to access these devices:

```
int bus_for_each_dev(struct bus_type * bus, struct device * start,
                     void * data, int (*fn)(struct device *, void *));
```

- Driver list.

struct bus_type also contains a list of all drivers registered with it. An internal list of drivers that the bus driver maintains may be removed in favor of using the generic one.

The drivers may be iterated over, like devices:

```
int bus_for_each_drv(struct bus_type * bus, struct device_driver * start,
                     void * data, int (*fn)(struct device_driver *, void␣
↪*));
```

Please see drivers/base/bus.c for more information.

- rwsem

struct bus_type contains an rwsem that protects all core accesses to the device and driver lists. This can be used by the bus driver internally, and should be used when accessing the device or driver lists the bus maintains.

- Device and driver fields.

Some of the fields in struct device and struct device_driver duplicate fields in the bus-specific representations of these objects. Feel free to remove the bus-specific ones and favor the generic ones. Note though, that this will likely mean fixing up all the drivers that reference the bus-specific fields (though those should all be 1-line changes).

CHAPTER

TWO

DRIVER BASICS

2.1 Driver Entry and Exit points

module_init(x)
driver initialization entry point

Parameters

x function to be run at kernel boot time or module insertion

Description

`module_init()` will either be called during do_initcalls() (if builtin) or at module insertion time (if a module). There can only be one per module.

module_exit(x)
driver exit entry point

Parameters

x function to be run when driver is removed

Description

`module_exit()` will wrap the driver clean-up code with cleanup_module() when used with rmmod when the driver is a module. If the driver is statically compiled into the kernel, `module_exit()` has no effect. There can only be one per module.

2.2 Driver device table

struct **pci_device_id**
PCI device ID structure

Definition

```
struct pci_device_id {
  __u32 vendor, device;
  __u32 subvendor, subdevice;
  __u32 class, class_mask;
  kernel_ulong_t driver_data;
};
```

Members

vendor Vendor ID to match (or PCI_ANY_ID)

device Device ID to match (or PCI_ANY_ID)

subvendor Subsystem vendor ID to match (or PCI_ANY_ID)

subdevice Subsystem device ID to match (or PCI_ANY_ID)

class Device class, subclass, and "interface" to match. See Appendix D of the PCI Local Bus Spec or include/linux/pci_ids.h for a full list of classes. Most drivers do not need to specify class/class_mask as vendor/device is normally sufficient.

class_mask Limit which sub-fields of the class field are compared. See drivers/scsi/sym53c8xx_2/ for example of usage.

driver_data Data private to the driver. Most drivers don't need to use driver_data field. Best practice is to use driver_data as an index into a static list of equivalent device types, instead of using it as a pointer.

struct **usb_device_id**
identifies USB devices for probing and hotplugging

Definition

```
struct usb_device_id {
  __u16 match_flags;
  __u16 idVendor;
  __u16 idProduct;
  __u16 bcdDevice_lo;
  __u16 bcdDevice_hi;
  __u8 bDeviceClass;
  __u8 bDeviceSubClass;
  __u8 bDeviceProtocol;
  __u8 bInterfaceClass;
  __u8 bInterfaceSubClass;
  __u8 bInterfaceProtocol;
  __u8 bInterfaceNumber;
  kernel_ulong_t driver_info ;
};
```

Members

match_flags Bit mask controlling which of the other fields are used to match against new devices. Any field except for driver_info may be used, although some only make sense in conjunction with other fields. This is usually set by a USB_DEVICE_*() macro, which sets all other fields in this structure except for driver_info.

idVendor USB vendor ID for a device; numbers are assigned by the USB forum to its members.

idProduct Vendor-assigned product ID.

bcdDevice_lo Low end of range of vendor-assigned product version numbers. This is also used to identify individual product versions, for a range consisting of a single device.

bcdDevice_hi High end of version number range. The range of product versions is inclusive.

bDeviceClass Class of device; numbers are assigned by the USB forum. Products may choose to implement classes, or be vendor-specific. Device classes specify behavior of all the interfaces on a device.

bDeviceSubClass Subclass of device; associated with bDeviceClass.

bDeviceProtocol Protocol of device; associated with bDeviceClass.

bInterfaceClass Class of interface; numbers are assigned by the USB forum. Products may choose to implement classes, or be vendor-specific. Interface classes specify behavior only of a given interface; other interfaces may support other classes.

bInterfaceSubClass Subclass of interface; associated with bInterfaceClass.

bInterfaceProtocol Protocol of interface; associated with bInterfaceClass.

bInterfaceNumber Number of interface; composite devices may use fixed interface numbers to differentiate between vendor-specific interfaces.

driver_info Holds information used by the driver. Usually it holds a pointer to a descriptor understood by the driver, or perhaps device flags.

Description

In most cases, drivers will create a table of device IDs by using `USB_DEVICE()`, or similar macros designed for that purpose. They will then export it to userspace using MODULE_DEVICE_TABLE(), and provide it to the USB core through their usb_driver structure.

See the `usb_match_id()` function for information about how matches are performed. Briefly, you will normally use one of several macros to help construct these entries. Each entry you provide will either identify one or more specific products, or will identify a class of products which have agreed to behave the same. You should put the more specific matches towards the beginning of your table, so that driver_info can record quirks of specific products.

struct **mdio_device_id**
identifies PHY devices on an MDIO/MII bus

Definition

```
struct mdio_device_id {
  __u32 phy_id;
  __u32 phy_id_mask;
};
```

Members

phy_id The result of (mdio_read(`MII_PHYSID1`) << 16 | mdio_read(`MII_PHYSID2`)) & **phy_id_mask** for this PHY type

phy_id_mask Defines the significant bits of **phy_id**. A value of 0 is used to terminate an array of struct mdio_device_id.

struct **amba_id**
identifies a device on an AMBA bus

Definition

```
struct amba_id {
  unsigned int            id;
  unsigned int            mask;
  void *data;
};
```

Members

id The significant bits if the hardware device ID

mask Bitmask specifying which bits of the id field are significant when matching. A driver binds to a device when ((hardware device ID) & mask) == id.

data Private data used by the driver.

struct **mips_cdmm_device_id**
identifies devices in MIPS CDMM bus

Definition

```
struct mips_cdmm_device_id {
  __u8 type;
};
```

Members

type Device type identifier.

struct **mei_cl_device_id**
MEI client device identifier

Definition

```
struct mei_cl_device_id {
  char name[MEI_CL_NAME_SIZE];
  uuid_le uuid;
  __u8 version;
  kernel_ulong_t driver_info;
};
```

Members

name helper name

uuid client uuid

version client protocol version

driver_info information used by the driver.

Description

identifies mei client device by uuid and name

struct **rio_device_id**
RIO device identifier

Definition

```
struct rio_device_id {
  __u16 did, vid;
  __u16 asm_did, asm_vid;
};
```

Members

did RapidIO device ID

vid RapidIO vendor ID

asm_did RapidIO assembly device ID

asm_vid RapidIO assembly vendor ID

Description

Identifies a RapidIO device based on both the device/vendor IDs and the assembly device/vendor IDs.

struct **fsl_mc_device_id**
MC object device identifier

Definition

```
struct fsl_mc_device_id {
  __u16 vendor;
  const char obj_type[16];
};
```

Members

vendor vendor ID

obj_type MC object type

Description

Type of entries in the “device Id” table for MC object devices supported by a MC object device driver. The last entry of the table has vendor set to 0x0

struct **tb_service_id**
Thunderbolt service identifiers

Definition

```
struct tb_service_id {
  __u32 match_flags;
  char protocol_key[8 + 1];
  __u32 protocol_id;
  __u32 protocol_version;
  __u32 protocol_revision;
  kernel_ulong_t driver_data;
};
```

Members

match_flags Flags used to match the structure

protocol_key Protocol key the service supports

protocol_id Protocol id the service supports

protocol_version Version of the protocol

protocol_revision Revision of the protocol software

driver_data Driver specific data

Description

Thunderbolt XDomain services are exposed as devices where each device carries the protocol information the service supports. Thunderbolt XDomain service drivers match against that information.

struct **typec_device_id**
USB Type-C alternate mode identifiers

Definition

```
struct typec_device_id {
  __u16 svid;
  __u8 mode;
  kernel_ulong_t driver_data;
};
```

Members

svid Standard or Vendor ID

mode Mode index

driver_data Driver specific data

struct **tee_client_device_id**
tee based device identifier

Definition

```
struct tee_client_device_id {
  uuid_t uuid;
};
```

Members

uuid For TEE based client devices we use the device uuid as the identifier.

struct **wmi_device_id**
WMI device identifier

Definition

```
struct wmi_device_id {
  const char guid_string[UUID_STRING_LEN+1];
  const void *context;
};
```

Members

guid_string 36 char string of the form fa50ff2b-f2e8-45de-83fa-65417f2f49ba

context pointer to driver specific data

struct **mhi_device_id**
MHI device identification

Definition

```
struct mhi_device_id {
  const char chan[MHI_NAME_SIZE];
  kernel_ulong_t driver_data;
};
```

Members

chan MHI channel name

driver_data driver data;

2.3 Delaying, scheduling, and timer routines

struct **prev_cputime**
snapshot of system and user cputime

Definition

```
struct prev_cputime {
#ifndef CONFIG_VIRT_CPU_ACCOUNTING_NATIVE;
  u64 utime;
  u64 stime;
  raw_spinlock_t lock;
#endif;
};
```

Members

utime time spent in user mode

stime time spent in system mode

lock protects the above two fields

Description

Stores previous user/system time values such that we can guarantee monotonicity.

struct **util_est**
Estimation utilization of FAIR tasks

Definition

```
struct util_est {
  unsigned int                    enqueued;
  unsigned int                    ewma;
#define UTIL_EST_WEIGHT_SHIFT           2;
};
```

Members

enqueued instantaneous estimated utilization of a task/cpu

ewma the Exponential Weighted Moving Average (EWMA) utilization of a task

Description

Support data structure to track an Exponential Weighted Moving Average (EWMA) of a FAIR task's utilization. New samples are added to the moving average each time a task completes an activation. Sample's weight is chosen so that the EWMA will be relatively insensitive to transient changes to the task's workload.

The enqueued attribute has a slightly different meaning for tasks and cpus: - task: the task's util_avg at last task dequeue time - cfs_rq: the sum of util_est.enqueued for each RUNNABLE task on that CPU Thus, the util_est.enqueued of a task represents the contribution on the estimated utilization of the CPU where that task is currently enqueued.

Only for tasks we track a moving average of the past instantaneous estimated utilization. This allows to absorb sporadic drops in utilization of an otherwise almost periodic task.

int **pid_alive**(const struct task_struct * p)
check that a task structure is not stale

Parameters

const struct task_struct * p Task structure to be checked.

Description

Test if a process is not yet dead (at most zombie state) If pid_alive fails, then pointers within the task structure can be stale and must not be dereferenced.

Return

1 if the process is alive. 0 otherwise.

int **is_global_init**(struct task_struct * tsk)
check if a task structure is init. Since init is free to have sub-threads we need to check tgid.

Parameters

struct task_struct * tsk Task structure to be checked.

Description

Check if a task structure is the first user space task the kernel created.

Return

1 if the task structure is init. 0 otherwise.

int **task_nice**(const struct task_struct * p)
return the nice value of a given task.

Parameters

const struct task_struct * p the task in question.

Return

The nice value [-20 ⋯0 ⋯19].

bool **is_idle_task**(const struct task_struct * p)
is the specified task an idle task?

Parameters

const struct task_struct * p the task in question.

Return

1 if **p** is an idle task. 0 otherwise.

int **wake_up_process**(struct task_struct * p)
Wake up a specific process

Parameters

struct task_struct * p The process to be woken up.

Description

Attempt to wake up the nominated process and move it to the set of runnable processes.

This function executes a full memory barrier before accessing the task state.

Return

1 if the process was woken up, 0 if it was already running.

void **preempt_notifier_register**(struct preempt_notifier * notifier)
tell me when current is being preempted & rescheduled

Parameters

struct preempt_notifier * notifier notifier struct to register

void **preempt_notifier_unregister**(struct preempt_notifier * notifier)
no longer interested in preemption notifications

Parameters

struct preempt_notifier * notifier notifier struct to unregister

Description

This is not safe to call from within a preemption notifier.

__visible void notrace **preempt_schedule_notrace**(void)
preempt_schedule called by tracing

Parameters

void no arguments

Description

The tracing infrastructure uses preempt_enable_notrace to prevent recursion and tracing preempt enabling caused by the tracing infrastructure itself. But as tracing can happen in areas coming from userspace or just about to enter userspace, a preempt enable can occur before user_exit() is called. This will cause the scheduler to be called when the system is still in usermode.

To prevent this, the preempt_enable_notrace will use this function instead of preempt_schedule() to exit user context if needed before calling the scheduler.

int **sched_setscheduler**(struct task_struct * p, int policy, const struct sched_param * param)
change the scheduling policy and/or RT priority of a thread.

Parameters

struct task_struct * p the task in question.

int policy new policy.

const struct sched_param * param structure containing the new RT priority.

Return

0 on success. An error code otherwise.

Description

NOTE that the task may be already dead.

int **sched_setscheduler_nocheck**(struct task_struct * p, int policy, const struct sched_param * param)
change the scheduling policy and/or RT priority of a thread from kernelspace.

Parameters

struct task_struct * p the task in question.

int policy new policy.

const struct sched_param * param structure containing the new RT priority.

Description

Just like sched_setscheduler, only don't bother checking if the current context has permission. For example, this is needed in stop_machine(): we create temporary high priority worker threads, but our caller might not have that capability.

Return

0 on success. An error code otherwise.

void **yield**(void)
yield the current processor to other threads.

Parameters

void no arguments

Description

Do not ever use this function, there's a 99% chance you're doing it wrong.

The scheduler is at all times free to pick the calling task as the most eligible task to run, if removing the `yield()` call from your code breaks it, its already broken.

Typical broken usage is:

while (!event) `yield();`

where one assumes that `yield()` will let 'the other' process run that will make event true. If the current task is a SCHED_FIFO task that will never happen. Never use `yield()` as a progress guarantee!!

If you want to use `yield()` to wait for something, use `wait_event()`. If you want to use `yield()` to be 'nice' for others, use cond_resched(). If you still want to use `yield()`, do not!

int **yield_to**(struct task_struct * p, bool preempt)
yield the current processor to another thread in your thread group, or accelerate that thread toward the processor it's on.

Parameters

struct task_struct * p target task

bool preempt whether task preemption is allowed or not

Description

It's the caller's job to ensure that the target task struct can't go away on us before we can do any checks.

Return

true (>0) if we indeed boosted the target task. false (0) if we failed to boost the target. -ESRCH if there's no task to yield to.

int **cpupri_find_fitness**(struct cpupri * cp, struct task_struct * p, struct cpumask * lowest_mask, bool (*fitness_fn)(struct task_struct *p, int cpu))
find the best (lowest-pri) CPU in the system

Parameters

struct cpupri * cp The cpupri context

struct task_struct * p The task

struct cpumask * lowest_mask A mask to fill in with selected CPUs (or NULL)

bool (*)(struct task_struct *p, int cpu) fitness_fn A pointer to a function to do custom checks whether the CPU fits a specific criteria so that we only return those CPUs.

Note

This function returns the recommended CPUs as calculated during the current invocation. By the time the call returns, the CPUs may have in fact changed priorities any number of times. While not ideal, it is not an issue of correctness since the normal rebalancer logic will correct any discrepancies created by racing against the uncertainty of the current priority configuration.

Return

(int)bool - CPUs were found

void **cpupri_set**(struct cpupri * cp, int cpu, int newpri)
update the CPU priority setting

Parameters

struct cpupri * cp The cpupri context

int cpu The target CPU

int newpri The priority (INVALID-RT99) to assign to this CPU

Note

Assumes cpu_rq(cpu)->lock is locked

Return

(void)

int **cpupri_init**(struct cpupri * cp)
initialize the cpupri structure

Parameters

struct cpupri * cp The cpupri context

Return

-ENOMEM on memory allocation failure.

void **cpupri_cleanup**(struct cpupri * cp)
clean up the cpupri structure

Parameters

struct cpupri * cp The cpupri context

void **update_tg_load_avg**(struct cfs_rq * cfs_rq, int force)
update the tg's load avg

Parameters

struct cfs_rq * cfs_rq the cfs_rq whose avg changed

int force update regardless of how small the difference

Description

This function 'ensures': tg->load_avg := Sum tg->cfs_rq[]->avg.load. However, because tg->load_avg is a global value there are performance considerations.

In order to avoid having to look at the other cfs_rq's, we use a differential update where we store the last value we propagated. This in turn allows skipping updates if the differential is 'small'.

Updating tg's load_avg is necessary before update_cfs_share().

int **update_cfs_rq_load_avg**(u64 now, struct cfs_rq * cfs_rq)
update the cfs_rq's load/util averages

Parameters

u64 now current time, as per cfs_rq_clock_pelt()

struct cfs_rq * cfs_rq cfs_rq to update

Description

The cfs_rq avg is the direct sum of all its entities (blocked and runnable) avg. The immediate corollary is that all (fair) tasks must be attached, see post_init_entity_util_avg().

cfs_rq->avg is used for task_h_load() and update_cfs_share() for example.

Returns true if the load decayed or we removed load.

Since both these conditions indicate a changed cfs_rq->avg.load we should call `update_tg_load_avg()` when this function returns true.

void **attach_entity_load_avg**(struct cfs_rq * cfs_rq, struct sched_entity * se)

attach this entity to its cfs_rq load avg

Parameters

struct cfs_rq * cfs_rq cfs_rq to attach to

struct sched_entity * se sched_entity to attach

Description

Must call `update_cfs_rq_load_avg()` before this, since we rely on cfs_rq->avg.last_update_time being current.

void **detach_entity_load_avg**(struct cfs_rq * cfs_rq, struct sched_entity * se)

detach this entity from its cfs_rq load avg

Parameters

struct cfs_rq * cfs_rq cfs_rq to detach from

struct sched_entity * se sched_entity to detach

Description

Must call `update_cfs_rq_load_avg()` before this, since we rely on cfs_rq->avg.last_update_time being current.

unsigned long **cpu_util**(int cpu)

Parameters

int cpu the CPU to get the utilization of

Description

The unit of the return value must be the one of capacity so we can compare the utilization with the capacity of the CPU that is available for CFS task (ie cpu_capacity).

cfs_rq.avg.util_avg is the sum of running time of runnable tasks plus the recent utilization of currently non-runnable tasks on a CPU. It represents the amount of utilization of a CPU in the range [0..capacity_orig] where capacity_orig is the cpu_capacity available at the highest frequency (arch_scale_freq_capacity()). The utilization of a CPU converges towards a sum equal to or less than the current capacity (capacity_curr <= capacity_orig) of the CPU because it is the running time on this CPU scaled by capacity_curr.

The estimated utilization of a CPU is defined to be the maximum between its cfs_rq.avg.util_avg and the sum of the estimated utilization of the tasks currently RUNNABLE on that CPU. This allows to properly represent the expected utilization of a CPU which has just got a big task running since a long sleep period. At the same time however it preserves the benefits of the “blocked utilization” in describing the potential for other tasks waking up on the same CPU.

Nevertheless, cfs_rq.avg.util_avg can be higher than capacity_curr or even higher than capacity_orig because of unfortunate rounding in cfs.avg.util_avg or just after migrating tasks and new task wakeups until the average stabilizes with the new running time. We need to check that the utilization stays within the range of [0..capacity_orig] and cap it if necessary. Without utilization capping, a group could be seen as overloaded (CPU0 utilization at 121% + CPU1 utilization at 80%) whereas CPU1 has 20% of available capacity. We allow utilization to overshoot capacity_curr (but not capacity_orig) as it useful for predicting the capacity required after task migrations (scheduler-driven DVFS).

Return

the (estimated) utilization for the specified CPU

void **update_sg_lb_stats**(struct lb_env * env, struct sched_group * group, struct sg_lb_stats * sgs, int * sg_status)
Update sched_group's statistics for load balancing.

Parameters

struct lb_env * env The load balancing environment.

struct sched_group * group sched_group whose statistics are to be updated.

struct sg_lb_stats * sgs variable to hold the statistics for this group.

int * sg_status Holds flag indicating the status of the sched_group

bool **update_sd_pick_busiest**(struct lb_env * env, struct sd_lb_stats * sds, struct sched_group * sg, struct sg_lb_stats * sgs)
return 1 on busiest group

Parameters

struct lb_env * env The load balancing environment.

struct sd_lb_stats * sds sched_domain statistics

struct sched_group * sg sched_group candidate to be checked for being the busiest

struct sg_lb_stats * sgs sched_group statistics

Description

Determine if **sg** is a busier group than the previously selected busiest group.

Return

`true` if **sg** is a busier group than the previously selected busiest group. `false` otherwise.

int **idle_cpu_without**(int cpu, struct task_struct * p)
would a given CPU be idle without p ?

Parameters

int cpu the processor on which idleness is tested.

struct task_struct * p task which should be ignored.

Return

1 if the CPU would be idle. 0 otherwise.

void **update_sd_lb_stats**(struct lb_env * env, struct sd_lb_stats * sds)
Update sched_domain’s statistics for load balancing.

Parameters

struct lb_env * env The load balancing environment.

struct sd_lb_stats * sds variable to hold the statistics for this sched_domain.

void **calculate_imbalance**(struct lb_env * env, struct sd_lb_stats * sds)
Calculate the amount of imbalance present within the groups of a given sched_domain during load balance.

Parameters

struct lb_env * env load balance environment

struct sd_lb_stats * sds statistics of the sched_domain whose imbalance is to be calculated.

struct sched_group * **find_busiest_group**(struct lb_env * env)
Returns the busiest group within the sched_domain if there is an imbalance.

Parameters

struct lb_env * env The load balancing environment.

Description

Also calculates the amount of runnable load which should be moved to restore balance.

Return

- The busiest group if imbalance exists.

DECLARE_COMPLETION(work)
declare and initialize a completion structure

Parameters

work identifier for the completion structure

Description

This macro declares and initializes a completion structure. Generally used for static declarations. You should use the _ONSTACK variant for automatic variables.

DECLARE_COMPLETION_ONSTACK(work)
declare and initialize a completion structure

Parameters

work identifier for the completion structure

Description

This macro declares and initializes a completion structure on the kernel stack.

void **__init_completion**(struct completion * x)
Initialize a dynamically allocated completion

Parameters

struct completion * x pointer to completion structure that is to be initialized

Description

This inline function will initialize a dynamically created completion structure.

void **reinit_completion**(struct completion * x)
reinitialize a completion structure

Parameters

struct completion * x pointer to completion structure that is to be reinitialized

Description

This inline function should be used to reinitialize a completion structure so it can be reused. This is especially important after complete_all() is used.

unsigned long **__round_jiffies**(unsigned long j, int cpu)
function to round jiffies to a full second

Parameters

unsigned long j the time in (absolute) jiffies that should be rounded

int cpu the processor number on which the timeout will happen

Description

`__round_jiffies()` rounds an absolute time in the future (in jiffies) up or down to (approximately) full seconds. This is useful for timers for which the exact time they fire does not matter too much, as long as they fire approximately every X seconds.

By rounding these timers to whole seconds, all such timers will fire at the same time, rather than at various times spread out. The goal of this is to have the CPU wake up less, which saves power.

The exact rounding is skewed for each processor to avoid all processors firing at the exact same time, which could lead to lock contention or spurious cache line bouncing.

The return value is the rounded version of the **j** parameter.

unsigned long **__round_jiffies_relative**(unsigned long j, int cpu)
function to round jiffies to a full second

Parameters

unsigned long j the time in (relative) jiffies that should be rounded

int cpu the processor number on which the timeout will happen

Description

`__round_jiffies_relative()` rounds a time delta in the future (in jiffies) up or down to (approximately) full seconds. This is useful for timers for which the exact

time they fire does not matter too much, as long as they fire approximately every X seconds.

By rounding these timers to whole seconds, all such timers will fire at the same time, rather than at various times spread out. The goal of this is to have the CPU wake up less, which saves power.

The exact rounding is skewed for each processor to avoid all processors firing at the exact same time, which could lead to lock contention or spurious cache line bouncing.

The return value is the rounded version of the **j** parameter.

unsigned long **round_jiffies**(unsigned long j)
function to round jiffies to a full second

Parameters

unsigned long j the time in (absolute) jiffies that should be rounded

Description

round_jiffies() rounds an absolute time in the future (in jiffies) up or down to (approximately) full seconds. This is useful for timers for which the exact time they fire does not matter too much, as long as they fire approximately every X seconds.

By rounding these timers to whole seconds, all such timers will fire at the same time, rather than at various times spread out. The goal of this is to have the CPU wake up less, which saves power.

The return value is the rounded version of the **j** parameter.

unsigned long **round_jiffies_relative**(unsigned long j)
function to round jiffies to a full second

Parameters

unsigned long j the time in (relative) jiffies that should be rounded

Description

round_jiffies_relative() rounds a time delta in the future (in jiffies) up or down to (approximately) full seconds. This is useful for timers for which the exact time they fire does not matter too much, as long as they fire approximately every X seconds.

By rounding these timers to whole seconds, all such timers will fire at the same time, rather than at various times spread out. The goal of this is to have the CPU wake up less, which saves power.

The return value is the rounded version of the **j** parameter.

unsigned long **__round_jiffies_up**(unsigned long j, int cpu)
function to round jiffies up to a full second

Parameters

unsigned long j the time in (absolute) jiffies that should be rounded

int cpu the processor number on which the timeout will happen

Description

This is the same as `__round_jiffies()` except that it will never round down. This is useful for timeouts for which the exact time of firing does not matter too much, as long as they don't fire too early.

unsigned long **__round_jiffies_up_relative**(unsigned long j, int cpu)
function to round jiffies up to a full second

Parameters

unsigned long j the time in (relative) jiffies that should be rounded

int cpu the processor number on which the timeout will happen

Description

This is the same as `__round_jiffies_relative()` except that it will never round down. This is useful for timeouts for which the exact time of firing does not matter too much, as long as they don't fire too early.

unsigned long **round_jiffies_up**(unsigned long j)
function to round jiffies up to a full second

Parameters

unsigned long j the time in (absolute) jiffies that should be rounded

Description

This is the same as `round_jiffies()` except that it will never round down. This is useful for timeouts for which the exact time of firing does not matter too much, as long as they don't fire too early.

unsigned long **round_jiffies_up_relative**(unsigned long j)
function to round jiffies up to a full second

Parameters

unsigned long j the time in (relative) jiffies that should be rounded

Description

This is the same as `round_jiffies_relative()` except that it will never round down. This is useful for timeouts for which the exact time of firing does not matter too much, as long as they don't fire too early.

void **init_timer_key**(struct timer_list * timer, void (*func)(struct timer_list *), unsigned int flags, const char * name, struct lock_class_key * key)
initialize a timer

Parameters

struct timer_list * timer the timer to be initialized

void (*)(struct timer_list *) func timer callback function

unsigned int flags timer flags

const char * name name of the timer

struct lock_class_key * key lockdep class key of the fake lock used for tracking timer sync lock dependencies

Description

`init_timer_key()` must be done to a timer prior calling any of the other timer functions.

int **mod_timer_pending**(struct timer_list * timer, unsigned long expires)
modify a pending timer's timeout

Parameters

struct timer_list * timer the pending timer to be modified

unsigned long expires new timeout in jiffies

Description

`mod_timer_pending()` is the same for pending timers as `mod_timer()`, but will not re-activate and modify already deleted timers.

It is useful for unserialized use of timers.

int **mod_timer**(struct timer_list * timer, unsigned long expires)
modify a timer's timeout

Parameters

struct timer_list * timer the timer to be modified

unsigned long expires new timeout in jiffies

Description

`mod_timer()` is a more efficient way to update the expire field of an active timer (if the timer is inactive it will be activated)

mod_timer(timer, expires) is equivalent to:

del_timer(timer); timer->expires = expires; add_timer(timer);

Note that if there are multiple unserialized concurrent users of the same timer, then `mod_timer()` is the only safe way to modify the timeout, since `add_timer()` cannot modify an already running timer.

The function returns whether it has modified a pending timer or not. (ie. `mod_timer()` of an inactive timer returns 0, `mod_timer()` of an active timer returns 1.)

int **timer_reduce**(struct timer_list * timer, unsigned long expires)
Modify a timer's timeout if it would reduce the timeout

Parameters

struct timer_list * timer The timer to be modified

unsigned long expires New timeout in jiffies

Description

`timer_reduce()` is very similar to `mod_timer()`, except that it will only modify a running timer if that would reduce the expiration time (it will start a timer that isn't running).

void **add_timer**(struct timer_list * timer)
start a timer

Parameters

struct timer_list * timer the timer to be added

Description

The kernel will do a ->function(**timer**) callback from the timer interrupt at the ->expires point in the future. The current time is 'jiffies'.

The timer's ->expires, ->function fields must be set prior calling this function.

Timers with an ->expires field in the past will be executed in the next timer tick.

void **add_timer_on**(struct timer_list * timer, int cpu)
start a timer on a particular CPU

Parameters

struct timer_list * timer the timer to be added

int cpu the CPU to start it on

Description

This is not very scalable on SMP. Double adds are not possible.

int **del_timer**(struct timer_list * timer)
deactivate a timer.

Parameters

struct timer_list * timer the timer to be deactivated

Description

`del_timer()` deactivates a timer - this works on both active and inactive timers.

The function returns whether it has deactivated a pending timer or not. (ie. `del_timer()` of an inactive timer returns 0, `del_timer()` of an active timer returns 1.)

int **try_to_del_timer_sync**(struct timer_list * timer)
Try to deactivate a timer

Parameters

struct timer_list * timer timer to delete

Description

This function tries to deactivate a timer. Upon successful (ret >= 0) exit the timer is not queued and the handler is not running on any CPU.

int **del_timer_sync**(struct timer_list * timer)
deactivate a timer and wait for the handler to finish.

Parameters

struct timer_list * timer the timer to be deactivated

Description

This function only differs from `del_timer()` on SMP: besides deactivating the timer it also makes sure the handler has finished executing on other CPUs.

Synchronization rules: Callers must prevent restarting of the timer, otherwise this function is meaningless. It must not be called from interrupt contexts unless the timer is an irqsafe one. The caller must not hold locks which would prevent completion of the timer's handler. The timer's handler must not call `add_timer_on()`. Upon exit the timer is not queued and the handler is not running on any CPU.

Now `del_timer_sync()` will never return and never release somelock. The interrupt on the other CPU is waiting to grab somelock but it has interrupted the softirq that CPU0 is waiting to finish.

The function returns whether it has deactivated a pending timer or not.

Note

For !irqsafe timers, you must not hold locks that are held in interrupt context while calling this function. Even if the lock has nothing to do with the timer in question. Here's why:

```
CPU0                                CPU1
----                                ----
                                    <SOFTIRQ>
                                      call_timer_fn();
                                      base->running_timer = mytimer;
spin_lock_irq(somelock);
                                    <IRQ>
                                       spin_lock(somelock);
del_timer_sync(mytimer);
while (base->running_timer == mytimer);
```

signed long **schedule_timeout**(signed long timeout)
sleep until timeout

Parameters

signed long timeout timeout value in jiffies

Description

Make the current task sleep until **timeout** jiffies have elapsed. The function behavior depends on the current task state (see also set_current_state() description):

`TASK_RUNNING` - the scheduler is called, but the task does not sleep at all. That happens because sched_submit_work() does nothing for tasks in `TASK_RUNNING` state.

`TASK_UNINTERRUPTIBLE` - at least **timeout** jiffies are guaranteed to pass before the routine returns unless the current task is explicitly woken up, (e.g. by `wake_up_process()`).

`TASK_INTERRUPTIBLE` - the routine may return early if a signal is delivered to the current task or the current task is explicitly woken up.

The current task state is guaranteed to be `TASK_RUNNING` when this routine returns.

Specifying a **timeout** value of MAX_SCHEDULE_TIMEOUT will schedule the CPU away without a bound on the timeout. In this case the return value will be MAX_SCHEDULE_TIMEOUT.

Returns 0 when the timer has expired otherwise the remaining time in jiffies will be returned. In all cases the return value is guaranteed to be non-negative.

void **msleep**(unsigned int msecs)
sleep safely even with waitqueue interruptions

Parameters

unsigned int msecs Time in milliseconds to sleep for

unsigned long **msleep_interruptible**(unsigned int msecs)
sleep waiting for signals

Parameters

unsigned int msecs Time in milliseconds to sleep for

void **usleep_range**(unsigned long min, unsigned long max)
Sleep for an approximate time

Parameters

unsigned long min Minimum time in usecs to sleep

unsigned long max Maximum time in usecs to sleep

Description

In non-atomic context where the exact wakeup time is flexible, use usleep_range() instead of udelay(). The sleep improves responsiveness by avoiding the CPU-hogging busy-wait of udelay(), and the range reduces power usage by allowing hrtimers to take advantage of an already- scheduled interrupt instead of scheduling a new one just for this sleep.

2.4 Wait queues and Wake events

int **waitqueue_active**(struct wait_queue_head * wq_head)

- locklessly test for waiters on the queue

Parameters

struct wait_queue_head * wq_head the waitqueue to test for waiters

Description

returns true if the wait list is not empty

Use either while holding wait_queue_head::lock or when used for wakeups with an extra smp_mb() like:

```
CPU0 - waker                    CPU1 - waiter

                                for (;;) {
@cond = true;                     prepare_to_wait(&wq_head, &wait, state);
```

(continues on next page)

(continued from previous page)

```
smp_mb();                           // smp_mb() from set_current_state()
if (waitqueue_active(wq_head))           if (@cond)
  wake_up(wq_head);                        break;
                                    schedule();
                                  }
                                  finish_wait(&wq_head, &wait);
```

Because without the explicit smp_mb() it's possible for the `waitqueue_active()` load to get hoisted over the **cond** store such that we'll observe an empty wait list while the waiter might not observe **cond**.

Also note that this 'optimization' trades a spin_lock() for an smp_mb(), which (when the lock is uncontended) are of roughly equal cost.

NOTE

this function is lockless and requires care, incorrect usage _will_ lead to sporadic and non-obvious failure.

bool **wq_has_single_sleeper**(struct wait_queue_head * wq_head)
check if there is only one sleeper

Parameters

struct wait_queue_head * wq_head wait queue head

Description

Returns true of wq_head has only one sleeper on the list.

Please refer to the comment for waitqueue_active.

bool **wq_has_sleeper**(struct wait_queue_head * wq_head)
check if there are any waiting processes

Parameters

struct wait_queue_head * wq_head wait queue head

Description

Returns true if wq_head has waiting processes

Please refer to the comment for waitqueue_active.

wait_event(wq_head, condition)
sleep until a condition gets true

Parameters

wq_head the waitqueue to wait on

condition a C expression for the event to wait for

Description

The process is put to sleep (TASK_UNINTERRUPTIBLE) until the **condition** evaluates to true. The **condition** is checked each time the waitqueue **wq_head** is woken up.

wake_up() has to be called after changing any variable that could change the result of the wait condition.

wait_event_freezable(wq_head, condition)
sleep (or freeze) until a condition gets true

Parameters

wq_head the waitqueue to wait on

condition a C expression for the event to wait for

Description

The process is put to sleep (TASK_INTERRUPTIBLE – so as not to contribute to system load) until the **condition** evaluates to true. The **condition** is checked each time the waitqueue **wq_head** is woken up.

wake_up() has to be called after changing any variable that could change the result of the wait condition.

wait_event_timeout(wq_head, condition, timeout)
sleep until a condition gets true or a timeout elapses

Parameters

wq_head the waitqueue to wait on

condition a C expression for the event to wait for

timeout timeout, in jiffies

Description

The process is put to sleep (TASK_UNINTERRUPTIBLE) until the **condition** evaluates to true. The **condition** is checked each time the waitqueue **wq_head** is woken up.

wake_up() has to be called after changing any variable that could change the result of the wait condition.

Return

0 if the **condition** evaluated to `false` after the **timeout** elapsed, 1 if the **condition** evaluated to `true` after the **timeout** elapsed, or the remaining jiffies (at least 1) if the **condition** evaluated to `true` before the **timeout** elapsed.

wait_event_cmd(wq_head, condition, cmd1, cmd2)
sleep until a condition gets true

Parameters

wq_head the waitqueue to wait on

condition a C expression for the event to wait for

cmd1 the command will be executed before sleep

cmd2 the command will be executed after sleep

Description

The process is put to sleep (TASK_UNINTERRUPTIBLE) until the **condition** evaluates to true. The **condition** is checked each time the waitqueue **wq_head** is woken up.

wake_up() has to be called after changing any variable that could change the result of the wait condition.

wait_event_interruptible(wq_head, condition)
sleep until a condition gets true

Parameters

wq_head the waitqueue to wait on

condition a C expression for the event to wait for

Description

The process is put to sleep (TASK_INTERRUPTIBLE) until the **condition** evaluates to true or a signal is received. The **condition** is checked each time the waitqueue **wq_head** is woken up.

wake_up() has to be called after changing any variable that could change the result of the wait condition.

The function will return -ERESTARTSYS if it was interrupted by a signal and 0 if **condition** evaluated to true.

wait_event_interruptible_timeout(wq_head, condition, timeout)
sleep until a condition gets true or a timeout elapses

Parameters

wq_head the waitqueue to wait on

condition a C expression for the event to wait for

timeout timeout, in jiffies

Description

The process is put to sleep (TASK_INTERRUPTIBLE) until the **condition** evaluates to true or a signal is received. The **condition** is checked each time the waitqueue **wq_head** is woken up.

wake_up() has to be called after changing any variable that could change the result of the wait condition.

Return

0 if the **condition** evaluated to `false` after the **timeout** elapsed, 1 if the **condition** evaluated to `true` after the **timeout** elapsed, the remaining jiffies (at least 1) if the **condition** evaluated to `true` before the **timeout** elapsed, or -ERESTARTSYS if it was interrupted by a signal.

wait_event_hrtimeout(wq_head, condition, timeout)
sleep until a condition gets true or a timeout elapses

Parameters

wq_head the waitqueue to wait on

condition a C expression for the event to wait for

timeout timeout, as a ktime_t

Description

The process is put to sleep (TASK_UNINTERRUPTIBLE) until the **condition** evaluates to true or a signal is received. The **condition** is checked each time the waitqueue **wq_head** is woken up.

wake_up() has to be called after changing any variable that could change the result of the wait condition.

The function returns 0 if **condition** became true, or -ETIME if the timeout elapsed.

wait_event_interruptible_hrtimeout(wq, condition, timeout)
sleep until a condition gets true or a timeout elapses

Parameters

wq the waitqueue to wait on

condition a C expression for the event to wait for

timeout timeout, as a ktime_t

Description

The process is put to sleep (TASK_INTERRUPTIBLE) until the **condition** evaluates to true or a signal is received. The **condition** is checked each time the waitqueue **wq** is woken up.

wake_up() has to be called after changing any variable that could change the result of the wait condition.

The function returns 0 if **condition** became true, -ERESTARTSYS if it was interrupted by a signal, or -ETIME if the timeout elapsed.

wait_event_idle(wq_head, condition)
wait for a condition without contributing to system load

Parameters

wq_head the waitqueue to wait on

condition a C expression for the event to wait for

Description

The process is put to sleep (TASK_IDLE) until the **condition** evaluates to true. The **condition** is checked each time the waitqueue **wq_head** is woken up.

wake_up() has to be called after changing any variable that could change the result of the wait condition.

wait_event_idle_exclusive(wq_head, condition)
wait for a condition with contributing to system load

Parameters

wq_head the waitqueue to wait on

condition a C expression for the event to wait for

Description

The process is put to sleep (TASK_IDLE) until the **condition** evaluates to true. The **condition** is checked each time the waitqueue **wq_head** is woken up.

The process is put on the wait queue with an WQ_FLAG_EXCLUSIVE flag set thus if other processes wait on the same list, when this process is woken further processes are not considered.

wake_up() has to be called after changing any variable that could change the result of the wait condition.

wait_event_idle_timeout(wq_head, condition, timeout)
sleep without load until a condition becomes true or a timeout elapses

Parameters

wq_head the waitqueue to wait on

condition a C expression for the event to wait for

timeout timeout, in jiffies

Description

The process is put to sleep (TASK_IDLE) until the **condition** evaluates to true. The **condition** is checked each time the waitqueue **wq_head** is woken up.

wake_up() has to be called after changing any variable that could change the result of the wait condition.

Return

0 if the **condition** evaluated to `false` after the **timeout** elapsed, 1 if the **condition** evaluated to `true` after the **timeout** elapsed, or the remaining jiffies (at least 1) if the **condition** evaluated to `true` before the **timeout** elapsed.

wait_event_idle_exclusive_timeout(wq_head, condition, timeout)
sleep without load until a condition becomes true or a timeout elapses

Parameters

wq_head the waitqueue to wait on

condition a C expression for the event to wait for

timeout timeout, in jiffies

Description

The process is put to sleep (TASK_IDLE) until the **condition** evaluates to true. The **condition** is checked each time the waitqueue **wq_head** is woken up.

The process is put on the wait queue with an WQ_FLAG_EXCLUSIVE flag set thus if other processes wait on the same list, when this process is woken further processes are not considered.

wake_up() has to be called after changing any variable that could change the result of the wait condition.

Return

0 if the **condition** evaluated to `false` after the **timeout** elapsed, 1 if the **condition** evaluated to `true` after the **timeout** elapsed, or the remaining jiffies (at least 1) if the **condition** evaluated to `true` before the **timeout** elapsed.

wait_event_interruptible_locked(wq, condition)
sleep until a condition gets true

Parameters

wq the waitqueue to wait on

condition a C expression for the event to wait for

Description

The process is put to sleep (TASK_INTERRUPTIBLE) until the **condition** evaluates to true or a signal is received. The **condition** is checked each time the waitqueue **wq** is woken up.

It must be called with wq.lock being held. This spinlock is unlocked while sleeping but **condition** testing is done while lock is held and when this macro exits the lock is held.

The lock is locked/unlocked using spin_lock()/spin_unlock() functions which must match the way they are locked/unlocked outside of this macro.

wake_up_locked() has to be called after changing any variable that could change the result of the wait condition.

The function will return -ERESTARTSYS if it was interrupted by a signal and 0 if **condition** evaluated to true.

wait_event_interruptible_locked_irq(wq, condition)
sleep until a condition gets true

Parameters

wq the waitqueue to wait on

condition a C expression for the event to wait for

Description

The process is put to sleep (TASK_INTERRUPTIBLE) until the **condition** evaluates to true or a signal is received. The **condition** is checked each time the waitqueue **wq** is woken up.

It must be called with wq.lock being held. This spinlock is unlocked while sleeping but **condition** testing is done while lock is held and when this macro exits the lock is held.

The lock is locked/unlocked using spin_lock_irq()/spin_unlock_irq() functions which must match the way they are locked/unlocked outside of this macro.

wake_up_locked() has to be called after changing any variable that could change the result of the wait condition.

The function will return -ERESTARTSYS if it was interrupted by a signal and 0 if **condition** evaluated to true.

wait_event_interruptible_exclusive_locked(wq, condition)
sleep exclusively until a condition gets true

Parameters

wq the waitqueue to wait on

condition a C expression for the event to wait for

Description

The process is put to sleep (TASK_INTERRUPTIBLE) until the **condition** evaluates to true or a signal is received. The **condition** is checked each time the waitqueue **wq** is woken up.

It must be called with wq.lock being held. This spinlock is unlocked while sleeping but **condition** testing is done while lock is held and when this macro exits the lock is held.

The lock is locked/unlocked using spin_lock()/spin_unlock() functions which must match the way they are locked/unlocked outside of this macro.

The process is put on the wait queue with an WQ_FLAG_EXCLUSIVE flag set thus when other process waits process on the list if this process is awaken further processes are not considered.

wake_up_locked() has to be called after changing any variable that could change the result of the wait condition.

The function will return -ERESTARTSYS if it was interrupted by a signal and 0 if **condition** evaluated to true.

wait_event_interruptible_exclusive_locked_irq(wq, condition)
sleep until a condition gets true

Parameters

wq the waitqueue to wait on

condition a C expression for the event to wait for

Description

The process is put to sleep (TASK_INTERRUPTIBLE) until the **condition** evaluates to true or a signal is received. The **condition** is checked each time the waitqueue **wq** is woken up.

It must be called with wq.lock being held. This spinlock is unlocked while sleeping but **condition** testing is done while lock is held and when this macro exits the lock is held.

The lock is locked/unlocked using spin_lock_irq()/spin_unlock_irq() functions which must match the way they are locked/unlocked outside of this macro.

The process is put on the wait queue with an WQ_FLAG_EXCLUSIVE flag set thus when other process waits process on the list if this process is awaken further processes are not considered.

wake_up_locked() has to be called after changing any variable that could change the result of the wait condition.

The function will return -ERESTARTSYS if it was interrupted by a signal and 0 if **condition** evaluated to true.

wait_event_killable(wq_head, condition)
sleep until a condition gets true

Parameters

wq_head the waitqueue to wait on

condition a C expression for the event to wait for

Description

The process is put to sleep (TASK_KILLABLE) until the **condition** evaluates to true or a signal is received. The **condition** is checked each time the waitqueue **wq_head** is woken up.

wake_up() has to be called after changing any variable that could change the result of the wait condition.

The function will return -ERESTARTSYS if it was interrupted by a signal and 0 if **condition** evaluated to true.

wait_event_killable_timeout(wq_head, condition, timeout)
sleep until a condition gets true or a timeout elapses

Parameters

wq_head the waitqueue to wait on

condition a C expression for the event to wait for

timeout timeout, in jiffies

Description

The process is put to sleep (TASK_KILLABLE) until the **condition** evaluates to true or a kill signal is received. The **condition** is checked each time the waitqueue **wq_head** is woken up.

wake_up() has to be called after changing any variable that could change the result of the wait condition.

Only kill signals interrupt this process.

Return

0 if the **condition** evaluated to `false` after the **timeout** elapsed, 1 if the **condition** evaluated to `true` after the **timeout** elapsed, the remaining jiffies (at least 1) if the **condition** evaluated to `true` before the **timeout** elapsed, or `-ERESTARTSYS` if it was interrupted by a kill signal.

wait_event_lock_irq_cmd(wq_head, condition, lock, cmd)
sleep until a condition gets true. The condition is checked under the lock. This is expected to be called with the lock taken.

Parameters

wq_head the waitqueue to wait on

condition a C expression for the event to wait for

lock a locked spinlock_t, which will be released before cmd and schedule() and reacquired afterwards.

cmd a command which is invoked outside the critical section before sleep

Description

The process is put to sleep (TASK_UNINTERRUPTIBLE) until the **condition** evaluates to true. The **condition** is checked each time the waitqueue **wq_head** is woken up.

wake_up() has to be called after changing any variable that could change the result of the wait condition.

This is supposed to be called while holding the lock. The lock is dropped before invoking the cmd and going to sleep and is reacquired afterwards.

wait_event_lock_irq(wq_head, condition, lock)
sleep until a condition gets true. The condition is checked under the lock. This is expected to be called with the lock taken.

Parameters

wq_head the waitqueue to wait on

condition a C expression for the event to wait for

lock a locked spinlock_t, which will be released before schedule() and reacquired afterwards.

Description

The process is put to sleep (TASK_UNINTERRUPTIBLE) until the **condition** evaluates to true. The **condition** is checked each time the waitqueue **wq_head** is woken up.

wake_up() has to be called after changing any variable that could change the result of the wait condition.

This is supposed to be called while holding the lock. The lock is dropped before going to sleep and is reacquired afterwards.

wait_event_interruptible_lock_irq_cmd(wq_head, condition, lock, cmd)
sleep until a condition gets true. The condition is checked under the lock. This is expected to be called with the lock taken.

Parameters

wq_head the waitqueue to wait on

condition a C expression for the event to wait for

lock a locked spinlock_t, which will be released before cmd and schedule() and reacquired afterwards.

cmd a command which is invoked outside the critical section before sleep

Description

The process is put to sleep (TASK_INTERRUPTIBLE) until the **condition** evaluates to true or a signal is received. The **condition** is checked each time the waitqueue **wq_head** is woken up.

wake_up() has to be called after changing any variable that could change the result of the wait condition.

This is supposed to be called while holding the lock. The lock is dropped before invoking the cmd and going to sleep and is reacquired afterwards.

The macro will return -ERESTARTSYS if it was interrupted by a signal and 0 if **condition** evaluated to true.

wait_event_interruptible_lock_irq(wq_head, condition, lock)
sleep until a condition gets true. The condition is checked under the lock. This is expected to be called with the lock taken.

Parameters

wq_head the waitqueue to wait on

condition a C expression for the event to wait for

lock a locked spinlock_t, which will be released before schedule() and reacquired afterwards.

Description

The process is put to sleep (TASK_INTERRUPTIBLE) until the **condition** evaluates to true or signal is received. The **condition** is checked each time the waitqueue **wq_head** is woken up.

wake_up() has to be called after changing any variable that could change the result of the wait condition.

This is supposed to be called while holding the lock. The lock is dropped before going to sleep and is reacquired afterwards.

The macro will return -ERESTARTSYS if it was interrupted by a signal and 0 if **condition** evaluated to true.

wait_event_interruptible_lock_irq_timeout(wq_head, condition, lock, timeout)
sleep until a condition gets true or a timeout elapses. The condition is checked under the lock. This is expected to be called with the lock taken.

Parameters

wq_head the waitqueue to wait on

condition a C expression for the event to wait for

lock a locked spinlock_t, which will be released before schedule() and reacquired afterwards.

timeout timeout, in jiffies

Description

The process is put to sleep (TASK_INTERRUPTIBLE) until the **condition** evaluates to true or signal is received. The **condition** is checked each time the waitqueue **wq_head** is woken up.

wake_up() has to be called after changing any variable that could change the result of the wait condition.

This is supposed to be called while holding the lock. The lock is dropped before going to sleep and is reacquired afterwards.

The function returns 0 if the **timeout** elapsed, -ERESTARTSYS if it was interrupted by a signal, and the remaining jiffies otherwise if the condition evaluated to true before the timeout elapsed.

void **__wake_up**(struct wait_queue_head * wq_head, unsigned int mode, int nr_exclusive, void * key)
wake up threads blocked on a waitqueue.

Parameters

struct wait_queue_head * wq_head the waitqueue

unsigned int mode which threads

int nr_exclusive how many wake-one or wake-many threads to wake up

void * key is directly passed to the wakeup function

Description

If this function wakes up a task, it executes a full memory barrier before accessing the task state.

void **__wake_up_sync_key**(struct wait_queue_head * wq_head, unsigned int mode, void * key)
wake up threads blocked on a waitqueue.

Parameters

struct wait_queue_head * wq_head the waitqueue

unsigned int mode which threads

void * key opaque value to be passed to wakeup targets

Description

The sync wakeup differs that the waker knows that it will schedule away soon, so while the target thread will be woken up, it will not be migrated to another CPU - ie. the two threads are 'synchronized' with each other. This can prevent needless bouncing between CPUs.

On UP it can prevent extra preemption.

If this function wakes up a task, it executes a full memory barrier before accessing the task state.

void **__wake_up_locked_sync_key**(struct wait_queue_head * wq_head, unsigned int mode, void * key)
wake up a thread blocked on a locked waitqueue.

Parameters

struct wait_queue_head * wq_head the waitqueue

unsigned int mode which threads

void * key opaque value to be passed to wakeup targets

Description

The sync wakeup differs in that the waker knows that it will schedule away soon, so while the target thread will be woken up, it will not be migrated to another CPU - ie. the two threads are 'synchronized' with each other. This can prevent needless bouncing between CPUs.

On UP it can prevent extra preemption.

If this function wakes up a task, it executes a full memory barrier before accessing the task state.

void **finish_wait**(struct wait_queue_head * wq_head, struct wait_queue_entry * wq_entry)
clean up after waiting in a queue

Parameters

struct wait_queue_head * wq_head waitqueue waited on

struct wait_queue_entry * wq_entry wait descriptor

Description

Sets current thread back to running state and removes the wait descriptor from the given waitqueue if still queued.

2.5 High-resolution timers

ktime_t **ktime_set**(const s64 secs, const unsigned long nsecs)
Set a ktime_t variable from a seconds/nanoseconds value

Parameters

const s64 secs seconds to set

const unsigned long nsecs nanoseconds to set

Return

The ktime_t representation of the value.

int **ktime_compare**(const ktime_t cmp1, const ktime_t cmp2)
Compares two ktime_t variables for less, greater or equal

Parameters

const ktime_t cmp1 comparable1

const ktime_t cmp2 comparable2

Return

… cmp1 < cmp2: return <0 cmp1 == cmp2: return 0 cmp1 > cmp2: return >0

bool **ktime_after**(const ktime_t cmp1, const ktime_t cmp2)
Compare if a ktime_t value is bigger than another one.

Parameters

const ktime_t cmp1 comparable1

const ktime_t cmp2 comparable2

Return

true if cmp1 happened after cmp2.

bool **ktime_before**(const ktime_t cmp1, const ktime_t cmp2)
Compare if a ktime_t value is smaller than another one.

Parameters

const ktime_t cmp1 comparable1

const ktime_t cmp2 comparable2

Return

true if cmp1 happened before cmp2.

bool **ktime_to_timespec64_cond**(const ktime_t kt, struct timespec64 * ts)
convert a ktime_t variable to timespec64 format only if the variable contains data

Parameters

const ktime_t kt the ktime_t variable to convert

struct timespec64 * ts the timespec variable to store the result in

Return

`true` if there was a successful conversion, `false` if kt was 0.

struct **hrtimer**
the basic hrtimer structure

Definition

```
struct hrtimer {
  struct timerqueue_node          node;
  ktime_t _softexpires;
  enum hrtimer_restart            (*function)(struct hrtimer *);
  struct hrtimer_clock_base       *base;
  u8 state;
  u8 is_rel;
  u8 is_soft;
  u8 is_hard;
};
```

Members

node timerqueue node, which also manages node.expires, the absolute expiry time in the hrtimers internal representation. The time is related to the clock on which the timer is based. Is setup by adding slack to the _softexpires value. For non range timers identical to _softexpires.

_softexpires the absolute earliest expiry time of the hrtimer. The time which was given as expiry time when the timer was armed.

function timer expiry callback function

base pointer to the timer base (per cpu and per clock)

state state information (See bit values above)

is_rel Set if the timer was armed relative

is_soft Set if hrtimer will be expired in soft interrupt context.

is_hard Set if hrtimer will be expired in hard interrupt context even on RT.

Description

The hrtimer structure must be initialized by `hrtimer_init()`

struct **hrtimer_sleeper**
simple sleeper structure

Definition

```
struct hrtimer_sleeper {
  struct hrtimer timer;
  struct task_struct *task;
};
```

Members

timer embedded timer structure

task task to wake up

Description

task is set to NULL, when the timer expires.

struct **hrtimer_clock_base**
the timer base for a specific clock

Definition

```
struct hrtimer_clock_base {
  struct hrtimer_cpu_base *cpu_base;
  unsigned int            index;
  clockid_t clockid;
  seqcount_t seq;
  struct hrtimer          *running;
  struct timerqueue_head  active;
  ktime_t (*get_time)(void);
  ktime_t offset;
};
```

Members

cpu_base per cpu clock base

index clock type index for per_cpu support when moving a timer to a base on another cpu.

clockid clock id for per_cpu support

seq seqcount around __run_hrtimer

running pointer to the currently running hrtimer

active red black tree root node for the active timers

get_time function to retrieve the current time of the clock

offset offset of this clock to the monotonic base

struct **hrtimer_cpu_base**
the per cpu clock bases

Definition

```
struct hrtimer_cpu_base {
  raw_spinlock_t lock;
  unsigned int                    cpu;
  unsigned int                    active_bases;
  unsigned int                    clock_was_set_seq;
  unsigned int                    hres_active             : 1,in_hrtirq
↪           : 1,hang_detected          : 1, softirq_activated       : 1;
#ifdef CONFIG_HIGH_RES_TIMERS;
  unsigned int                    nr_events;
  unsigned short                  nr_retries;
  unsigned short                  nr_hangs;
  unsigned int                    max_hang_time;
#endif;
#ifdef CONFIG_PREEMPT_RT;
  spinlock_t softirq_expiry_lock;
  atomic_t timer_waiters;
#endif;
  ktime_t expires_next;
  struct hrtimer                  *next_timer;
  ktime_t softirq_expires_next;
  struct hrtimer                  *softirq_next_timer;
  struct hrtimer_clock_base       clock_base[HRTIMER_MAX_CLOCK_BASES];
};
```

Members

lock lock protecting the base and associated clock bases and timers

cpu cpu number

active_bases Bitfield to mark bases with active timers

clock_was_set_seq Sequence counter of clock was set events

hres_active State of high resolution mode

in_hrtirq hrtimer_interrupt() is currently executing

hang_detected The last hrtimer interrupt detected a hang

softirq_activated displays, if the softirq is raised - update of softirq related settings is not required then.

nr_events Total number of hrtimer interrupt events

nr_retries Total number of hrtimer interrupt retries

nr_hangs Total number of hrtimer interrupt hangs

max_hang_time Maximum time spent in hrtimer_interrupt

softirq_expiry_lock Lock which is taken while softirq based hrtimer are expired

timer_waiters A `hrtimer_cancel()` invocation waits for the timer callback to finish.

expires_next absolute time of the next event, is required for remote hrtimer enqueue; it is the total first expiry time (hard and soft hrtimer are taken into account)

next_timer Pointer to the first expiring timer

softirq_expires_next Time to check, if soft queues needs also to be expired

softirq_next_timer Pointer to the first expiring softirq based timer

clock_base array of clock bases for this cpu

Note

next_timer is just an optimization for __remove_hrtimer(). Do not dereference the pointer because it is not reliable on cross cpu removals.

void **hrtimer_start**(struct hrtimer * timer, ktime_t tim, const enum hrtimer_mode mode)
(re)start an hrtimer

Parameters

struct hrtimer * timer the timer to be added

ktime_t tim expiry time

const enum hrtimer_mode mode timer mode: absolute (HRTIMER_MODE_ABS) or relative (HRTIMER_MODE_REL), and pinned (HRTIMER_MODE_PINNED); softirq based mode is considered for debug purpose only!

bool **hrtimer_is_queued**(struct hrtimer * timer)

Parameters

struct hrtimer * timer Timer to check

Return

True if the timer is queued, false otherwise

Description

The function can be used lockless, but it gives only a current snapshot.

u64 **hrtimer_forward_now**(struct hrtimer * timer, ktime_t interval)
forward the timer expiry so it expires after now

Parameters

struct hrtimer * timer hrtimer to forward

ktime_t interval the interval to forward

Description

Forward the timer expiry so it will expire after the current time of the hrtimer clock base. Returns the number of overruns.

Can be safely called from the callback function of **timer**. If called from other contexts **timer** must neither be enqueued nor running the callback and the caller needs to take care of serialization.

Note

This only updates the timer expiry value and does not requeue the timer.

u64 **hrtimer_forward**(struct hrtimer * timer, ktime_t now, ktime_t interval)
forward the timer expiry

Parameters

struct hrtimer * timer hrtimer to forward

ktime_t now forward past this time

ktime_t interval the interval to forward

Description

Forward the timer expiry so it will expire in the future. Returns the number of overruns.

Can be safely called from the callback function of **timer**. If called from other contexts **timer** must neither be enqueued nor running the callback and the caller needs to take care of serialization.

Note

This only updates the timer expiry value and does not requeue the timer.

void **hrtimer_start_range_ns**(struct hrtimer * timer, ktime_t tim, u64 delta_ns, const enum hrtimer_mode mode)
(re)start an hrtimer

Parameters

struct hrtimer * timer the timer to be added

ktime_t tim expiry time

u64 delta_ns “slack” range for the timer

const enum hrtimer_mode mode timer mode: absolute (HRTIMER_MODE_ABS) or relative (HRTIMER_MODE_REL), and pinned (HRTIMER_MODE_PINNED); softirq based mode is considered for debug purpose only!

int **hrtimer_try_to_cancel**(struct hrtimer * timer)
try to deactivate a timer

Parameters

struct hrtimer * timer hrtimer to stop

Return

- 0 when the timer was not active
- 1 when the timer was active
- -1 when the timer is currently executing the callback function and cannot be stopped

int **hrtimer_cancel**(struct hrtimer * timer)
cancel a timer and wait for the handler to finish.

Parameters

struct hrtimer * timer the timer to be cancelled

Return

0 when the timer was not active 1 when the timer was active

ktime_t **__hrtimer_get_remaining**(const struct hrtimer * timer, bool adjust)
get remaining time for the timer

Parameters

const struct hrtimer * timer the timer to read

bool adjust adjust relative timers when CONFIG_TIME_LOW_RES=y

void **hrtimer_init**(struct hrtimer * timer, clockid_t clock_id, enum hrtimer_mode mode)
initialize a timer to the given clock

Parameters

struct hrtimer * timer the timer to be initialized

clockid_t clock_id the clock to be used

enum hrtimer_mode mode The modes which are relevant for initialization: HRTIMER_MODE_ABS, HRTIMER_MODE_REL, HRTIMER_MODE_ABS_SOFT, HRTIMER_MODE_REL_SOFT

The PINNED variants of the above can be handed in, but the PINNED bit is ignored as pinning happens when the hrtimer is started

void **hrtimer_sleeper_start_expires**(struct hrtimer_sleeper * sl, enum hrtimer_mode mode)
Start a hrtimer sleeper timer

Parameters

struct hrtimer_sleeper * sl sleeper to be started

enum hrtimer_mode mode timer mode abs/rel

Description

Wrapper around hrtimer_start_expires() for hrtimer_sleeper based timers to allow PREEMPT_RT to tweak the delivery mode (soft/hardirq context)

void **hrtimer_init_sleeper**(struct hrtimer_sleeper * sl, clockid_t clock_id, enum hrtimer_mode mode)
initialize sleeper to the given clock

Parameters

struct hrtimer_sleeper * sl sleeper to be initialized

clockid_t clock_id the clock to be used

enum hrtimer_mode mode timer mode abs/rel

int **schedule_hrtimeout_range**(ktime_t * expires, u64 delta, const enum hrtimer_mode mode)
sleep until timeout

Parameters

ktime_t * expires timeout value (ktime_t)

u64 delta slack in expires timeout (ktime_t)

const enum hrtimer_mode mode timer mode

Description

Make the current task sleep until the given expiry time has elapsed. The routine will return immediately unless the current task state has been set (see set_current_state()).

The **delta** argument gives the kernel the freedom to schedule the actual wakeup to a time that is both power and performance friendly. The kernel give the normal best effort behavior for "**expires**+**delta**", but may decide to fire the timer earlier, but no earlier than **expires**.

You can set the task state as follows -

TASK_UNINTERRUPTIBLE - at least **timeout** time is guaranteed to pass before the routine returns unless the current task is explicitly woken up, (e.g. by wake_up_process()).

TASK_INTERRUPTIBLE - the routine may return early if a signal is delivered to the current task or the current task is explicitly woken up.

The current task state is guaranteed to be TASK_RUNNING when this routine returns.

Returns 0 when the timer has expired. If the task was woken before the timer expired by a signal (only possible in state TASK_INTERRUPTIBLE) or by an explicit wakeup, it returns -EINTR.

int **schedule_hrtimeout**(ktime_t * expires, const enum hrtimer_mode mode)

sleep until timeout

Parameters

ktime_t * expires timeout value (ktime_t)

const enum hrtimer_mode mode timer mode

Description

Make the current task sleep until the given expiry time has elapsed. The routine will return immediately unless the current task state has been set (see set_current_state()).

You can set the task state as follows -

TASK_UNINTERRUPTIBLE - at least **timeout** time is guaranteed to pass before the routine returns unless the current task is explicitly woken up, (e.g. by wake_up_process()).

TASK_INTERRUPTIBLE - the routine may return early if a signal is delivered to the current task or the current task is explicitly woken up.

The current task state is guaranteed to be TASK_RUNNING when this routine returns.

Returns 0 when the timer has expired. If the task was woken before the timer expired by a signal (only possible in state TASK_INTERRUPTIBLE) or by an explicit

wakeup, it returns -EINTR.

2.6 Workqueues and Kevents

struct **workqueue_attrs**
A struct for workqueue attributes.

Definition

```
struct workqueue_attrs {
  int nice;
  cpumask_var_t cpumask;
  bool no_numa;
};
```

Members

nice nice level

cpumask allowed CPUs

no_numa disable NUMA affinity

Unlike other fields, `no_numa` isn't a property of a worker_pool. It only modifies how `apply_workqueue_attrs()` select pools and thus doesn't participate in pool hash calculations or equality comparisons.

Description

This can be used to change attributes of an unbound workqueue.

work_pending(work)
Find out whether a work item is currently pending

Parameters

work The work item in question

delayed_work_pending(w)
Find out whether a delayable work item is currently pending

Parameters

w The work item in question

struct workqueue_struct * **alloc_workqueue**(const char * fmt, unsigned int flags, int max_active, ...)
allocate a workqueue

Parameters

const char * fmt printf format for the name of the workqueue

unsigned int flags WQ_* flags

int max_active max in-flight work items, 0 for default remaining args: args for **fmt**

... variable arguments

Description

Allocate a workqueue with the specified parameters. For detailed information on WQ_* flags, please refer to Documentation/core-api/workqueue.rst.

Return

Pointer to the allocated workqueue on success, `NULL` on failure.

alloc_ordered_workqueue(fmt, flags, args)
allocate an ordered workqueue

Parameters

fmt printf format for the name of the workqueue

flags WQ_* flags (only WQ_FREEZABLE and WQ_MEM_RECLAIM are meaningful)

args args for **fmt**

Description

Allocate an ordered workqueue. An ordered workqueue executes at most one work item at any given time in the queued order. They are implemented as unbound workqueues with **max_active** of one.

Return

Pointer to the allocated workqueue on success, `NULL` on failure.

bool **queue_work**(struct workqueue_struct * wq, struct work_struct * work)
queue work on a workqueue

Parameters

struct workqueue_struct * wq workqueue to use

struct work_struct * work work to queue

Description

Returns `false` if **work** was already on a queue, `true` otherwise.

We queue the work to the CPU on which it was submitted, but if the CPU dies it can be processed by another CPU.

Memory-ordering properties: If it returns `true`, guarantees that all stores preceding the call to queue_work() in the program order will be visible from the CPU which will execute **work** by the time such work executes, e.g.,

{ x is initially 0 }

CPU0 CPU1

WRITE_ONCE(x, 1); [**work** is being executed] r0 = queue_work(wq, work); r1 = READ_ONCE(x);

Forbids: r0 == true && r1 == 0

bool **queue_delayed_work**(struct workqueue_struct * wq, struct delayed_work * dwork, unsigned long delay)
queue work on a workqueue after delay

Parameters

struct workqueue_struct * wq workqueue to use

struct delayed_work * dwork delayable work to queue

unsigned long delay number of jiffies to wait before queueing

Description

Equivalent to `queue_delayed_work_on()` but tries to use the local CPU.

bool **mod_delayed_work**(struct workqueue_struct * wq, struct delayed_work * dwork, unsigned long delay)
modify delay of or queue a delayed work

Parameters

struct workqueue_struct * wq workqueue to use

struct delayed_work * dwork work to queue

unsigned long delay number of jiffies to wait before queueing

Description

`mod_delayed_work_on()` on local CPU.

bool **schedule_work_on**(int cpu, struct work_struct * work)
put work task on a specific cpu

Parameters

int cpu cpu to put the work task on

struct work_struct * work job to be done

Description

This puts a job on a specific cpu

bool **schedule_work**(struct work_struct * work)
put work task in global workqueue

Parameters

struct work_struct * work job to be done

Description

Returns `false` if **work** was already on the kernel-global workqueue and `true` otherwise.

This puts a job in the kernel-global workqueue if it was not already queued and leaves it in the same position on the kernel-global workqueue otherwise.

Shares the same memory-ordering properties of queue_work(), cf. the DocBook header of queue_work().

void **flush_scheduled_work**(void)
ensure that any scheduled work has run to completion.

Parameters

void no arguments

Description

Forces execution of the kernel-global workqueue and blocks until its completion.

Think twice before calling this function! It's very easy to get into trouble if you don't take great care. Either of the following situations will lead to deadlock:

> One of the work items currently on the workqueue needs to acquire a lock held by your code or its caller.
>
> Your code is running in the context of a work routine.

They will be detected by lockdep when they occur, but the first might not occur very often. It depends on what work items are on the workqueue and what locks they need, which you have no control over.

In most situations flushing the entire workqueue is overkill; you merely need to know that a particular work item isn't queued and isn't running. In such cases you should use `cancel_delayed_work_sync()` or `cancel_work_sync()` instead.

bool **schedule_delayed_work_on**(int cpu, struct delayed_work * dwork, unsigned long delay)
queue work in global workqueue on CPU after delay

Parameters

int cpu cpu to use

struct delayed_work * dwork job to be done

unsigned long delay number of jiffies to wait

Description

After waiting for a given time this puts a job in the kernel-global workqueue on the specified CPU.

bool **schedule_delayed_work**(struct delayed_work * dwork, unsigned long delay)
put work task in global workqueue after delay

Parameters

struct delayed_work * dwork job to be done

unsigned long delay number of jiffies to wait or 0 for immediate execution

Description

After waiting for a given time this puts a job in the kernel-global workqueue.

bool **queue_work_on**(int cpu, struct workqueue_struct * wq, struct work_struct * work)
queue work on specific cpu

Parameters

int cpu CPU number to execute work on

struct workqueue_struct * wq workqueue to use

struct work_struct * work work to queue

Description

We queue the work to a specific CPU, the caller must ensure it can't go away.

Return

`false` if **work** was already on a queue, `true` otherwise.

bool **queue_work_node**(int node, struct workqueue_struct * wq, struct work_struct * work)
queue work on a "random" cpu for a given NUMA node

Parameters

int node NUMA node that we are targeting the work for

struct workqueue_struct * wq workqueue to use

struct work_struct * work work to queue

Description

We queue the work to a "random" CPU within a given NUMA node. The basic idea here is to provide a way to somehow associate work with a given NUMA node.

This function will only make a best effort attempt at getting this onto the right NUMA node. If no node is requested or the requested node is offline then we just fall back to standard queue_work behavior.

Currently the "random" CPU ends up being the first available CPU in the intersection of cpu_online_mask and the cpumask of the node, unless we are running on the node. In that case we just use the current CPU.

Return

`false` if **work** was already on a queue, `true` otherwise.

bool **queue_delayed_work_on**(int cpu, struct workqueue_struct * wq, struct delayed_work * dwork, unsigned long delay)
queue work on specific CPU after delay

Parameters

int cpu CPU number to execute work on

struct workqueue_struct * wq workqueue to use

struct delayed_work * dwork work to queue

unsigned long delay number of jiffies to wait before queueing

Return

`false` if **work** was already on a queue, `true` otherwise. If **delay** is zero and **dwork** is idle, it will be scheduled for immediate execution.

bool **mod_delayed_work_on**(int cpu, struct workqueue_struct * wq, struct delayed_work * dwork, unsigned long delay)
modify delay of or queue a delayed work on specific CPU

Parameters

int cpu CPU number to execute work on

struct workqueue_struct * wq workqueue to use

struct delayed_work * dwork work to queue

unsigned long delay number of jiffies to wait before queueing

Description

If **dwork** is idle, equivalent to `queue_delayed_work_on();` otherwise, modify **dwork**' s timer so that it expires after **delay**. If **delay** is zero, **work** is guaranteed to be scheduled immediately regardless of its current state.

This function is safe to call from any context including IRQ handler. See try_to_grab_pending() for details.

Return

`false` if **dwork** was idle and queued, `true` if **dwork** was pending and its timer was modified.

bool **queue_rcu_work**(struct workqueue_struct * wq, struct rcu_work * rwork)
queue work after a RCU grace period

Parameters

struct workqueue_struct * wq workqueue to use

struct rcu_work * rwork work to queue

Return

`false` if **rwork** was already pending, `true` otherwise. Note that a full RCU grace period is guaranteed only after a `true` return. While **rwork** is guaranteed to be executed after a `false` return, the execution may happen before a full RCU grace period has passed.

void **flush_workqueue**(struct workqueue_struct * wq)
ensure that any scheduled work has run to completion.

Parameters

struct workqueue_struct * wq workqueue to flush

Description

This function sleeps until all work items which were queued on entry have finished execution, but it is not livelocked by new incoming ones.

void **drain_workqueue**(struct workqueue_struct * wq)
drain a workqueue

Parameters

struct workqueue_struct * wq workqueue to drain

Description

Wait until the workqueue becomes empty. While draining is in progress, only chain queueing is allowed. IOW, only currently pending or running work items on **wq** can queue further work items on it. **wq** is flushed repeatedly until it becomes empty. The number of flushing is determined by the depth of chaining and should be relatively short. Whine if it takes too long.

bool **flush_work**(struct work_struct * work)
wait for a work to finish executing the last queueing instance

Parameters

struct work_struct * work the work to flush

Description

Wait until **work** has finished execution. **work** is guaranteed to be idle on return if it hasn't been requeued since flush started.

Return

`true` if `flush_work()` waited for the work to finish execution, `false` if it was already idle.

bool **cancel_work_sync**(struct work_struct * work)
cancel a work and wait for it to finish

Parameters

struct work_struct * work the work to cancel

Description

Cancel **work** and wait for its execution to finish. This function can be used even if the work re-queues itself or migrates to another workqueue. On return from this function, **work** is guaranteed to be not pending or executing on any CPU.

cancel_work_sync(`delayed_work->work`) must not be used for delayed_work's. Use `cancel_delayed_work_sync()` instead.

The caller must ensure that the workqueue on which **work** was last queued can't be destroyed before this function returns.

Return

`true` if **work** was pending, `false` otherwise.

bool **flush_delayed_work**(struct delayed_work * dwork)
wait for a dwork to finish executing the last queueing

Parameters

struct delayed_work * dwork the delayed work to flush

Description

Delayed timer is cancelled and the pending work is queued for immediate execution. Like `flush_work()`, this function only considers the last queueing instance of **dwork**.

Return

`true` if `flush_work()` waited for the work to finish execution, `false` if it was already idle.

bool **flush_rcu_work**(struct rcu_work * rwork)
wait for a rwork to finish executing the last queueing

Parameters

struct rcu_work * rwork the rcu work to flush

Return

`true` if `flush_rcu_work()` waited for the work to finish execution, `false` if it was already idle.

bool **cancel_delayed_work**(struct delayed_work * dwork)
cancel a delayed work

Parameters

struct delayed_work * dwork delayed_work to cancel

Description

Kill off a pending delayed_work.

This function is safe to call from any context including IRQ handler.

Return

`true` if **dwork** was pending and canceled; `false` if it wasn't pending.

Note

The work callback function may still be running on return, unless it returns `true` and the work doesn't re-arm itself. Explicitly flush or use `cancel_delayed_work_sync()` to wait on it.

bool **cancel_delayed_work_sync**(struct delayed_work * dwork)
cancel a delayed work and wait for it to finish

Parameters

struct delayed_work * dwork the delayed work cancel

Description

This is `cancel_work_sync()` for delayed works.

Return

`true` if **dwork** was pending, `false` otherwise.

int **execute_in_process_context**(work_func_t fn, struct execute_work * ew)
reliably execute the routine with user context

Parameters

work_func_t fn the function to execute

struct execute_work * ew guaranteed storage for the execute work structure (must be available when the work executes)

Description

Executes the function immediately if process context is available, otherwise schedules the function for delayed execution.

Return

0 - function was executed 1 - function was scheduled for execution

void **destroy_workqueue**(struct workqueue_struct * wq)
safely terminate a workqueue

Parameters

struct workqueue_struct * wq target workqueue

Description

Safely destroy a workqueue. All work currently pending will be done first.

void **workqueue_set_max_active**(struct workqueue_struct * wq, int max_active)
adjust max_active of a workqueue

Parameters

struct workqueue_struct * wq target workqueue

int max_active new max_active value.

Description

Set max_active of **wq** to **max_active**.

Context

Don't call from IRQ context.

struct work_struct * **current_work**(void)
retrieve `current` task's work struct

Parameters

void no arguments

Description

Determine if `current` task is a workqueue worker and what it's working on. Useful to find out the context that the `current` task is running in.

Return

work struct if `current` task is a workqueue worker, `NULL` otherwise.

bool **workqueue_congested**(int cpu, struct workqueue_struct * wq)
test whether a workqueue is congested

Parameters

int cpu CPU in question

struct workqueue_struct * wq target workqueue

Description

Test whether **wq**'s cpu workqueue for **cpu** is congested. There is no synchronization around this function and the test result is unreliable and only useful as advisory hints or for debugging.

If **cpu** is WORK_CPU_UNBOUND, the test is performed on the local CPU. Note that both per-cpu and unbound workqueues may be associated with multiple pool_workqueues which have separate congested states. A workqueue being congested on one CPU doesn't mean the workqueue is also contested on other CPUs / NUMA nodes.

Return

`true` if congested, `false` otherwise.

unsigned int **work_busy**(struct work_struct * work)
test whether a work is currently pending or running

Parameters

struct work_struct * work the work to be tested

Description

Test whether **work** is currently pending or running. There is no synchronization around this function and the test result is unreliable and only useful as advisory hints or for debugging.

Return

OR'd bitmask of WORK_BUSY_* bits.

void **set_worker_desc**(const char * fmt, ...)
set description for the current work item

Parameters

const char * fmt printf-style format string

... arguments for the format string

Description

This function can be called by a running work function to describe what the work item is about. If the worker task gets dumped, this information will be printed out together to help debugging. The description can be at most WORKER_DESC_LEN including the trailing '0'.

long **work_on_cpu**(int cpu, long (*fn)(void *), void * arg)
run a function in thread context on a particular cpu

Parameters

int cpu the cpu to run on

long (*)(void *) fn the function to run

void * arg the function arg

Description

It is up to the caller to ensure that the cpu doesn't go offline. The caller must not hold any locks which would prevent **fn** from completing.

Return

The value **fn** returns.

long **work_on_cpu_safe**(int cpu, long (*fn)(void *), void * arg)
run a function in thread context on a particular cpu

Parameters

int cpu the cpu to run on

long (*)(void *) fn the function to run

void * arg the function argument

Description

Disables CPU hotplug and calls `work_on_cpu()`. The caller must not hold any locks which would prevent **fn** from completing.

Return

The value **fn** returns.

2.7 Internal Functions

int **wait_task_stopped**(struct wait_opts * wo, int ptrace, struct task_struct * p)
Wait for `TASK_STOPPED` or `TASK_TRACED`

Parameters

struct wait_opts * wo wait options

int ptrace is the wait for ptrace

struct task_struct * p task to wait for

Description

Handle sys_wait4() work for `p` in state `TASK_STOPPED` or `TASK_TRACED`.

Context

read_lock(`tasklist_lock`), which is released if return value is non-zero. Also, grabs and releases **p->sighand->siglock**.

Return

0 if wait condition didn't exist and search for other wait conditions should continue. Non-zero return, -errno on failure and **p**'s pid on success, implies that tasklist_lock is released and wait condition search should terminate.

bool **task_set_jobctl_pending**(struct task_struct * task, unsigned long mask)
set jobctl pending bits

Parameters

struct task_struct * task target task

unsigned long mask pending bits to set

Description

Clear **mask** from **task->jobctl**. **mask** must be subset of `JOBCTL_PENDING_MASK` | `JOBCTL_STOP_CONSUME` | `JOBCTL_STOP_SIGMASK` | `JOBCTL_TRAPPING`. If stop signo is being set, the existing signo is cleared. If **task** is already being killed or exiting, this function becomes noop.

Context

Must be called with **task->sighand->siglock** held.

Return

`true` if **mask** is set, `false` if made noop because **task** was dying.

void **task_clear_jobctl_trapping**(struct task_struct * task)
clear jobctl trapping bit

Parameters

struct task_struct * task target task

Description

If JOBCTL_TRAPPING is set, a ptracer is waiting for us to enter TRACED. Clear it and wake up the ptracer. Note that we don't need any further locking. **task->siglock** guarantees that **task->parent** points to the ptracer.

Context

Must be called with **task->sighand->siglock** held.

void **task_clear_jobctl_pending**(struct task_struct * task, unsigned long mask)
clear jobctl pending bits

Parameters

struct task_struct * task target task

unsigned long mask pending bits to clear

Description

Clear **mask** from **task->jobctl**. **mask** must be subset of `JOBCTL_PENDING_MASK`. If `JOBCTL_STOP_PENDING` is being cleared, other STOP bits are cleared together.

If clearing of **mask** leaves no stop or trap pending, this function calls `task_clear_jobctl_trapping()`.

Context

Must be called with **task->sighand->siglock** held.

bool **task_participate_group_stop**(struct task_struct * task)
participate in a group stop

Parameters

struct task_struct * task task participating in a group stop

Description

task has `JOBCTL_STOP_PENDING` set and is participating in a group stop. Group stop states are cleared and the group stop count is consumed if `JOBCTL_STOP_CONSUME` was set. If the consumption completes the group stop, the appropriate SIGNAL_* flags are set.

Context

Must be called with **task->sighand->siglock** held.

Return

`true` if group stop completion should be notified to the parent, `false` otherwise.

void **ptrace_trap_notify**(struct task_struct * t)
schedule trap to notify ptracer

Parameters

struct task_struct * t tracee wanting to notify tracer

Description

This function schedules sticky ptrace trap which is cleared on the next TRAP_STOP to notify ptracer of an event. **t** must have been seized by ptracer.

If **t** is running, STOP trap will be taken. If trapped for STOP and ptracer is listening for events, tracee is woken up so that it can re-trap for the new event. If trapped otherwise, STOP trap will be eventually taken without returning to userland after the existing traps are finished by PTRACE_CONT.

Context

Must be called with **task->sighand->siglock** held.

void **do_notify_parent_cldstop**(struct task_struct * tsk, bool for_ptracer, int why)
notify parent of stopped/continued state change

Parameters

struct task_struct * tsk task reporting the state change

bool for_ptracer the notification is for ptracer

int why CLD_{CONTINUED|STOPPED|TRAPPED} to report

Description

Notify **tsk**'s parent that the stopped/continued state has changed. If **for_ptracer** is `false`, **tsk**'s group leader notifies to its real parent. If `true`, **tsk** reports to **tsk->parent** which should be the ptracer.

Context

Must be called with tasklist_lock at least read locked.

bool **do_signal_stop**(int signr)
handle group stop for SIGSTOP and other stop signals

Parameters

int signr signr causing group stop if initiating

Description

If `JOBCTL_STOP_PENDING` is not set yet, initiate group stop with **signr** and participate in it. If already set, participate in the existing group stop. If participated in a group stop (and thus slept), `true` is returned with siglock released.

If ptraced, this function doesn't handle stop itself. Instead, `JOBCTL_TRAP_STOP` is scheduled and `false` is returned with siglock untouched. The caller must ensure that INTERRUPT trap handling takes places afterwards.

Context

Must be called with **current->sighand->siglock** held, which is released on `true` return.

Return

`false` if group stop is already cancelled or ptrace trap is scheduled. `true` if participated in group stop.

void **do_jobctl_trap**(void)
take care of ptrace jobctl traps

Parameters

void no arguments

Description

When PT_SEIZED, it's used for both group stop and explicit SEIZE/INTERRUPT traps. Both generate PTRACE_EVENT_STOP trap with accompanying siginfo. If stopped, lower eight bits of exit_code contain the stop signal; otherwise, `SIGTRAP`.

When !PT_SEIZED, it's used only for group stop trap with stop signal number as exit_code and no siginfo.

Context

Must be called with **current->sighand->siglock** held, which may be released and re-acquired before returning with intervening sleep.

void **do_freezer_trap**(void)
handle the freezer jobctl trap

Parameters

void no arguments

Description

Puts the task into frozen state, if only the task is not about to quit. In this case it drops JOBCTL_TRAP_FREEZE.

Context

Must be called with **current->sighand->siglock** held, which is always released before returning.

void **signal_delivered**(struct ksignal * ksig, int stepping)

Parameters

struct ksignal * ksig kernel signal struct

int stepping nonzero if debugger single-step or block-step in use

Description

This function should be called when a signal has successfully been delivered. It updates the blocked signals accordingly (**ksig->ka.sa.sa_mask** is always blocked, and the signal itself is blocked unless `SA_NODEFER` is set in **ksig->ka.sa.sa_flags**. Tracing is notified.

long **sys_restart_syscall**(void)
restart a system call

Parameters

void no arguments

void **set_current_blocked**(sigset_t * newset)
change current->blocked mask

Parameters

sigset_t * newset new mask

Description

It is wrong to change ->blocked directly, this helper should be used to ensure the process can't miss a shared signal we are going to block.

long **sys_rt_sigprocmask**(int how, sigset_t __user * nset, sigset_t __user * oset, size_t sigsetsize)
change the list of currently blocked signals

Parameters

int how whether to add, remove, or set signals

sigset_t __user * nset stores pending signals

sigset_t __user * oset previous value of signal mask if non-null

size_t sigsetsize size of sigset_t type

long **sys_rt_sigpending**(sigset_t __user * uset, size_t sigsetsize)
examine a pending signal that has been raised while blocked

Parameters

sigset_t __user * uset stores pending signals

size_t sigsetsize size of sigset_t type or larger

void **copy_siginfo_to_external32**(struct compat_siginfo * to, const struct kernel_siginfo * from)
copy a kernel siginfo into a compat user siginfo

Parameters

struct compat_siginfo * to compat siginfo destination

const struct kernel_siginfo * from kernel siginfo source

Note

This function does not work properly for the SIGCHLD on x32, but fortunately it doesn't have to. The only valid callers for this function are copy_siginfo_to_user32, which is overriden for x32 and the coredump code. The latter does not care because SIGCHLD will never cause a coredump.

int **do_sigtimedwait**(const sigset_t * which, kernel_siginfo_t * info, const struct timespec64 * ts)
wait for queued signals specified in **which**

Parameters

const sigset_t * which queued signals to wait for

kernel_siginfo_t * info if non-null, the signal's siginfo is returned here

const struct timespec64 * ts upper bound on process time suspension

long **sys_rt_sigtimedwait**(const sigset_t __user * uthese, siginfo_t __user * uinfo, const struct __kernel_timespec __user * uts, size_t sigsetsize)
synchronously wait for queued signals specified in **uthese**

Parameters

const sigset_t __user * uthese queued signals to wait for

siginfo_t __user * uinfo if non-null, the signal's siginfo is returned here

const struct __kernel_timespec __user * uts upper bound on process time suspension

size_t sigsetsize size of sigset_t type

long **sys_kill**(pid_t pid, int sig)
send a signal to a process

Parameters

pid_t pid the PID of the process

int sig signal to be sent

long **sys_pidfd_send_signal**(int pidfd, int sig, siginfo_t __user * info, unsigned int flags)
Signal a process through a pidfd

Parameters

int pidfd file descriptor of the process

int sig signal to send

siginfo_t __user * info signal info

unsigned int flags future flags

Description

The syscall currently only signals via PIDTYPE_PID which covers kill(<positive-pid>, <signal>. It does not signal threads or process groups. In order to extend the syscall to threads and process groups the **flags** argument should be used. In essence, the **flags** argument will determine what is signaled and not the file descriptor itself. Put in other words, grouping is a property of the flags argument not a property of the file descriptor.

Return

0 on success, negative errno on failure

long **sys_tgkill**(pid_t tgid, pid_t pid, int sig)
send signal to one specific thread

Parameters

pid_t tgid the thread group ID of the thread

pid_t pid the PID of the thread

int sig signal to be sent

This syscall also checks the **tgid** and returns -ESRCH even if the PID exists but it's not belonging to the target process anymore. This method solves the problem of threads exiting and PIDs getting reused.

long **sys_tkill**(pid_t pid, int sig)
send signal to one specific task

Parameters

pid_t pid the PID of the task

int sig signal to be sent

Send a signal to only one task, even if it's a CLONE_THREAD task.

long **sys_rt_sigqueueinfo**(pid_t pid, int sig, siginfo_t __user * uinfo)
send signal information to a signal

Parameters

pid_t pid the PID of the thread

int sig signal to be sent

siginfo_t __user * uinfo signal info to be sent

long **sys_sigpending**(old_sigset_t __user * uset)
examine pending signals

Parameters

old_sigset_t __user * uset where mask of pending signal is returned

long **sys_sigprocmask**(int how, old_sigset_t __user * nset, old_sigset_t __user * oset)
examine and change blocked signals

Parameters

int how whether to add, remove, or set signals

old_sigset_t __user * nset signals to add or remove (if non-null)

old_sigset_t __user * oset previous value of signal mask if non-null

Description

Some platforms have their own version with special arguments; others support only sys_rt_sigprocmask.

long **sys_rt_sigaction**(int sig, const struct sigaction __user * act, struct sigaction __user * oact, size_t sigsetsize)
alter an action taken by a process

Parameters

int sig signal to be sent

const struct sigaction __user * act new sigaction

struct sigaction __user * oact used to save the previous sigaction

size_t sigsetsize size of sigset_t type

long **sys_rt_sigsuspend**(sigset_t __user * unewset, size_t sigsetsize)
replace the signal mask for a value with the **unewset** value until a signal is received

Parameters

sigset_t __user * unewset new signal mask value

size_t sigsetsize size of sigset_t type

kthread_create(threadfn, data, namefmt, arg)
create a kthread on the current node

Parameters

threadfn the function to run in the thread

data data pointer for **threadfn()**

namefmt printf-style format string for the thread name

arg arguments for **namefmt**.

Description

This macro will create a kthread on the current node, leaving it in the stopped state. This is just a helper for `kthread_create_on_node()`; see the documentation there for more details.

kthread_run(threadfn, data, namefmt, ⋯)
create and wake a thread.

Parameters

threadfn the function to run until signal_pending(current).

data data ptr for **threadfn**.

namefmt printf-style name for the thread.

... variable arguments

Description

Convenient wrapper for `kthread_create()` followed by `wake_up_process()`. Returns the kthread or ERR_PTR(-ENOMEM).

bool **kthread_should_stop**(void)
should this kthread return now?

Parameters

void no arguments

Description

When someone calls `kthread_stop()` on your kthread, it will be woken and this will return true. You should then return, and your return value will be passed through to `kthread_stop()`.

bool **kthread_should_park**(void)
should this kthread park now?

Parameters

void no arguments

Description

When someone calls `kthread_park()` on your kthread, it will be woken and this will return true. You should then do the necessary cleanup and call kthread_parkme()

Similar to `kthread_should_stop()`, but this keeps the thread alive and in a park position. `kthread_unpark()` "restarts" the thread and calls the thread function again.

bool **kthread_freezable_should_stop**(bool * was_frozen)
should this freezable kthread return now?

Parameters

bool * was_frozen optional out parameter, indicates whether `current` was frozen

Description

`kthread_should_stop()` for freezable kthreads, which will enter refrigerator if necessary. This function is safe from `kthread_stop()` / freezer deadlock and freezable kthreads should use this function instead of calling try_to_freeze() directly.

void * **kthread_func**(struct task_struct * task)
return the function specified on kthread creation

Parameters

struct task_struct * task kthread task in question

Description

Returns NULL if the task is not a kthread.

void * **kthread_data**(struct task_struct * task)
return data value specified on kthread creation

Parameters

struct task_struct * task kthread task in question

Description

Return the data value specified when kthread **task** was created. The caller is responsible for ensuring the validity of **task** when calling this function.

struct task_struct * **kthread_create_on_node**(int (*threadfn)(void *data), void * data, int node, const char namefmt, ...)
create a kthread.

Parameters

int (*)(void *data) threadfn the function to run until signal_pending(current).

void * data data ptr for **threadfn**.

int node task and thread structures for the thread are allocated on this node

const char namefmt printf-style name for the thread.

... variable arguments

Description

This helper function creates and names a kernel thread. The thread will be stopped: use wake_up_process() to start it. See also kthread_run(). The new thread has SCHED_NORMAL policy and is affine to all CPUs.

If thread is going to be bound on a particular cpu, give its node in **node**, to get NUMA affinity for kthread stack, or else give NUMA_NO_NODE. When woken, the thread will run **threadfn()** with **data** as its argument. **threadfn()** can either call do_exit() directly if it is a standalone thread for which no one will call kthread_stop(), or return when 'kthread_should_stop()' is true (which means kthread_stop() has been called). The return value should be zero or a negative error number; it will be passed to kthread_stop().

Returns a task_struct or ERR_PTR(-ENOMEM) or ERR_PTR(-EINTR).

void **kthread_bind**(struct task_struct * p, unsigned int cpu)
bind a just-created kthread to a cpu.

Parameters

struct task_struct * p thread created by kthread_create().

unsigned int cpu cpu (might not be online, must be possible) for **k** to run on.

Description

This function is equivalent to set_cpus_allowed(), except that **cpu** doesn't need to be online, and the thread must be stopped (i.e., just returned from kthread_create()).

void **kthread_unpark**(struct task_struct * k)
unpark a thread created by kthread_create().

Parameters

struct task_struct * k thread created by kthread_create().

Description

Sets kthread_should_park() for **k** to return false, wakes it, and waits for it to return. If the thread is marked percpu then its bound to the cpu again.

int **kthread_park**(struct task_struct * k)
park a thread created by kthread_create().

Parameters

struct task_struct * k thread created by kthread_create().

Description

Sets kthread_should_park() for **k** to return true, wakes it, and waits for it to return. This can also be called after kthread_create() instead of calling wake_up_process(): the thread will park without calling threadfn().

Returns 0 if the thread is parked, -ENOSYS if the thread exited. If called by the kthread itself just the park bit is set.

int **kthread_stop**(struct task_struct * k)
stop a thread created by `kthread_create()`.

Parameters

struct task_struct * k thread created by `kthread_create()`.

Description

Sets `kthread_should_stop()` for **k** to return true, wakes it, and waits for it to exit. This can also be called after `kthread_create()` instead of calling `wake_up_process()`: the thread will exit without calling threadfn().

If threadfn() may call do_exit() itself, the caller must ensure task_struct can't go away.

Returns the result of threadfn(), or `-EINTR` if `wake_up_process()` was never called.

int **kthread_worker_fn**(void * worker_ptr)
kthread function to process kthread_worker

Parameters

void * worker_ptr pointer to initialized kthread_worker

Description

This function implements the main cycle of kthread worker. It processes work_list until it is stopped with `kthread_stop()`. It sleeps when the queue is empty.

The works are not allowed to keep any locks, disable preemption or interrupts when they finish. There is defined a safe point for freezing when one work finishes and before a new one is started.

Also the works must not be handled by more than one worker at the same time, see also `kthread_queue_work()`.

struct kthread_worker * **kthread_create_worker**(unsigned int flags, const char namefmt, ...)
create a kthread worker

Parameters

unsigned int flags flags modifying the default behavior of the worker

const char namefmt printf-style name for the kthread worker (task).

... variable arguments

Description

Returns a pointer to the allocated worker on success, ERR_PTR(-ENOMEM) when the needed structures could not get allocated, and ERR_PTR(-EINTR) when the worker was SIGKILLed.

struct kthread_worker * **kthread_create_worker_on_cpu**(int cpu, unsigned int flags, const char namefmt, ...)
create a kthread worker and bind it it to a given CPU and the associated NUMA node.

Parameters

int cpu CPU number

unsigned int flags flags modifying the default behavior of the worker

const char namefmt printf-style name for the kthread worker (task).

... variable arguments

Description

Use a valid CPU number if you want to bind the kthread worker to the given CPU and the associated NUMA node.

A good practice is to add the cpu number also into the worker name. For example, use kthread_create_worker_on_cpu(cpu, "helper/d", cpu).

Returns a pointer to the allocated worker on success, ERR_PTR(-ENOMEM) when the needed structures could not get allocated, and ERR_PTR(-EINTR) when the worker was SIGKILLed.

bool **kthread_queue_work**(struct kthread_worker * worker, struct kthread_work * work)
queue a kthread_work

Parameters

struct kthread_worker * worker target kthread_worker

struct kthread_work * work kthread_work to queue

Description

Queue **work** to work processor **task** for async execution. **task** must have been created with kthread_worker_create(). Returns `true` if **work** was successfully queued, `false` if it was already pending.

Reinitialize the work if it needs to be used by another worker. For example, when the worker was stopped and started again.

void **kthread_delayed_work_timer_fn**(struct timer_list * t)
callback that queues the associated kthread delayed work when the timer expires.

Parameters

struct timer_list * t pointer to the expired timer

Description

The format of the function is defined by struct timer_list. It should have been called from irqsafe timer with irq already off.

bool **kthread_queue_delayed_work**(struct kthread_worker * worker, struct kthread_delayed_work * dwork, unsigned long delay)
queue the associated kthread work after a delay.

Parameters

struct kthread_worker * worker target kthread_worker

struct kthread_delayed_work * dwork kthread_delayed_work to queue

unsigned long delay number of jiffies to wait before queuing

Description

If the work has not been pending it starts a timer that will queue the work after the given **delay**. If **delay** is zero, it queues the work immediately.

Return

`false` if the **work** has already been pending. It means that either the timer was running or the work was queued. It returns `true` otherwise.

void **kthread_flush_work**(struct kthread_work * work)
flush a kthread_work

Parameters

struct kthread_work * work work to flush

Description

If **work** is queued or executing, wait for it to finish execution.

bool **kthread_mod_delayed_work**(struct kthread_worker * worker, struct kthread_delayed_work * dwork, unsigned long delay)
modify delay of or queue a kthread delayed work

Parameters

struct kthread_worker * worker kthread worker to use

struct kthread_delayed_work * dwork kthread delayed work to queue

unsigned long delay number of jiffies to wait before queuing

Description

If **dwork** is idle, equivalent to `kthread_queue_delayed_work()`. Otherwise, modify **dwork**'s timer so that it expires after **delay**. If **delay** is zero, **work** is guaranteed to be queued immediately.

A special case is when the work is being canceled in parallel. It might be caused either by the real `kthread_cancel_delayed_work_sync()` or yet another `kthread_mod_delayed_work()` call. We let the other command win and return `false` here. The caller is supposed to synchronize these operations a reasonable way.

This function is safe to call from any context including IRQ handler. See __kthread_cancel_work() and `kthread_delayed_work_timer_fn()` for details.

Return

`true` if **dwork** was pending and its timer was modified, `false` otherwise.

bool **kthread_cancel_work_sync**(struct kthread_work * work)
cancel a kthread work and wait for it to finish

Parameters

struct kthread_work * work the kthread work to cancel

Description

Cancel **work** and wait for its execution to finish. This function can be used even if the work re-queues itself. On return from this function, **work** is guaranteed to be not pending or executing on any CPU.

kthread_cancel_work_sync(`delayed_work->work`) must not be used for delayed_work's. Use `kthread_cancel_delayed_work_sync()` instead.

The caller must ensure that the worker on which **work** was last queued can't be destroyed before this function returns.

Return

`true` if **work** was pending, `false` otherwise.

bool **kthread_cancel_delayed_work_sync**(struct kthread_delayed_work * dwork)
cancel a kthread delayed work and wait for it to finish.

Parameters

struct kthread_delayed_work * dwork the kthread delayed work to cancel

Description

This is `kthread_cancel_work_sync()` for delayed works.

Return

`true` if **dwork** was pending, `false` otherwise.

void **kthread_flush_worker**(struct kthread_worker * worker)
flush all current works on a kthread_worker

Parameters

struct kthread_worker * worker worker to flush

Description

Wait until all currently executing or pending works on **worker** are finished.

void **kthread_destroy_worker**(struct kthread_worker * worker)
destroy a kthread worker

Parameters

struct kthread_worker * worker worker to be destroyed

Description

Flush and destroy **worker**. The simple flush is enough because the kthread worker API is used only in trivial scenarios. There are no multi-step state machines needed.

void **kthread_use_mm**(struct mm_struct * mm)
make the calling kthread operate on an address space

Parameters

struct mm_struct * mm address space to operate on

void **kthread_unuse_mm**(struct mm_struct * mm)
reverse the effect of `kthread_use_mm()`

Parameters

struct mm_struct * mm address space to operate on

void **kthread_associate_blkcg**(struct cgroup_subsys_state * css)
associate blkcg to current kthread

Parameters

struct cgroup_subsys_state * css the cgroup info

Description

Current thread must be a kthread. The thread is running jobs on behalf of other threads. In some cases, we expect the jobs attach cgroup info of original threads instead of that of current thread. This function stores original thread's cgroup info in current kthread context for later retrieval.

struct cgroup_subsys_state * **kthread_blkcg**(void)
get associated blkcg css of current kthread

Parameters

void no arguments

Description

Current thread must be a kthread.

2.8 Reference counting

struct **refcount_struct**
variant of atomic_t specialized for reference counts

Definition

```
struct refcount_struct {
  atomic_t refs;
};
```

Members

refs atomic_t counter field

Description

The counter saturates at REFCOUNT_SATURATED and will not move once there. This avoids wrapping the counter and causing 'spurious' use-after-free bugs.

void **refcount_set**(refcount_t * r, int n)
set a refcount's value

Parameters

refcount_t * r the refcount

int n value to which the refcount will be set

unsigned int **refcount_read**(const refcount_t * r)
get a refcount’s value

Parameters

const refcount_t * r the refcount

Return

the refcount’s value

bool **refcount_add_not_zero**(int i, refcount_t * r)
add a value to a refcount unless it is 0

Parameters

int i the value to add to the refcount

refcount_t * r the refcount

Description

Will saturate at REFCOUNT_SATURATED and WARN.

Provides no memory ordering, it is assumed the caller has guaranteed the object memory to be stable (RCU, etc.). It does provide a control dependency and thereby orders future stores. See the comment on top.

Use of this function is not recommended for the normal reference counting use case in which references are taken and released one at a time. In these cases, `refcount_inc()`, or one of its variants, should instead be used to increment a reference count.

Return

false if the passed refcount is 0, true otherwise

void **refcount_add**(int i, refcount_t * r)
add a value to a refcount

Parameters

int i the value to add to the refcount

refcount_t * r the refcount

Description

Similar to atomic_add(), but will saturate at REFCOUNT_SATURATED and WARN.

Provides no memory ordering, it is assumed the caller has guaranteed the object memory to be stable (RCU, etc.). It does provide a control dependency and thereby orders future stores. See the comment on top.

Use of this function is not recommended for the normal reference counting use case in which references are taken and released one at a time. In these cases, `refcount_inc()`, or one of its variants, should instead be used to increment a reference count.

bool **refcount_inc_not_zero**(refcount_t * r)
increment a refcount unless it is 0

Parameters

refcount_t * r the refcount to increment

Description

Similar to atomic_inc_not_zero(), but will saturate at REFCOUNT_SATURATED and WARN.

Provides no memory ordering, it is assumed the caller has guaranteed the object memory to be stable (RCU, etc.). It does provide a control dependency and thereby orders future stores. See the comment on top.

Return

true if the increment was successful, false otherwise

void **refcount_inc**(refcount_t * r)
increment a refcount

Parameters

refcount_t * r the refcount to increment

Description

Similar to atomic_inc(), but will saturate at REFCOUNT_SATURATED and WARN.

Provides no memory ordering, it is assumed the caller already has a reference on the object.

Will WARN if the refcount is 0, as this represents a possible use-after-free condition.

bool **refcount_sub_and_test**(int i, refcount_t * r)
subtract from a refcount and test if it is 0

Parameters

int i amount to subtract from the refcount

refcount_t * r the refcount

Description

Similar to atomic_dec_and_test(), but it will WARN, return false and ultimately leak on underflow and will fail to decrement when saturated at REFCOUNT_SATURATED.

Provides release memory ordering, such that prior loads and stores are done before, and provides an acquire ordering on success such that free() must come after.

Use of this function is not recommended for the normal reference counting use case in which references are taken and released one at a time. In these cases, `refcount_dec()`, or one of its variants, should instead be used to decrement a reference count.

Return

true if the resulting refcount is 0, false otherwise

bool **refcount_dec_and_test**(refcount_t * r)
decrement a refcount and test if it is 0

Parameters

refcount_t * r the refcount

Description

Similar to atomic_dec_and_test(), it will WARN on underflow and fail to decrement when saturated at REFCOUNT_SATURATED.

Provides release memory ordering, such that prior loads and stores are done before, and provides an acquire ordering on success such that free() must come after.

Return

true if the resulting refcount is 0, false otherwise

void **refcount_dec**(refcount_t * r)
decrement a refcount

Parameters

refcount_t * r the refcount

Description

Similar to atomic_dec(), it will WARN on underflow and fail to decrement when saturated at REFCOUNT_SATURATED.

Provides release memory ordering, such that prior loads and stores are done before.

bool **refcount_dec_if_one**(refcount_t * r)
decrement a refcount if it is 1

Parameters

refcount_t * r the refcount

Description

No atomic_t counterpart, it attempts a 1 -> 0 transition and returns the success thereof.

Like all decrement operations, it provides release memory order and provides a control dependency.

It can be used like a try-delete operator; this explicit case is provided and not cmpxchg in generic, because that would allow implementing unsafe operations.

Return

true if the resulting refcount is 0, false otherwise

bool **refcount_dec_not_one**(refcount_t * r)
decrement a refcount if it is not 1

Parameters

refcount_t * r the refcount

Description

No atomic_t counterpart, it decrements unless the value is 1, in which case it will return false.

Was often done like: atomic_add_unless(var, -1, 1)

Return

true if the decrement operation was successful, false otherwise

bool **refcount_dec_and_mutex_lock**(refcount_t * r, struct mutex * lock)
return holding mutex if able to decrement refcount to 0

Parameters

refcount_t * r the refcount

struct mutex * lock the mutex to be locked

Description

Similar to atomic_dec_and_mutex_lock(), it will WARN on underflow and fail to decrement when saturated at REFCOUNT_SATURATED.

Provides release memory ordering, such that prior loads and stores are done before, and provides a control dependency such that free() must come after. See the comment on top.

Return

true and hold mutex if able to decrement refcount to 0, false otherwise

bool **refcount_dec_and_lock**(refcount_t * r, spinlock_t * lock)
return holding spinlock if able to decrement refcount to 0

Parameters

refcount_t * r the refcount

spinlock_t * lock the spinlock to be locked

Description

Similar to atomic_dec_and_lock(), it will WARN on underflow and fail to decrement when saturated at REFCOUNT_SATURATED.

Provides release memory ordering, such that prior loads and stores are done before, and provides a control dependency such that free() must come after. See the comment on top.

Return

true and hold spinlock if able to decrement refcount to 0, false otherwise

bool **refcount_dec_and_lock_irqsave**(refcount_t * r, spinlock_t * lock, unsigned long * flags)
return holding spinlock with disabled interrupts if able to decrement refcount to 0

Parameters

refcount_t * r the refcount

spinlock_t * lock the spinlock to be locked

unsigned long * flags saved IRQ-flags if the is acquired

Description

Same as `refcount_dec_and_lock()` above except that the spinlock is acquired with disabled interupts.

Return

true and hold spinlock if able to decrement refcount to 0, false otherwise

2.9 Atomics

int **arch_atomic_read**(const atomic_t * v)
read atomic variable

Parameters

const atomic_t * v pointer of type atomic_t

Description

Atomically reads the value of **v**.

void **arch_atomic_set**(atomic_t * v, int i)
set atomic variable

Parameters

atomic_t * v pointer of type atomic_t

int i required value

Description

Atomically sets the value of **v** to **i**.

void **arch_atomic_add**(int i, atomic_t * v)
add integer to atomic variable

Parameters

int i integer value to add

atomic_t * v pointer of type atomic_t

Description

Atomically adds **i** to **v**.

void **arch_atomic_sub**(int i, atomic_t * v)
subtract integer from atomic variable

Parameters

int i integer value to subtract

atomic_t * v pointer of type atomic_t

Description

Atomically subtracts **i** from **v**.

bool **arch_atomic_sub_and_test**(int i, atomic_t * v)
subtract value from variable and test result

Parameters

int i integer value to subtract

atomic_t * v pointer of type atomic_t

Description

Atomically subtracts **i** from **v** and returns true if the result is zero, or false for all other cases.

void **arch_atomic_inc**(atomic_t * v)
increment atomic variable

Parameters

atomic_t * v pointer of type atomic_t

Description

Atomically increments **v** by 1.

void **arch_atomic_dec**(atomic_t * v)
decrement atomic variable

Parameters

atomic_t * v pointer of type atomic_t

Description

Atomically decrements **v** by 1.

bool **arch_atomic_dec_and_test**(atomic_t * v)
decrement and test

Parameters

atomic_t * v pointer of type atomic_t

Description

Atomically decrements **v** by 1 and returns true if the result is 0, or false for all other cases.

bool **arch_atomic_inc_and_test**(atomic_t * v)
increment and test

Parameters

atomic_t * v pointer of type atomic_t

Description

Atomically increments **v** by 1 and returns true if the result is zero, or false for all other cases.

bool **arch_atomic_add_negative**(int i, atomic_t * v)
add and test if negative

Parameters

int i integer value to add

atomic_t * v pointer of type atomic_t

Description

Atomically adds **i** to **v** and returns true if the result is negative, or false when result is greater than or equal to zero.

int **arch_atomic_add_return**(int i, atomic_t * v)
add integer and return

Parameters

int i integer value to add

atomic_t * v pointer of type atomic_t

Description

Atomically adds **i** to **v** and returns **i** + **v**

int **arch_atomic_sub_return**(int i, atomic_t * v)
subtract integer and return

Parameters

int i integer value to subtract

atomic_t * v pointer of type atomic_t

Description

Atomically subtracts **i** from **v** and returns **v** - **i**

2.10 Kernel objects manipulation

char * **kobject_get_path**(struct kobject * kobj, gfp_t gfp_mask)
Allocate memory and fill in the path for **kobj**.

Parameters

struct kobject * kobj kobject in question, with which to build the path

gfp_t gfp_mask the allocation type used to allocate the path

Return

The newly allocated memory, caller must free with kfree().

int **kobject_set_name**(struct kobject * kobj, const char * fmt, ...)
Set the name of a kobject.

Parameters

struct kobject * kobj struct kobject to set the name of

const char * fmt format string used to build the name

... variable arguments

Description

This sets the name of the kobject. If you have already added the kobject to the system, you must call `kobject_rename()` in order to change the name of the kobject.

void **kobject_init**(struct kobject * kobj, struct kobj_type * ktype)
Initialize a kobject structure.

Parameters

struct kobject * kobj pointer to the kobject to initialize

struct kobj_type * ktype pointer to the ktype for this kobject.

Description

This function will properly initialize a kobject such that it can then be passed to the `kobject_add()` call.

After this function is called, the kobject MUST be cleaned up by a call to `kobject_put()`, not by a call to kfree directly to ensure that all of the memory is cleaned up properly.

int **kobject_add**(struct kobject * kobj, struct kobject * parent, const char * fmt, ...)
The main kobject add function.

Parameters

struct kobject * kobj the kobject to add

struct kobject * parent pointer to the parent of the kobject.

const char * fmt format to name the kobject with.

... variable arguments

Description

The kobject name is set and added to the kobject hierarchy in this function.

If **parent** is set, then the parent of the **kobj** will be set to it. If **parent** is NULL, then the parent of the **kobj** will be set to the kobject associated with the kset assigned to this kobject. If no kset is assigned to the kobject, then the kobject will be located in the root of the sysfs tree.

Note, no "add" uevent will be created with this call, the caller should set up all of the necessary sysfs files for the object and then call kobject_uevent() with the UEVENT_ADD parameter to ensure that userspace is properly notified of this kobject's creation.

Return

If this function returns an error, kobject_put() must be called to properly clean up the memory associated with the object. Under no instance should the kobject that is passed to this function be directly freed with a call to kfree(), that can leak memory.

If this function returns success, `kobject_put()` must also be called in order to properly clean up the memory associated with the object.

In short, once this function is called, `kobject_put()` MUST be called when the use of the object is finished in order to properly free everything.

int **kobject_init_and_add**(struct kobject * kobj, struct kobj_type * ktype, struct kobject * parent, const char * fmt, ...)
Initialize a kobject structure and add it to the kobject hierarchy.

Parameters

struct kobject * kobj pointer to the kobject to initialize

struct kobj_type * ktype pointer to the ktype for this kobject.

struct kobject * parent pointer to the parent of this kobject.

const char * fmt the name of the kobject.

... variable arguments

Description

This function combines the call to `kobject_init()` and `kobject_add()`.

If this function returns an error, `kobject_put()` must be called to properly clean up the memory associated with the object. This is the same type of error handling after a call to `kobject_add()` and kobject lifetime rules are the same here.

int **kobject_rename**(struct kobject * kobj, const char * new_name)
Change the name of an object.

Parameters

struct kobject * kobj object in question.

const char * new_name object' s new name

Description

It is the responsibility of the caller to provide mutual exclusion between two different calls of kobject_rename on the same kobject and to ensure that new_name is valid and won' t conflict with other kobjects.

int **kobject_move**(struct kobject * kobj, struct kobject * new_parent)
Move object to another parent.

Parameters

struct kobject * kobj object in question.

struct kobject * new_parent object' s new parent (can be NULL)

void **kobject_del**(struct kobject * kobj)
Unlink kobject from hierarchy.

Parameters

struct kobject * kobj object.

Description

This is the function that should be called to delete an object successfully added via `kobject_add()`.

struct kobject * **kobject_get**(struct kobject * kobj)
Increment refcount for object.

Parameters

struct kobject * kobj object.

void **kobject_put**(struct kobject * kobj)
Decrement refcount for object.

Parameters

struct kobject * kobj object.

Description

Decrement the refcount, and if 0, call kobject_cleanup().

struct kobject * **kobject_create_and_add**(const char * name, struct kobject * parent)
Create a struct kobject dynamically and register it with sysfs.

Parameters

const char * name the name for the kobject

struct kobject * parent the parent kobject of this kobject, if any.

Description

This function creates a kobject structure dynamically and registers it with sysfs. When you are finished with this structure, call `kobject_put()` and the structure will be dynamically freed when it is no longer being used.

If the kobject was not able to be created, NULL will be returned.

int **kset_register**(struct kset * k)
Initialize and add a kset.

Parameters

struct kset * k kset.

void **kset_unregister**(struct kset * k)
Remove a kset.

Parameters

struct kset * k kset.

struct kobject * **kset_find_obj**(struct kset * kset, const char * name)
Search for object in kset.

Parameters

struct kset * kset kset we' re looking in.

const char * name object' s name.

Description

Lock kset via **kset->subsys**, and iterate over **kset->list**, looking for a matching kobject. If matching object is found take a reference and return the object.

struct kset * **kset_create_and_add**(const char * name, const struct kset_uevent_ops * uevent_ops, struct kobject * parent_kobj)
Create a struct kset dynamically and add it to sysfs.

Parameters

const char * name the name for the kset

const struct kset_uevent_ops * uevent_ops a struct kset_uevent_ops for the kset

struct kobject * parent_kobj the parent kobject of this kset, if any.

Description

This function creates a kset structure dynamically and registers it with sysfs. When you are finished with this structure, call `kset_unregister()` and the structure will be dynamically freed when it is no longer being used.

If the kset was not able to be created, NULL will be returned.

2.11 Kernel utility functions

REPEAT_BYTE(x)
repeat the value **x** multiple times as an unsigned long value

Parameters

x value to repeat

NOTE

x is not checked for > 0xff; larger values produce odd results.

ARRAY_SIZE(arr)
get the number of elements in array **arr**

Parameters

arr array to be sized

round_up(x, y)
round up to next specified power of 2

Parameters

x the value to round

y multiple to round up to (must be a power of 2)

Description

Rounds **x** up to next multiple of **y** (which must be a power of 2). To perform arbitrary rounding up, use `roundup()` below.

round_down(x, y)
round down to next specified power of 2

Parameters

x the value to round

y multiple to round down to (must be a power of 2)

Description

Rounds **x** down to next multiple of **y** (which must be a power of 2). To perform arbitrary rounding down, use `rounddown()` below.

roundup(x, y)
round up to the next specified multiple

Parameters

x the value to up

y multiple to round up to

Description

Rounds **x** up to next multiple of **y**. If **y** will always be a power of 2, consider using the faster `round_up()`.

rounddown(x, y)
round down to next specified multiple

Parameters

x the value to round

y multiple to round down to

Description

Rounds **x** down to next multiple of **y**. If **y** will always be a power of 2, consider using the faster `round_down()`.

upper_32_bits(n)
return bits 32-63 of a number

Parameters

n the number we' re accessing

Description

A basic shift-right of a 64- or 32-bit quantity. Use this to suppress the "right shift count >= width of type" warning when that quantity is 32-bits.

lower_32_bits(n)
return bits 0-31 of a number

Parameters

n the number we' re accessing

might_sleep()
annotation for functions that can sleep

Parameters

Description

this macro will print a stack trace if it is executed in an atomic context (spinlock, irq-handler, ⋯). Additional sections where blocking is not allowed can be annotated with `non_block_start()` and `non_block_end()` pairs.

This is a useful debugging help to be able to catch problems early and not be bitten later when the calling function happens to sleep when it is not supposed to.

cant_sleep()
annotation for functions that cannot sleep

Parameters

Description

this macro will print a stack trace if it is executed with preemption enabled

non_block_start()
annotate the start of section where sleeping is prohibited

Parameters

Description

This is on behalf of the oom reaper, specifically when it is calling the mmu notifiers. The problem is that if the notifier were to block on, for example, mutex_lock() and if the process which holds that mutex were to perform a sleeping memory allocation, the oom reaper is now blocked on completion of that memory allocation. Other blocking calls like `wait_event()` pose similar issues.

non_block_end()
annotate the end of section where sleeping is prohibited

Parameters

Description

Closes a section opened by `non_block_start()`.

abs(x)
return absolute value of an argument

Parameters

x the value. If it is unsigned type, it is converted to signed type first. char is treated as if it was signed (regardless of whether it really is) but the macro's return type is preserved as char.

Return

an absolute value of x.

u32 **reciprocal_scale**(u32 val, u32 ep_ro)
"scale" a value into range [0, ep_ro)

Parameters

u32 val value

u32 ep_ro right open interval endpoint

Description

Perform a "reciprocal multiplication" in order to "scale" a value into range [0, **ep_ro**), where the upper interval endpoint is right-open. This is useful, e.g. for accessing a index of an array containing **ep_ro** elements, for example. Think of it as sort of modulus, only that the result isn't that of modulo. ;) Note that if initial input is a small value, then result will return 0.

Return

a result based on **val** in interval [0, **ep_ro**).

int **kstrtoul**(const char * s, unsigned int base, unsigned long * res)
convert a string to an unsigned long

Parameters

const char * s The start of the string. The string must be null-terminated, and may also include a single newline before its terminating null. The first character may also be a plus sign, but not a minus sign.

unsigned int base The number base to use. The maximum supported base is 16. If base is given as 0, then the base of the string is automatically detected with the conventional semantics - If it begins with 0x the number will be parsed as a hexadecimal (case insensitive), if it otherwise begins with 0, it will be parsed as an octal number. Otherwise it will be parsed as a decimal.

unsigned long * res Where to write the result of the conversion on success.

Description

Returns 0 on success, -ERANGE on overflow and -EINVAL on parsing error. Used as a replacement for the simple_strtoull. Return code must be checked.

int **kstrtol**(const char * s, unsigned int base, long * res)
convert a string to a long

Parameters

const char * s The start of the string. The string must be null-terminated, and may also include a single newline before its terminating null. The first character may also be a plus sign or a minus sign.

unsigned int base The number base to use. The maximum supported base is 16. If base is given as 0, then the base of the string is automatically detected with the conventional semantics - If it begins with 0x the number will be parsed as a hexadecimal (case insensitive), if it otherwise begins with 0, it will be parsed as an octal number. Otherwise it will be parsed as a decimal.

long * res Where to write the result of the conversion on success.

Description

Returns 0 on success, -ERANGE on overflow and -EINVAL on parsing error. Used as a replacement for the simple_strtoull. Return code must be checked.

trace_printk(fmt, ⋯)
printf formatting in the ftrace buffer

Parameters

fmt the printf format for printing

... variable arguments

Note

__trace_printk is an internal function for trace_printk() and the **ip** is passed in via the `trace_printk()` macro.

Description

This function allows a kernel developer to debug fast path sections that printk is not appropriate for. By scattering in various printk like tracing in the code, a developer can quickly see where problems are occurring.

This is intended as a debugging tool for the developer only. Please refrain from leaving trace_printks scattered around in your code. (Extra memory is used for special buffers that are allocated when `trace_printk()` is used.)

A little optimization trick is done here. If there's only one argument, there's no need to scan the string for printf formats. The `trace_puts()` will suffice. But how can we take advantage of using `trace_puts()` when `trace_printk()` has only one argument? By stringifying the args and checking the size we can tell whether or not there are args. __stringify((__VA_ARGS__)) will turn into "()0" with a size of 3 when there are no args, anything else will be bigger. All we need to do is define a string to this, and then take its size and compare to 3. If it's bigger, use do_trace_printk() otherwise, optimize it to `trace_puts()`. Then just let gcc optimize the rest.

trace_puts(str)
write a string into the ftrace buffer

Parameters

str the string to record

Note

__trace_bputs is an internal function for trace_puts and the **ip** is passed in via the trace_puts macro.

Description

This is similar to `trace_printk()` but is made for those really fast paths that a developer wants the least amount of "Heisenbug" effects, where the processing of the print format is still too much.

This function allows a kernel developer to debug fast path sections that printk is not appropriate for. By scattering in various printk like tracing in the code, a developer can quickly see where problems are occurring.

This is intended as a debugging tool for the developer only. Please refrain from leaving trace_puts scattered around in your code. (Extra memory is used for special buffers that are allocated when `trace_puts()` is used.)

Return

0 if nothing was written, positive # if string was. (1 when __trace_bputs is used, strlen(str) when __trace_puts is used)

min(x, y)
return minimum of two values of the same or compatible types

Parameters

x first value

y second value

max(x, y)
return maximum of two values of the same or compatible types

Parameters

x first value

y second value

min3(x, y, z)
return minimum of three values

Parameters

x first value

y second value

z third value

max3(x, y, z)
return maximum of three values

Parameters

x first value

y second value

z third value

min_not_zero(x, y)
return the minimum that is _not_ zero, unless both are zero

Parameters

x value1

y value2

clamp(val, lo, hi)
return a value clamped to a given range with strict typechecking

Parameters

val current value

lo lowest allowable value

hi highest allowable value

Description

This macro does strict typechecking of **lo/hi** to make sure they are of the same type as **val**. See the unnecessary pointer comparisons.

min_t(type, x, y)
return minimum of two values, using the specified type

Parameters

type data type to use

x first value

y second value

max_t(type, x, y)
return maximum of two values, using the specified type

Parameters

type data type to use

x first value

y second value

clamp_t(type, val, lo, hi)
return a value clamped to a given range using a given type

Parameters

type the type of variable to use

val current value

lo minimum allowable value

hi maximum allowable value

Description

This macro does no typechecking and uses temporary variables of type **type** to make all the comparisons.

clamp_val(val, lo, hi)
return a value clamped to a given range using val' s type

Parameters

val current value

lo minimum allowable value

hi maximum allowable value

Description

This macro does no typechecking and uses temporary variables of whatever type the input argument **val** is. This is useful when **val** is an unsigned type and **lo** and **hi** are literals that will otherwise be assigned a signed integer type.

swap(a, b)
swap values of **a** and **b**

Parameters

a first value

b second value

container_of(ptr, type, member)
cast a member of a structure out to the containing structure

Parameters

ptr the pointer to the member.

type the type of the container struct this is embedded in.

member the name of the member within the struct.

container_of_safe(ptr, type, member)
cast a member of a structure out to the containing structure

Parameters

ptr the pointer to the member.

type the type of the container struct this is embedded in.

member the name of the member within the struct.

Description

If IS_ERR_OR_NULL(ptr), ptr is returned unchanged.

__visible int **printk**(const char * fmt, ...)
print a kernel message

Parameters

const char * fmt format string

... variable arguments

Description

This is `printk()`. It can be called from any context. We want it to work.

We try to grab the console_lock. If we succeed, it' s easy - we log the output and call the console drivers. If we fail to get the semaphore, we place the output into the log buffer and return. The current holder of the console_sem will notice the new output in `console_unlock()`; and will send it to the consoles before releasing the lock.

One effect of this deferred printing is that code which calls `printk()` and then changes console_loglevel may break. This is because console_loglevel is inspected when the actual printing occurs.

See also: printf(3)

See the vsnprintf() documentation for format string extensions over C99.

void **console_lock**(void)
lock the console system for exclusive use.

Parameters

void no arguments

Description

Acquires a lock which guarantees that the caller has exclusive access to the console system and the console_drivers list.

Can sleep, returns nothing.

int **console_trylock**(void)
try to lock the console system for exclusive use.

Parameters

void no arguments

Description

Try to acquire a lock which guarantees that the caller has exclusive access to the console system and the console_drivers list.

returns 1 on success, and 0 on failure to acquire the lock.

void **console_unlock**(void)
unlock the console system

Parameters

void no arguments

Description

Releases the console_lock which the caller holds on the console system and the console driver list.

While the console_lock was held, console output may have been buffered by `printk()`. If this is the case, `console_unlock();` emits the output prior to releasing the lock.

If there is output waiting, we wake /dev/kmsg and syslog() users.

`console_unlock();` may be called from any context.

void **console_conditional_schedule**(void)
yield the CPU if required

Parameters

void no arguments

Description

If the console code is currently allowed to sleep, and if this CPU should yield the CPU to another task, do so here.

Must be called within `console_lock();`.

bool **printk_timed_ratelimit**(unsigned long * caller_jiffies, unsigned int interval_msecs)
caller-controlled printk ratelimiting

Parameters

unsigned long * caller_jiffies pointer to caller's state

unsigned int interval_msecs minimum interval between prints

Description

`printk_timed_ratelimit()` returns true if more than **interval_msecs** milliseconds have elapsed since the last time `printk_timed_ratelimit()` returned true.

int **kmsg_dump_register**(struct kmsg_dumper * dumper)
register a kernel log dumper.

Parameters

struct kmsg_dumper * dumper pointer to the kmsg_dumper structure

Description

Adds a kernel log dumper to the system. The dump callback in the structure will be called when the kernel oopses or panics and must be set. Returns zero on success and `-EINVAL` or `-EBUSY` otherwise.

int **kmsg_dump_unregister**(struct kmsg_dumper * dumper)
unregister a kmsg dumper.

Parameters

struct kmsg_dumper * dumper pointer to the kmsg_dumper structure

Description

Removes a dump device from the system. Returns zero on success and -EINVAL otherwise.

bool **kmsg_dump_get_line**(struct kmsg_dumper * dumper, bool syslog, char * line, size_t size, size_t * len)
retrieve one kmsg log line

Parameters

struct kmsg_dumper * dumper registered kmsg dumper

bool syslog include the “<4>” prefixes

char * line buffer to copy the line to

size_t size maximum size of the buffer

size_t * len length of line placed into buffer

Description

Start at the beginning of the kmsg buffer, with the oldest kmsg record, and copy one record into the provided buffer.

Consecutive calls will return the next available record moving towards the end of the buffer with the youngest messages.

A return value of FALSE indicates that there are no more records to read.

bool **kmsg_dump_get_buffer**(struct kmsg_dumper * dumper, bool syslog, char * buf, size_t size, size_t * len)
copy kmsg log lines

Parameters

struct kmsg_dumper * dumper registered kmsg dumper

bool syslog include the “<4>” prefixes

char * buf buffer to copy the line to

size_t size maximum size of the buffer

size_t * len length of line placed into buffer

Description

Start at the end of the kmsg buffer and fill the provided buffer with as many of the the youngest kmsg records that fit into it. If the buffer is large enough, all available kmsg records will be copied with a single call.

Consecutive calls will fill the buffer with the next block of available older records, not including the earlier retrieved ones.

A return value of FALSE indicates that there are no more records to read.

void **kmsg_dump_rewind**(struct kmsg_dumper * dumper)
reset the iterator

Parameters

struct kmsg_dumper * dumper registered kmsg dumper

Description

Reset the dumper's iterator so that `kmsg_dump_get_line()` and `kmsg_dump_get_buffer()` can be called again and used multiple times within the same dumper.dump() callback.

void **panic**(const char * fmt, ...)
halt the system

Parameters

const char * fmt The text string to print

Display a message, then perform cleanups.

This function never returns.

... variable arguments

void **add_taint**(unsigned flag, enum lockdep_ok lockdep_ok)

Parameters

unsigned flag one of the TAINT_* constants.

enum lockdep_ok lockdep_ok whether lock debugging is still OK.

Description

If something bad has gone wrong, you'll want **lockdebug_ok** = false, but for some noteworthtt-but-not-corrupting cases, it can be set to true.

bool **rcu_is_watching**(void)
see if RCU thinks that the current CPU is not idle

Parameters

void no arguments

Description

Return true if RCU is watching the running CPU, which means that this CPU can safely enter RCU read-side critical sections. In other words, if the current CPU is not in its idle loop or is in an interrupt or NMI handler, return true.

void **call_rcu**(struct rcu_head * head, rcu_callback_t func)
Queue an RCU callback for invocation after a grace period.

Parameters

struct rcu_head * head structure to be used for queueing the RCU updates.

rcu_callback_t func actual callback function to be invoked after the grace period

Description

The callback function will be invoked some time after a full grace period elapses, in other words after all pre-existing RCU read-side critical sections have completed. However, the callback function might well execute concurrently with RCU read-side critical sections that started after `call_rcu()` was invoked. RCU read-side critical sections are delimited by rcu_read_lock() and rcu_read_unlock(), and may be nested. In addition, regions of code across which interrupts, preemption, or softirqs have been disabled also serve as RCU read-side critical sections. This includes hardware interrupt handlers, softirq handlers, and NMI handlers.

Note that all CPUs must agree that the grace period extended beyond all pre-existing RCU read-side critical section. On systems with more than one CPU, this means that when "func()" is invoked, each CPU is guaranteed to have executed a full memory barrier since the end of its last RCU read-side critical section whose beginning preceded the call to `call_rcu()`. It also means that each CPU executing an RCU read-side critical section that continues beyond the start of "func()" must have executed a memory barrier after the `call_rcu()` but before the beginning of that RCU read-side critical section. Note that these guarantees include CPUs that are offline, idle, or executing in user mode, as well as CPUs that are executing in the kernel.

Furthermore, if CPU A invoked `call_rcu()` and CPU B invoked the resulting RCU callback function "func()" , then both CPU A and CPU B are guaranteed to execute a full memory barrier during the time interval between the call to `call_rcu()` and the invocation of "func()" – even if CPU A and CPU B are the same CPU (but again only if the system has more than one CPU).

void **`synchronize_rcu`**(void)
wait until a grace period has elapsed.

Parameters

`void` no arguments

Description

Control will return to the caller some time after a full grace period has elapsed, in other words after all currently executing RCU read-side critical sections have completed. Note, however, that upon return from `synchronize_rcu()`, the caller might well be executing concurrently with new RCU read-side critical sections that began while `synchronize_rcu()` was waiting. RCU read-side critical sections are delimited by rcu_read_lock() and rcu_read_unlock(), and may be nested. In addition, regions of code across which interrupts, preemption, or softirqs have been disabled also serve as RCU read-side critical sections. This includes hardware interrupt handlers, softirq handlers, and NMI handlers.

Note that this guarantee implies further memory-ordering guarantees. On systems with more than one CPU, when `synchronize_rcu()` returns, each CPU is guaranteed to have executed a full memory barrier since the end of its last RCU read-side critical section whose beginning preceded the call to `synchronize_rcu()`. In addition, each CPU having an RCU read-side critical section that extends beyond the return from `synchronize_rcu()` is guaranteed to have executed a full memory barrier after the beginning of `synchronize_rcu()` and before the beginning of that RCU read-side critical section. Note that these guarantees include CPUs that are offline, idle, or executing in user mode, as well as CPUs that are executing in the kernel.

Furthermore, if CPU A invoked `synchronize_rcu()`, which returned to its caller on CPU B, then both CPU A and CPU B are guaranteed to have executed a full memory barrier during the execution of `synchronize_rcu()` – even if CPU A and CPU B are the same CPU (but again only if the system has more than one CPU).

unsigned long **get_state_synchronize_rcu**(void)
Snapshot current RCU state

Parameters

void no arguments

Description

Returns a cookie that is used by a later call to `cond_synchronize_rcu()` to determine whether or not a full grace period has elapsed in the meantime.

void **cond_synchronize_rcu**(unsigned long oldstate)
Conditionally wait for an RCU grace period

Parameters

unsigned long oldstate return value from earlier call to `get_state_synchronize_rcu()`

Description

If a full RCU grace period has elapsed since the earlier call to `get_state_synchronize_rcu()`, just return. Otherwise, invoke `synchronize_rcu()` to wait for a full grace period.

Yes, this function does not take counter wrap into account. But counter wrap is harmless. If the counter wraps, we have waited for more than 2 billion grace periods (and way more on a 64-bit system!), so waiting for one additional grace period should be just fine.

void **rcu_barrier**(void)
Wait until all in-flight `call_rcu()` callbacks complete.

Parameters

void no arguments

Description

Note that this primitive does not necessarily wait for an RCU grace period to complete. For example, if there are no RCU callbacks queued anywhere in the system, then `rcu_barrier()` is within its rights to return immediately, without waiting for anything, much less an RCU grace period.

void **rcu_expedite_gp**(void)
Expedite future RCU grace periods

Parameters

void no arguments

Description

After a call to this function, future calls to `synchronize_rcu()` and friends act as the corresponding synchronize_rcu_expedited() function had instead been called.

void **rcu_unexpedite_gp**(void)
Cancel prior `rcu_expedite_gp()` invocation

Parameters

void no arguments

Description

Undo a prior call to `rcu_expedite_gp()`. If all prior calls to `rcu_expedite_gp()` are undone by a subsequent call to `rcu_unexpedite_gp()`, and if the rcu_expedited sysfs/boot parameter is not set, then all subsequent calls to `synchronize_rcu()` and friends will return to their normal non-expedited behavior.

int **rcu_read_lock_held**(void)
might we be in RCU read-side critical section?

Parameters

void no arguments

Description

If CONFIG_DEBUG_LOCK_ALLOC is selected, returns nonzero iff in an RCU read-side critical section. In absence of CONFIG_DEBUG_LOCK_ALLOC, this assumes we are in an RCU read-side critical section unless it can prove otherwise. This is useful for debug checks in functions that require that they be called within an RCU read-side critical section.

Checks debug_lockdep_rcu_enabled() to prevent false positives during boot and while lockdep is disabled.

Note that rcu_read_lock() and the matching rcu_read_unlock() must occur in the same context, for example, it is illegal to invoke rcu_read_unlock() in process context if the matching rcu_read_lock() was invoked from within an irq handler.

Note that rcu_read_lock() is disallowed if the CPU is either idle or offline from an RCU perspective, so check for those as well.

int **rcu_read_lock_bh_held**(void)
might we be in RCU-bh read-side critical section?

Parameters

void no arguments

Description

Check for bottom half being disabled, which covers both the CONFIG_PROVE_RCU and not cases. Note that if someone uses rcu_read_lock_bh(), but then later enables BH, lockdep (if enabled) will show the situation. This is useful for debug checks in functions that require that they be called within an RCU read-side critical section.

Check debug_lockdep_rcu_enabled() to prevent false positives during boot.

Note that rcu_read_lock_bh() is disallowed if the CPU is either idle or offline from an RCU perspective, so check for those as well.

void **wakeme_after_rcu**(struct rcu_head * head)
Callback function to awaken a task after grace period

Parameters

struct rcu_head * head Pointer to rcu_head member within rcu_synchronize structure

Description

Awaken the corresponding task now that a grace period has elapsed.

void **init_rcu_head_on_stack**(struct rcu_head * head)
initialize on-stack rcu_head for debugobjects

Parameters

struct rcu_head * head pointer to rcu_head structure to be initialized

Description

This function informs debugobjects of a new rcu_head structure that has been allocated as an auto variable on the stack. This function is not required for rcu_head structures that are statically defined or that are dynamically allocated on the heap. This function has no effect for !CONFIG_DEBUG_OBJECTS_RCU_HEAD kernel builds.

void **destroy_rcu_head_on_stack**(struct rcu_head * head)
destroy on-stack rcu_head for debugobjects

Parameters

struct rcu_head * head pointer to rcu_head structure to be initialized

Description

This function informs debugobjects that an on-stack rcu_head structure is about to go out of scope. As with `init_rcu_head_on_stack()`, this function is not required for rcu_head structures that are statically defined or that are dynamically allocated on the heap. Also as with `init_rcu_head_on_stack()`, this function has no effect for !CONFIG_DEBUG_OBJECTS_RCU_HEAD kernel builds.

size_t **array_size**(size_t a, size_t b)
Calculate size of 2-dimensional array.

Parameters

size_t a dimension one

size_t b dimension two

Description

Calculates size of 2-dimensional array: **a** * **b**.

Return

number of bytes needed to represent the array or SIZE_MAX on overflow.

size_t **array3_size**(size_t a, size_t b, size_t c)
Calculate size of 3-dimensional array.

Parameters

size_t a dimension one

size_t b dimension two

size_t c dimension three

Description

Calculates size of 3-dimensional array: **a** * **b** * **c**.

Return

number of bytes needed to represent the array or SIZE_MAX on overflow.

struct_size(p, member, count)
Calculate size of structure with trailing array.

Parameters

p Pointer to the structure.

member Name of the array member.

count Number of elements in the array.

Description

Calculates size of memory needed for structure **p** followed by an array of **count** number of **member** elements.

Return

number of bytes needed or SIZE_MAX on overflow.

flex_array_size(p, member, count)
Calculate size of a flexible array member within an enclosing structure.

Parameters

p Pointer to the structure.

member Name of the flexible array member.

count Number of elements in the array.

Description

Calculates size of a flexible array of **count** number of **member** elements, at the end of structure **p**.

Return

number of bytes needed or SIZE_MAX on overflow.

2.12 Device Resource Management

void * **devres_alloc_node**(dr_release_t release, size_t size, gfp_t gfp, int nid)
Allocate device resource data

Parameters

dr_release_t release Release function devres will be associated with

size_t size Allocation size

gfp_t gfp Allocation flags

int nid NUMA node

Description

Allocate devres of **size** bytes. The allocated area is zeroed, then associated with **release**. The returned pointer can be passed to other devres_*() functions.

Return

Pointer to allocated devres on success, NULL on failure.

void **devres_for_each_res**(struct device * dev, dr_release_t release, dr_match_t match, void * match_data, void (*fn)(struct device *, void *, void *), void * data)
Resource iterator

Parameters

struct device * dev Device to iterate resource from

dr_release_t release Look for resources associated with this release function

dr_match_t match Match function (optional)

void * match_data Data for the match function

void (*)(struct device *, void *, void *) fn Function to be called for each matched resource.

void * data Data for **fn**, the 3rd parameter of **fn**

Description

Call **fn** for each devres of **dev** which is associated with **release** and for which **match** returns 1.

Return

void

void **devres_free**(void * res)
Free device resource data

Parameters

void * res Pointer to devres data to free

Description

Free devres created with devres_alloc().

void **devres_add**(struct device * dev, void * res)
Register device resource

Parameters

struct device * dev Device to add resource to

void * res Resource to register

Description

Register devres **res** to **dev**. **res** should have been allocated using devres_alloc(). On driver detach, the associated release function will be invoked and devres will be freed automatically.

void * **devres_find**(struct device * dev, dr_release_t release, dr_match_t match, void * match_data)
Find device resource

Parameters

struct device * dev Device to lookup resource from

dr_release_t release Look for resources associated with this release function

dr_match_t match Match function (optional)

void * match_data Data for the match function

Description

Find the latest devres of **dev** which is associated with **release** and for which **match** returns 1. If **match** is NULL, it' s considered to match all.

Return

Pointer to found devres, NULL if not found.

void * **devres_get**(struct device * dev, void * new_res, dr_match_t match, void * match_data)
Find devres, if non-existent, add one atomically

Parameters

struct device * dev Device to lookup or add devres for

void * new_res Pointer to new initialized devres to add if not found

dr_match_t match Match function (optional)

void * match_data Data for the match function

Description

Find the latest devres of **dev** which has the same release function as **new_res** and for which **match** return 1. If found, **new_res** is freed; otherwise, **new_res** is added atomically.

Return

Pointer to found or added devres.

void * **devres_remove**(struct device * dev, dr_release_t release, dr_match_t match, void * match_data)
Find a device resource and remove it

Parameters

struct device * dev Device to find resource from

dr_release_t release Look for resources associated with this release function

dr_match_t match Match function (optional)

void * match_data Data for the match function

Description

Find the latest devres of **dev** associated with **release** and for which **match** returns 1. If **match** is NULL, it's considered to match all. If found, the resource is removed atomically and returned.

Return

Pointer to removed devres on success, NULL if not found.

int **devres_destroy**(struct device * dev, dr_release_t release, dr_match_t match, void * match_data)
Find a device resource and destroy it

Parameters

struct device * dev Device to find resource from

dr_release_t release Look for resources associated with this release function

dr_match_t match Match function (optional)

void * match_data Data for the match function

Description

Find the latest devres of **dev** associated with **release** and for which **match** returns 1. If **match** is NULL, it's considered to match all. If found, the resource is removed atomically and freed.

Note that the release function for the resource will not be called, only the devres-allocated data will be freed. The caller becomes responsible for freeing any other data.

Return

0 if devres is found and freed, -ENOENT if not found.

int **devres_release**(struct device * dev, dr_release_t release, dr_match_t match, void * match_data)
Find a device resource and destroy it, calling release

Parameters

struct device * dev Device to find resource from

dr_release_t release Look for resources associated with this release function

dr_match_t match Match function (optional)

void * match_data Data for the match function

Description

Find the latest devres of **dev** associated with **release** and for which **match** returns 1. If **match** is NULL, it's considered to match all. If found, the resource is removed atomically, the release function called and the resource freed.

Return

0 if devres is found and freed, -ENOENT if not found.

void * **devres_open_group**(struct device * dev, void * id, gfp_t gfp)
Open a new devres group

Parameters

struct device * dev Device to open devres group for

void * id Separator ID

gfp_t gfp Allocation flags

Description

Open a new devres group for **dev** with **id**. For **id**, using a pointer to an object which won't be used for another group is recommended. If **id** is NULL, address-wise unique ID is created.

Return

ID of the new group, NULL on failure.

void **devres_close_group**(struct device * dev, void * id)
Close a devres group

Parameters

struct device * dev Device to close devres group for

void * id ID of target group, can be NULL

Description

Close the group identified by **id**. If **id** is NULL, the latest open group is selected.

void **devres_remove_group**(struct device * dev, void * id)
Remove a devres group

Parameters

struct device * dev Device to remove group for

void * id ID of target group, can be NULL

Description

Remove the group identified by **id**. If **id** is NULL, the latest open group is selected. Note that removing a group doesn't affect any other resources.

int **devres_release_group**(struct device * dev, void * id)
Release resources in a devres group

Parameters

struct device * dev Device to release group for

void * id ID of target group, can be NULL

Description

Release all resources in the group identified by **id**. If **id** is NULL, the latest open group is selected. The selected group and groups properly nested inside the selected group are removed.

Return

The number of released non-group resources.

int **devm_add_action**(struct device * dev, void (*action)(void *), void * data)
add a custom action to list of managed resources

Parameters

struct device * dev Device that owns the action

void (*)(void *) action Function that should be called

void * data Pointer to data passed to **action** implementation

Description

This adds a custom action to the list of managed resources so that it gets executed as part of standard resource unwinding.

void **devm_remove_action**(struct device * dev, void (*action)(void *), void * data)
removes previously added custom action

Parameters

struct device * dev Device that owns the action

void (*)(void *) action Function implementing the action

void * data Pointer to data passed to **action** implementation

Description

Removes instance of **action** previously added by `devm_add_action()`. Both action and data should match one of the existing entries.

void **devm_release_action**(struct device * dev, void (*action)(void *), void * data)
release previously added custom action

Parameters

struct device * dev Device that owns the action

void (*)(void *) action Function implementing the action

void * data Pointer to data passed to **action** implementation

Description

Releases and removes instance of **action** previously added by `devm_add_action()`. Both action and data should match one of the existing entries.

void * **devm_kmalloc**(struct device * dev, size_t size, gfp_t gfp)
Resource-managed kmalloc

Parameters

struct device * dev Device to allocate memory for

size_t size Allocation size

gfp_t gfp Allocation gfp flags

Description

Managed kmalloc. Memory allocated with this function is automatically freed on driver detach. Like all other devres resources, guaranteed alignment is unsigned long long.

Return

Pointer to allocated memory on success, NULL on failure.

char * **devm_kstrdup**(struct device * dev, const char * s, gfp_t gfp)
Allocate resource managed space and copy an existing string into that.

Parameters

struct device * dev Device to allocate memory for

const char * s the string to duplicate

gfp_t gfp the GFP mask used in the `devm_kmalloc()` call when allocating memory

Return

Pointer to allocated string on success, NULL on failure.

const char * **devm_kstrdup_const**(struct device * dev, const char * s, gfp_t gfp)
resource managed conditional string duplication

Parameters

struct device * dev device for which to duplicate the string

const char * s the string to duplicate

gfp_t gfp the GFP mask used in the kmalloc() call when allocating memory

Description

Strings allocated by devm_kstrdup_const will be automatically freed when the associated device is detached.

Return

Source string if it is in .rodata section otherwise it falls back to devm_kstrdup.

char * **devm_kvasprintf**(struct device * dev, gfp_t gfp, const char * fmt, va_list ap)
Allocate resource managed space and format a string into that.

Parameters

struct device * dev Device to allocate memory for

gfp_t gfp the GFP mask used in the `devm_kmalloc()` call when allocating memory

const char * fmt The printf()-style format string

va_list ap Arguments for the format string

Return

Pointer to allocated string on success, NULL on failure.

char * **devm_kasprintf**(struct device * dev, gfp_t gfp, const char * fmt, ...)
Allocate resource managed space and format a string into that.

Parameters

struct device * dev Device to allocate memory for

gfp_t gfp the GFP mask used in the `devm_kmalloc()` call when allocating memory

const char * fmt The printf()-style format string

... Arguments for the format string

Return

Pointer to allocated string on success, NULL on failure.

void **devm_kfree**(struct device * dev, const void * p)
Resource-managed kfree

Parameters

struct device * dev Device this memory belongs to

const void * p Memory to free

Description

Free memory allocated with `devm_kmalloc()`.

void * **devm_kmemdup**(struct device * dev, const void * src, size_t len, gfp_t gfp)
Resource-managed kmemdup

Parameters

struct device * dev Device this memory belongs to

const void * src Memory region to duplicate

size_t len Memory region length

gfp_t gfp GFP mask to use

Description

Duplicate region of a memory using resource managed kmalloc

unsigned long **devm_get_free_pages**(struct device * dev, gfp_t gfp_mask, unsigned int order)
Resource-managed __get_free_pages

Parameters

struct device * dev Device to allocate memory for

gfp_t gfp_mask Allocation gfp flags

unsigned int order Allocation size is (1 << order) pages

Description

Managed get_free_pages. Memory allocated with this function is automatically freed on driver detach.

Return

Address of allocated memory on success, 0 on failure.

void **devm_free_pages**(struct device * dev, unsigned long addr)
Resource-managed free_pages

Parameters

struct device * dev Device this memory belongs to

unsigned long addr Memory to free

Description

Free memory allocated with `devm_get_free_pages()`. Unlike free_pages, there is no need to supply the **order**.

void __percpu * **__devm_alloc_percpu**(struct device * dev, size_t size, size_t align)
Resource-managed alloc_percpu

Parameters

struct device * dev Device to allocate per-cpu memory for

size_t size Size of per-cpu memory to allocate

size_t align Alignment of per-cpu memory to allocate

Description

Managed alloc_percpu. Per-cpu memory allocated with this function is automatically freed on driver detach.

Return

Pointer to allocated memory on success, NULL on failure.

void **devm_free_percpu**(struct device * dev, void __percpu * pdata)
Resource-managed free_percpu

Parameters

struct device * dev Device this memory belongs to

void __percpu * pdata Per-cpu memory to free

Description

Free memory allocated with `devm_alloc_percpu()`.

CHAPTER

THREE

DEVICE DRIVERS INFRASTRUCTURE

3.1 The Basic Device Driver-Model Structures

struct **subsys_interface**
interfaces to device functions

Definition

```
struct subsys_interface {
  const char *name;
  struct bus_type *subsys;
  struct list_head node;
  int (*add_dev)(struct device *dev, struct subsys_interface *sif);
  void (*remove_dev)(struct device *dev, struct subsys_interface *sif);
};
```

Members

name name of the device function

subsys subsytem of the devices to attach to

node the list of functions registered at the subsystem

add_dev device hookup to device function handler

remove_dev device hookup to device function handler

Description

Simple interfaces attached to a subsystem. Multiple interfaces can attach to a subsystem and its devices. Unlike drivers, they do not exclusively claim or control devices. Interfaces usually represent a specific functionality of a subsystem/class of devices.

devm_alloc_percpu(dev, type)
Resource-managed alloc_percpu

Parameters

dev Device to allocate per-cpu memory for

type Type to allocate per-cpu memory for

Description

Managed alloc_percpu. Per-cpu memory allocated with this function is automatically freed on driver detach.

Return

Pointer to allocated memory on success, NULL on failure.

struct **device_connection**
Device Connection Descriptor

Definition

```
struct device_connection {
  struct fwnode_handle    *fwnode;
  const char              *endpoint[2];
  const char              *id;
  struct list_head        list;
};
```

Members

fwnode The device node of the connected device

endpoint The names of the two devices connected together

id Unique identifier for the connection

list List head, private, for internal use only

NOTE

fwnode is not used together with **endpoint**. **fwnode** is used when platform firmware defines the connection. When the connection is registered with `device_connection_add()` **endpoint** is used instead.

void **device_connections_add**(struct device_connection * cons)
Add multiple device connections at once

Parameters

struct device_connection * cons Zero terminated array of device connection descriptors

void **device_connections_remove**(struct device_connection * cons)
Remove multiple device connections at once

Parameters

struct device_connection * cons Zero terminated array of device connection descriptors

enum **device_link_state**
Device link states.

Constants

DL_STATE_NONE The presence of the drivers is not being tracked.

DL_STATE_DORMANT None of the supplier/consumer drivers is present.

DL_STATE_AVAILABLE The supplier driver is present, but the consumer is not.

DL_STATE_CONSUMER_PROBE The consumer is probing (supplier driver present).

DL_STATE_ACTIVE Both the supplier and consumer drivers are present.

DL_STATE_SUPPLIER_UNBIND The supplier driver is unbinding.

struct **device_link**
Device link representation.

Definition

```
struct device_link {
  struct device *supplier;
  struct list_head s_node;
  struct device *consumer;
  struct list_head c_node;
  enum device_link_state status;
  u32 flags;
  refcount_t rpm_active;
  struct kref kref;
#ifdef CONFIG_SRCU;
  struct rcu_head rcu_head;
#endif;
  bool supplier_preactivated;
};
```

Members

supplier The device on the supplier end of the link.

s_node Hook to the supplier device's list of links to consumers.

consumer The device on the consumer end of the link.

c_node Hook to the consumer device's list of links to suppliers.

status The state of the link (with respect to the presence of drivers).

flags Link flags.

rpm_active Whether or not the consumer device is runtime-PM-active.

kref Count repeated addition of the same link.

rcu_head An RCU head to use for deferred execution of SRCU callbacks.

supplier_preactivated Supplier has been made active before consumer probe.

enum **dl_dev_state**
Device driver presence tracking information.

Constants

DL_DEV_NO_DRIVER There is no driver attached to the device.

DL_DEV_PROBING A driver is probing.

DL_DEV_DRIVER_BOUND The driver has been bound to the device.

DL_DEV_UNBINDING The driver is unbinding from the device.

struct **dev_links_info**
Device data related to device links.

Definition

```
struct dev_links_info {
  struct list_head suppliers;
```

(continues on next page)

(continued from previous page)

```
  struct list_head consumers;
  struct list_head needs_suppliers;
  struct list_head defer_sync;
  bool need_for_probe;
  enum dl_dev_state status;
};
```

Members

suppliers List of links to supplier devices.

consumers List of links to consumer devices.

needs_suppliers Hook to global list of devices waiting for suppliers.

defer_sync Hook to global list of devices that have deferred sync_state.

need_for_probe If needs_suppliers is on a list, this indicates if the suppliers are needed for probe or not.

status Driver status information.

struct **device**
The basic device structure

Definition

```
struct device {
  struct kobject kobj;
  struct device           *parent;
  struct device_private   *p;
  const char              *init_name;
  const struct device_type *type;
  struct bus_type *bus;
  struct device_driver *driver;
  void *platform_data;
  void *driver_data;
#ifdef CONFIG_PROVE_LOCKING;
  struct mutex            lockdep_mutex;
#endif;
  struct mutex            mutex;
  struct dev_links_info   links;
  struct dev_pm_info      power;
  struct dev_pm_domain    *pm_domain;
#ifdef CONFIG_GENERIC_MSI_IRQ_DOMAIN;
  struct irq_domain       *msi_domain;
#endif;
#ifdef CONFIG_PINCTRL;
  struct dev_pin_info     *pins;
#endif;
#ifdef CONFIG_GENERIC_MSI_IRQ;
  struct list_head        msi_list;
#endif;
  const struct dma_map_ops *dma_ops;
  u64 *dma_mask;
  u64 coherent_dma_mask;
  u64 bus_dma_limit;
  unsigned long   dma_pfn_offset;
```

(continues on next page)

(continued from previous page)

```
  struct device_dma_parameters *dma_parms;
  struct list_head        dma_pools;
#ifdef CONFIG_DMA_DECLARE_COHERENT;
  struct dma_coherent_mem *dma_mem;
#endif;
#ifdef CONFIG_DMA_CMA;
  struct cma *cma_area;
#endif;
  struct dev_archdata     archdata;
  struct device_node      *of_node;
  struct fwnode_handle    *fwnode;
#ifdef CONFIG_NUMA;
  int numa_node;
#endif;
  dev_t devt;
  u32 id;
  spinlock_t devres_lock;
  struct list_head        devres_head;
  struct class            *class;
  const struct attribute_group **groups;
  void (*release)(struct device *dev);
  struct iommu_group      *iommu_group;
  struct dev_iommu        *iommu;
  bool offline_disabled:1;
  bool offline:1;
  bool of_node_reused:1;
  bool state_synced:1;
#if defined(CONFIG_ARCH_HAS_SYNC_DMA_FOR_DEVICE) ||     defined(CONFIG_
↪ARCH_HAS_SYNC_DMA_FOR_CPU) ||     defined(CONFIG_ARCH_HAS_SYNC_DMA_FOR_
↪CPU_ALL);
  bool dma_coherent:1;
#endif;
};
```

Members

kobj A top-level, abstract class from which other classes are derived.

parent The device's "parent" device, the device to which it is attached. In most cases, a parent device is some sort of bus or host controller. If parent is NULL, the device, is a top-level device, which is not usually what you want.

p Holds the private data of the driver core portions of the device. See the comment of the struct device_private for detail.

init_name Initial name of the device.

type The type of device. This identifies the device type and carries type-specific information.

bus Type of bus device is on.

driver Which driver has allocated this

platform_data Platform data specific to the device.

driver_data Private pointer for driver specific info.

lockdep_mutex An optional debug lock that a subsystem can use as a peer lock to gain localized lockdep coverage of the device_lock.

mutex Mutex to synchronize calls to its driver.

links Links to suppliers and consumers of this device.

power For device power management. See Documentation/driver-api/pm/devices.rst for details.

pm_domain Provide callbacks that are executed during system suspend, hibernation, system resume and during runtime PM transitions along with subsystem-level and driver-level callbacks.

msi_domain The generic MSI domain this device is using.

pins For device pin management. See Documentation/driver-api/pinctl.rst for details.

msi_list Hosts MSI descriptors

dma_ops DMA mapping operations for this device.

dma_mask Dma mask (if dma’ble device).

coherent_dma_mask Like dma_mask, but for alloc_coherent mapping as not all hardware supports 64-bit addresses for consistent allocations such descriptors.

bus_dma_limit Limit of an upstream bridge or bus which imposes a smaller DMA limit than the device itself supports.

dma_pfn_offset offset of DMA memory range relatively of RAM

dma_parms A low level driver may set these to teach IOMMU code about segment limitations.

dma_pools Dma pools (if dma’ble device).

dma_mem Internal for coherent mem override.

cma_area Contiguous memory area for dma allocations

archdata For arch-specific additions.

of_node Associated device tree node.

fwnode Associated device node supplied by platform firmware.

numa_node NUMA node this device is close to.

devt For creating the sysfs “dev”.

id device instance

devres_lock Spinlock to protect the resource of the device.

devres_head The resources list of the device.

class The class of the device.

groups Optional attribute groups.

release Callback to free the device after all references have gone away. This should be set by the allocator of the device (i.e. the bus driver that discovered the device).

iommu_group IOMMU group the device belongs to.

iommu Per device generic IOMMU runtime data

offline_disabled If set, the device is permanently online.

offline Set after successful invocation of bus type's .offline().

of_node_reused Set if the device-tree node is shared with an ancestor device.

state_synced The hardware state of this device has been synced to match the software state of this device by calling the driver/bus sync_state() callback.

dma_coherent this particular device is dma coherent, even if the architecture supports non-coherent devices.

Example

For devices on custom boards, as typical of embedded and SOC based hardware, Linux often uses platform_data to point to board-specific structures describing devices and how they are wired. That can include what ports are available, chip variants, which GPIO pins act in what additional roles, and so on. This shrinks the "Board Support Packages" (BSPs) and minimizes board-specific #ifdefs in drivers.

Description

At the lowest level, every device in a Linux system is represented by an instance of struct device. The device structure contains the information that the device model core needs to model the system. Most subsystems, however, track additional information about the devices they host. As a result, it is rare for devices to be represented by bare device structures; instead, that structure, like kobject structures, is usually embedded within a higher-level representation of the device.

bool **device_iommu_mapped**(struct device * dev)
Returns true when the device DMA is translated by an IOMMU

Parameters

struct device * dev Device to perform the check on

3.2 Device Drivers Base

void **driver_init**(void)
initialize driver model.

Parameters

void no arguments

Description

Call the driver model init functions to initialize their subsystems. Called early from init/main.c.

int **driver_for_each_device**(struct device_driver * drv, struct device * start, void * data, int (*fn)(struct device *, void *))
Iterator for devices bound to a driver.

Parameters

struct device_driver * drv Driver we're iterating.

struct device * start Device to begin with

void * data Data to pass to the callback.

int (*)(struct device *, void *) fn Function to call for each device.

Description

Iterate over the **drv**'s list of devices calling **fn** for each one.

struct device * **driver_find_device**(struct device_driver * drv, struct device * start, const void * data, int (*match)(struct device *dev, const void *data))
device iterator for locating a particular device.

Parameters

struct device_driver * drv The device's driver

struct device * start Device to begin with

const void * data Data to pass to match function

int (*)(struct device *dev, const void *data) match Callback function to check device

Description

This is similar to the `driver_for_each_device()` function above, but it returns a reference to a device that is 'found' for later use, as determined by the **match** callback.

The callback should return 0 if the device doesn't match and non-zero if it does. If the callback returns non-zero, this function will return to the caller and not iterate over any more devices.

int **driver_create_file**(struct device_driver * drv, const struct driver_attribute * attr)
create sysfs file for driver.

Parameters

struct device_driver * drv driver.

const struct driver_attribute * attr driver attribute descriptor.

void **driver_remove_file**(struct device_driver * drv, const struct driver_attribute * attr)
remove sysfs file for driver.

Parameters

struct device_driver * drv driver.

const struct driver_attribute * attr driver attribute descriptor.

int **driver_register**(struct device_driver * drv)
register driver with bus

Parameters

struct device_driver * drv driver to register

Description

We pass off most of the work to the bus_add_driver() call, since most of the things we have to do deal with the bus structures.

void **driver_unregister**(struct device_driver * drv)
remove driver from system.

Parameters

struct device_driver * drv driver.

Description

Again, we pass off most of the work to the bus-level call.

struct device_driver * **driver_find**(const char * name, struct bus_type * bus)
locate driver on a bus by its name.

Parameters

const char * name name of the driver.

struct bus_type * bus bus to scan for the driver.

Description

Call `kset_find_obj()` to iterate over list of drivers on a bus to find driver by name. Return driver if found.

This routine provides no locking to prevent the driver it returns from being unregistered or unloaded while the caller is using it. The caller is responsible for preventing this.

struct device_link * **device_link_add**(struct device * consumer, struct device * supplier, u32 flags)
Create a link between two devices.

Parameters

struct device * consumer Consumer end of the link.

struct device * supplier Supplier end of the link.

u32 flags Link flags.

Description

The caller is responsible for the proper synchronization of the link creation with runtime PM. First, setting the DL_FLAG_PM_RUNTIME flag will cause the runtime PM framework to take the link into account. Second, if the DL_FLAG_RPM_ACTIVE flag is set in addition to it, the supplier devices will be forced into the active metastate and reference-counted upon the creation of the

link. If DL_FLAG_PM_RUNTIME is not set, DL_FLAG_RPM_ACTIVE will be ignored.

If DL_FLAG_STATELESS is set in **flags**, the caller of this function is expected to release the link returned by it directly with the help of either `device_link_del()` or `device_link_remove()`.

If that flag is not set, however, the caller of this function is handing the management of the link over to the driver core entirely and its return value can only be used to check whether or not the link is present. In that case, the DL_FLAG_AUTOREMOVE_CONSUMER and DL_FLAG_AUTOREMOVE_SUPPLIER device link flags can be used to indicate to the driver core when the link can be safely deleted. Namely, setting one of them in **flags** indicates to the driver core that the link is not going to be used (by the given caller of this function) after unbinding the consumer or supplier driver, respectively, from its device, so the link can be deleted at that point. If none of them is set, the link will be maintained until one of the devices pointed to by it (either the consumer or the supplier) is unregistered.

Also, if DL_FLAG_STATELESS, DL_FLAG_AUTOREMOVE_CONSUMER and DL_FLAG_AUTOREMOVE_SUPPLIER are not set in **flags** (that is, a persistent managed device link is being added), the DL_FLAG_AUTOPROBE_CONSUMER flag can be used to request the driver core to automaticall probe for a consmer driver after successfully binding a driver to the supplier device.

The combination of DL_FLAG_STATELESS and one of DL_FLAG_AUTOREMOVE_CONSUMER, DL_FLAG_AUTOREMOVE_SUPPLIER, or DL_FLAG_AUTOPROBE_CONSUMER set in **flags** at the same time is invalid and will cause NULL to be returned upfront. However, if a device link between the given **consumer** and **supplier** pair exists already when this function is called for them, the existing link will be returned regardless of its current type and status (the link' s flags may be modified then). The caller of this function is then expected to treat the link as though it has just been created, so (in particular) if DL_FLAG_STATELESS was passed in **flags**, the link needs to be released explicitly when not needed any more (as stated above).

A side effect of the link creation is re-ordering of dpm_list and the devices_kset list by moving the consumer device and all devices depending on it to the ends of these lists (that does not happen to devices that have not been registered when this function is called).

The supplier device is required to be registered when this function is called and NULL will be returned if that is not the case. The consumer device need not be registered, however.

void **device_link_del**(struct device_link * link)
Delete a stateless link between two devices.

Parameters

struct device_link * link Device link to delete.

Description

The caller must ensure proper synchronization of this function with runtime PM. If the link was added multiple times, it needs to be deleted as often. Care is

required for hotplugged devices: Their links are purged on removal and calling `device_link_del()` is then no longer allowed.

void **device_link_remove**(void * consumer, struct device * supplier)
Delete a stateless link between two devices.

Parameters

void * consumer Consumer end of the link.

struct device * supplier Supplier end of the link.

Description

The caller must ensure proper synchronization of this function with runtime PM.

const char * **dev_driver_string**(const struct device * dev)
Return a device's driver name, if at all possible

Parameters

const struct device * dev struct device to get the name of

Description

Will return the device's driver's name if it is bound to a device. If the device is not bound to a driver, it will return the name of the bus it is attached to. If it is not attached to a bus either, an empty string will be returned.

int **devm_device_add_group**(struct device * dev, const struct attribute_group * grp)
given a device, create a managed attribute group

Parameters

struct device * dev The device to create the group for

const struct attribute_group * grp The attribute group to create

Description

This function creates a group for the first time. It will explicitly warn and error if any of the attribute files being created already exist.

Returns 0 on success or error code on failure.

void **devm_device_remove_group**(struct device * dev, const struct attribute_group * grp)

Parameters

struct device * dev device to remove the group from

const struct attribute_group * grp group to remove

Description

This function removes a group of attributes from a device. The attributes previously have to have been created for this group, otherwise it will fail.

int **devm_device_add_groups**(struct device * dev, const struct attribute_group ** groups)
create a bunch of managed attribute groups

Parameters

struct device * dev The device to create the group for

const struct attribute_group ** groups The attribute groups to create, NULL terminated

Description

This function creates a bunch of managed attribute groups. If an error occurs when creating a group, all previously created groups will be removed, unwinding everything back to the original state when this function was called. It will explicitly warn and error if any of the attribute files being created already exist.

Returns 0 on success or error code from sysfs_create_group on failure.

void **devm_device_remove_groups**(struct device * dev, const struct attribute_group ** groups)
remove a list of managed groups

Parameters

struct device * dev The device for the groups to be removed from

const struct attribute_group ** groups NULL terminated list of groups to be removed

Description

If groups is not NULL, remove the specified groups from the device.

int **device_create_file**(struct device * dev, const struct device_attribute * attr)
create sysfs attribute file for device.

Parameters

struct device * dev device.

const struct device_attribute * attr device attribute descriptor.

void **device_remove_file**(struct device * dev, const struct device_attribute * attr)
remove sysfs attribute file.

Parameters

struct device * dev device.

const struct device_attribute * attr device attribute descriptor.

bool **device_remove_file_self**(struct device * dev, const struct device_attribute * attr)
remove sysfs attribute file from its own method.

Parameters

struct device * dev device.

const struct device_attribute * attr device attribute descriptor.

Description

See kernfs_remove_self() for details.

int **device_create_bin_file**(struct device * dev, const struct bin_attribute * attr)
create sysfs binary attribute file for device.

Parameters

struct device * dev device.

const struct bin_attribute * attr device binary attribute descriptor.

void **device_remove_bin_file**(struct device * dev, const struct bin_attribute * attr)
remove sysfs binary attribute file

Parameters

struct device * dev device.

const struct bin_attribute * attr device binary attribute descriptor.

void **device_initialize**(struct device * dev)
init device structure.

Parameters

struct device * dev device.

Description

This prepares the device for use by other layers by initializing its fields. It is the first half of `device_register()`, if called by that function, though it can also be called separately, so one may use **dev**' s fields. In particular, `get_device()`/`put_device()` may be used for reference counting of **dev** after calling this function.

All fields in **dev** must be initialized by the caller to 0, except for those explicitly set to some other value. The simplest approach is to use kzalloc() to allocate the structure containing **dev**.

NOTE

Use `put_device()` to give up your reference instead of freeing **dev** directly once you have called this function.

int **dev_set_name**(struct device * dev, const char * fmt, ...)
set a device name

Parameters

struct device * dev device

const char * fmt format string for the device' s name

... variable arguments

int **device_add**(struct device * dev)
add device to device hierarchy.

Parameters

struct device * dev device.

Description

This is part 2 of `device_register()`, though may be called separately _iff_ `device_initialize()` has been called separately.

This adds **dev** to the kobject hierarchy via `kobject_add()`, adds it to the global and sibling lists for the device, then adds it to the other relevant subsystems of the driver model.

Do not call this routine or `device_register()` more than once for any device structure. The driver model core is not designed to work with devices that get unregistered and then spring back to life. (Among other things, it's very hard to guarantee that all references to the previous incarnation of **dev** have been dropped.) Allocate and register a fresh new struct device instead.

Rule of thumb is: if `device_add()` succeeds, you should call `device_del()` when you want to get rid of it. If `device_add()` has not succeeded, use only `put_device()` to drop the reference count.

NOTE

Never directly free **dev** after calling this function, even if it returned an error! Always use `put_device()` to give up your reference instead.

int **device_register**(struct device * dev)
register a device with the system.

Parameters

struct device * dev pointer to the device structure

Description

This happens in two clean steps - initialize the device and add it to the system. The two steps can be called separately, but this is the easiest and most common. I.e. you should only call the two helpers separately if have a clearly defined need to use and refcount the device before it is added to the hierarchy.

For more information, see the kerneldoc for `device_initialize()` and `device_add()`.

NOTE

Never directly free **dev** after calling this function, even if it returned an error! Always use `put_device()` to give up the reference initialized in this function instead.

struct device * **get_device**(struct device * dev)
increment reference count for device.

Parameters

struct device * dev device.

Description

This simply forwards the call to `kobject_get()`, though we do take care to provide for the case that we get a NULL pointer passed in.

void **put_device**(struct device * dev)
decrement reference count.

Parameters

struct device * dev device in question.

void **device_del**(struct device * dev)
delete device from system.

Parameters

struct device * dev device.

Description

This is the first part of the device unregistration sequence. This removes the device from the lists we control from here, has it removed from the other driver model subsystems it was added to in `device_add()`, and removes it from the kobject hierarchy.

NOTE

this should be called manually _iff_ `device_add()` was also called manually.

void **device_unregister**(struct device * dev)
unregister device from system.

Parameters

struct device * dev device going away.

Description

We do this in two parts, like we do `device_register()`. First, we remove it from all the subsystems with `device_del()`, then we decrement the reference count via `put_device()`. If that is the final reference count, the device will be cleaned up via device_release() above. Otherwise, the structure will stick around until the final reference to the device is dropped.

int **device_for_each_child**(struct device * parent, void * data, int (*fn)(struct device *dev, void *data))
device child iterator.

Parameters

struct device * parent parent struct device.

void * data data for the callback.

int (*)(struct device *dev, void *data) fn function to be called for each device.

Description

Iterate over **parent**’ s child devices, and call **fn** for each, passing it **data**.

We check the return of **fn** each time. If it returns anything other than 0, we break out and return that value.

int **device_for_each_child_reverse**(struct device * parent, void * data, int (*fn)(struct device *dev, void *data))
device child iterator in reversed order.

Parameters

struct device * parent parent struct device.

void * data data for the callback.

int (*)(struct device *dev, void *data) fn function to be called for each device.

Description

Iterate over **parent**'s child devices, and call **fn** for each, passing it **data**.

We check the return of **fn** each time. If it returns anything other than 0, we break out and return that value.

struct device * **device_find_child**(struct device * parent, void * data, int (*match)(struct device *dev, void *data))
device iterator for locating a particular device.

Parameters

struct device * parent parent struct device

void * data Data to pass to match function

int (*)(struct device *dev, void *data) match Callback function to check device

Description

This is similar to the `device_for_each_child()` function above, but it returns a reference to a device that is 'found' for later use, as determined by the **match** callback.

The callback should return 0 if the device doesn't match and non-zero if it does. If the callback returns non-zero and a reference to the current device can be obtained, this function will return to the caller and not iterate over any more devices.

NOTE

you will need to drop the reference with `put_device()` after use.

struct device * **device_find_child_by_name**(struct device * parent, const char * name)
device iterator for locating a child device.

Parameters

struct device * parent parent struct device

const char * name name of the child device

Description

This is similar to the `device_find_child()` function above, but it returns a reference to a device that has the name **name**.

NOTE

you will need to drop the reference with `put_device()` after use.

struct device * **__root_device_register**(const char * name, struct module * owner)
allocate and register a root device

Parameters

const char * name root device name

struct module * owner owner module of the root device, usually THIS_MODULE

Description

This function allocates a root device and registers it using `device_register()`. In order to free the returned device, use `root_device_unregister()`.

Root devices are dummy devices which allow other devices to be grouped under /sys/devices. Use this function to allocate a root device and then use it as the parent of any device which should appear under /sys/devices/{name}

The /sys/devices/{name} directory will also contain a 'module' symlink which points to the **owner** directory in sysfs.

Returns `struct device` pointer on success, or ERR_PTR() on error.

Note

You probably want to use root_device_register().

void **root_device_unregister**(struct device * dev)
unregister and free a root device

Parameters

struct device * dev device going away

Description

This function unregisters and cleans up a device that was created by root_device_register().

struct device * **device_create**(struct class * class, struct device * parent, dev_t devt, void * drvdata, const char * fmt, ...)
creates a device and registers it with sysfs

Parameters

struct class * class pointer to the struct class that this device should be registered to

struct device * parent pointer to the parent struct device of this new device, if any

dev_t devt the dev_t for the char device to be added

void * drvdata the data to be added to the device for callbacks

const char * fmt string for the device's name

... variable arguments

Description

This function can be used by char device classes. A struct device will be created in sysfs, registered to the specified class.

A "dev" file will be created, showing the dev_t for the device, if the dev_t is not 0,0. If a pointer to a parent struct device is passed in, the newly created struct

device will be a child of that device in sysfs. The pointer to the struct device will be returned from the call. Any further sysfs files that might be required can be created using this pointer.

Returns `struct device` pointer on success, or ERR_PTR() on error.

Note

the struct class passed to this function must have previously been created with a call to class_create().

struct device * **device_create_with_groups**(struct class * class, struct device * parent, dev_t devt, void * drvdata, const struct attribute_group ** groups, const char * fmt, ...)
creates a device and registers it with sysfs

Parameters

struct class * class pointer to the struct class that this device should be registered to

struct device * parent pointer to the parent struct device of this new device, if any

dev_t devt the dev_t for the char device to be added

void * drvdata the data to be added to the device for callbacks

const struct attribute_group ** groups NULL-terminated list of attribute groups to be created

const char * fmt string for the device's name

... variable arguments

Description

This function can be used by char device classes. A struct device will be created in sysfs, registered to the specified class. Additional attributes specified in the groups parameter will also be created automatically.

A "dev" file will be created, showing the dev_t for the device, if the dev_t is not 0,0. If a pointer to a parent struct device is passed in, the newly created struct device will be a child of that device in sysfs. The pointer to the struct device will be returned from the call. Any further sysfs files that might be required can be created using this pointer.

Returns `struct device` pointer on success, or ERR_PTR() on error.

Note

the struct class passed to this function must have previously been created with a call to class_create().

void **device_destroy**(struct class * class, dev_t devt)
removes a device that was created with `device_create()`

Parameters

struct class * class pointer to the struct class that this device was registered with

dev_t devt the dev_t of the device that was previously registered

Description

This call unregisters and cleans up a device that was created with a call to `device_create()`.

int **device_rename**(struct device * dev, const char * new_name)
renames a device

Parameters

struct device * dev the pointer to the struct device to be renamed

const char * new_name the new name of the device

Description

It is the responsibility of the caller to provide mutual exclusion between two different calls of device_rename on the same device to ensure that new_name is valid and won't conflict with other devices.

Renaming devices is racy at many levels, symlinks and other stuff are not replaced atomically, and you get a "move" uevent, but it's not easy to connect the event to the old and new device. Device nodes are not renamed at all, there isn't even support for that in the kernel now.

In the meantime, during renaming, your target name might be taken by another driver, creating conflicts. Or the old name is taken directly after you renamed it – then you get events for the same DEVPATH, before you even see the "move" event. It's just a mess, and nothing new should ever rely on kernel device renaming. Besides that, it's not even implemented now for other things than (driver-core wise very simple) network devices.

We are currently about to change network renaming in udev to completely disallow renaming of devices in the same namespace as the kernel uses, because we can't solve the problems properly, that arise with swapping names of multiple interfaces without races. Means, renaming of eth[0-9]* will only be allowed to some other name than eth[0-9]*, for the aforementioned reasons.

Make up a "real" name in the driver before you register anything, or add some other attributes for userspace to find the device, or use udev to add symlinks – but never rename kernel devices later, it's a complete mess. We don't even want to get into that and try to implement the missing pieces in the core. We really have other pieces to fix in the driver core mess. :)

Note

Don't call this function. Currently, the networking layer calls this function, but that will change. The following text from Kay Sievers offers some insight:

int **device_move**(struct device * dev, struct device * new_parent, enum dpm_order dpm_order)
moves a device to a new parent

Parameters

struct device * dev the pointer to the struct device to be moved

struct device * new_parent the new parent of the device (can be NULL)

enum dpm_order dpm_order how to reorder the dpm_list

int **device_change_owner**(struct device * dev, kuid_t kuid, kgid_t kgid)
change the owner of an existing device.

Parameters

struct device * dev device.

kuid_t kuid new owner's kuid

kgid_t kgid new owner's kgid

Description

This changes the owner of **dev** and its corresponding sysfs entries to **kuid/kgid**. This function closely mirrors how **dev** was added via driver core.

Returns 0 on success or error code on failure.

void **set_primary_fwnode**(struct device * dev, struct fwnode_handle * fwnode)
Change the primary firmware node of a given device.

Parameters

struct device * dev Device to handle.

struct fwnode_handle * fwnode New primary firmware node of the device.

Description

Set the device's firmware node pointer to **fwnode**, but if a secondary firmware node of the device is present, preserve it.

void **set_secondary_fwnode**(struct device * dev, struct fwnode_handle * fwnode)
Change the secondary firmware node of a given device.

Parameters

struct device * dev Device to handle.

struct fwnode_handle * fwnode New secondary firmware node of the device.

Description

If a primary firmware node of the device is present, set its secondary pointer to **fwnode**. Otherwise, set the device's firmware node pointer to **fwnode**.

void **device_set_of_node_from_dev**(struct device * dev, const struct device * dev2)
reuse device-tree node of another device

Parameters

struct device * dev device whose device-tree node is being set

const struct device * dev2 device whose device-tree node is being reused

Description

Takes another reference to the new device-tree node after first dropping any reference held to the old node.

void **register_syscore_ops**(struct syscore_ops * ops)
Register a set of system core operations.

Parameters

struct syscore_ops * ops System core operations to register.

void **unregister_syscore_ops**(struct syscore_ops * ops)
Unregister a set of system core operations.

Parameters

struct syscore_ops * ops System core operations to unregister.

int **syscore_suspend**(void)
Execute all the registered system core suspend callbacks.

Parameters

void no arguments

Description

This function is executed with one CPU on-line and disabled interrupts.

void **syscore_resume**(void)
Execute all the registered system core resume callbacks.

Parameters

void no arguments

Description

This function is executed with one CPU on-line and disabled interrupts.

struct class * **__class_create**(struct module * owner, const char * name,
struct lock_class_key * key)
create a struct class structure

Parameters

struct module * owner pointer to the module that is to “own” this struct class

const char * name pointer to a string for the name of this class.

struct lock_class_key * key the lock_class_key for this class; used by mutex lock debugging

Description

This is used to create a struct class pointer that can then be used in calls to `device_create()`.

Returns `struct class` pointer on success, or ERR_PTR() on error.

Note, the pointer created here is to be destroyed when finished by making a call to `class_destroy()`.

void **class_destroy**(struct class * cls)
destroys a struct class structure

Parameters

struct class * cls pointer to the struct class that is to be destroyed

Description

Note, the pointer to be destroyed must have been created with a call to class_create().

void **class_dev_iter_init**(struct class_dev_iter * iter, struct class * class, struct device * start, const struct device_type * type)
initialize class device iterator

Parameters

struct class_dev_iter * iter class iterator to initialize

struct class * class the class we wanna iterate over

struct device * start the device to start iterating from, if any

const struct device_type * type device_type of the devices to iterate over, NULL for all

Description

Initialize class iterator **iter** such that it iterates over devices of **class**. If **start** is set, the list iteration will start there, otherwise if it is NULL, the iteration starts at the beginning of the list.

struct device * **class_dev_iter_next**(struct class_dev_iter * iter)
iterate to the next device

Parameters

struct class_dev_iter * iter class iterator to proceed

Description

Proceed **iter** to the next device and return it. Returns NULL if iteration is complete.

The returned device is referenced and won't be released till iterator is proceed to the next device or exited. The caller is free to do whatever it wants to do with the device including calling back into class code.

void **class_dev_iter_exit**(struct class_dev_iter * iter)
finish iteration

Parameters

struct class_dev_iter * iter class iterator to finish

Description

Finish an iteration. Always call this function after iteration is complete whether the iteration ran till the end or not.

int **class_for_each_device**(struct class * class, struct device * start, void * data, int (*fn)(struct device *, void *))
device iterator

Parameters

struct class * class the class we're iterating

struct device * start the device to start with in the list, if any.

void * data data for the callback

int (*)(struct device *, void *) fn function to be called for each device

Description

Iterate over **class**'s list of devices, and call **fn** for each, passing it **data**. If **start** is set, the list iteration will start there, otherwise if it is NULL, the iteration starts at the beginning of the list.

We check the return of **fn** each time. If it returns anything other than 0, we break out and return that value.

fn is allowed to do anything including calling back into class code. There's no locking restriction.

struct device * **class_find_device**(struct class * class, struct device * start, const void * data, int (*match)(struct device *, const void *))
device iterator for locating a particular device

Parameters

struct class * class the class we're iterating

struct device * start Device to begin with

const void * data data for the match function

int (*)(struct device *, const void *) match function to check device

Description

This is similar to the class_for_each_dev() function above, but it returns a reference to a device that is 'found' for later use, as determined by the **match** callback.

The callback should return 0 if the device doesn't match and non-zero if it does. If the callback returns non-zero, this function will return to the caller and not iterate over any more devices.

Note, you will need to drop the reference with `put_device()` after use.

match is allowed to do anything including calling back into class code. There's no locking restriction.

struct class_compat * **class_compat_register**(const char * name)
register a compatibility class

Parameters

const char * name the name of the class

Description

Compatibility class are meant as a temporary user-space compatibility workaround when converting a family of class devices to a bus devices.

void **class_compat_unregister**(struct class_compat * cls)
unregister a compatibility class

Parameters

struct class_compat * cls the class to unregister

int **class_compat_create_link**(struct class_compat * cls, struct device * dev, struct device * device_link)
create a compatibility class device link to a bus device

Parameters

struct class_compat * cls the compatibility class

struct device * dev the target bus device

struct device * device_link an optional device to which a "device" link should be created

void **class_compat_remove_link**(struct class_compat * cls, struct device * dev, struct device * device_link)
remove a compatibility class device link to a bus device

Parameters

struct class_compat * cls the compatibility class

struct device * dev the target bus device

struct device * device_link an optional device to which a "device" link was previously created

struct **node_access_nodes**
Access class device to hold user visible relationships to other nodes.

Definition

```
struct node_access_nodes {
  struct device           dev;
  struct list_head        list_node;
  unsigned access;
#ifdef CONFIG_HMEM_REPORTING;
  struct node_hmem_attrs  hmem_attrs;
#endif;
};
```

Members

dev Device for this memory access class

list_node List element in the node's access list

access The access class rank

hmem_attrs Heterogeneous memory performance attributes

void **node_set_perf_attrs**(unsigned int nid, struct node_hmem_attrs * hmem_attrs, unsigned access)
Set the performance values for given access class

Parameters

unsigned int nid Node identifier to be set

struct node_hmem_attrs * hmem_attrs Heterogeneous memory performance attributes

unsigned access The access class the for the given attributes

struct **node_cache_info**
Internal tracking for memory node caches

Definition

```
struct node_cache_info {
  struct device dev;
  struct list_head node;
  struct node_cache_attrs cache_attrs;
};
```

Members

dev Device represeting the cache level

node List element for tracking in the node

cache_attrs Attributes for this cache level

void **node_add_cache**(unsigned int nid, struct node_cache_attrs * cache_attrs)
add cache attribute to a memory node

Parameters

unsigned int nid Node identifier that has new cache attributes

struct node_cache_attrs * cache_attrs Attributes for the cache being added

void **unregister_node**(struct node * node)
unregister a node device

Parameters

struct node * node node going away

Description

Unregisters a node device **node**. All the devices on the node must be unregistered before calling this function.

int **register_memory_node_under_compute_node**(unsigned int mem_nid, unsigned int cpu_nid, unsigned access)
link memory node to its compute node for a given access class.

Parameters

unsigned int mem_nid Memory node number

unsigned int cpu_nid Cpu node number

unsigned access Access class to register

Description

For use with platforms that may have separate memory and compute nodes. This function will export node relationships linking which memory initiator nodes can access memory targets at a given ranked access class.

int **request_firmware**(const struct firmware ** firmware_p, const char * name, struct device * device)
send firmware request and wait for it

Parameters

const struct firmware ** firmware_p pointer to firmware image

const char * name name of firmware file

struct device * device device for which firmware is being loaded

firmware_p will be used to return a firmware image by the name of **name** for device **device**.

Should be called from user context where sleeping is allowed.

name will be used as $FIRMWARE in the uevent environment and should be distinctive enough not to be confused with any other firmware image for this or any other device.

Caller must hold the reference count of **device**.

The function can be called safely inside device's suspend and resume callback.

int **firmware_request_nowarn**(const struct firmware ** firmware, const char * name, struct device * device)
request for an optional fw module

Parameters

const struct firmware ** firmware pointer to firmware image

const char * name name of firmware file

struct device * device device for which firmware is being loaded

Description

This function is similar in behaviour to `request_firmware()`, except it doesn't produce warning messages when the file is not found. The sysfs fallback mechanism is enabled if direct filesystem lookup fails, however, however failures to find the firmware file with it are still suppressed. It is therefore up to the driver to check for the return value of this call and to decide when to inform the users of errors.

int **request_firmware_direct**(const struct firmware ** firmware_p, const char * name, struct device * device)
load firmware directly without usermode helper

Parameters

const struct firmware ** firmware_p pointer to firmware image

const char * name name of firmware file

struct device * device device for which firmware is being loaded

Description

This function works pretty much like `request_firmware()`, but this doesn't fall back to usermode helper even if the firmware couldn't be loaded directly from fs. Hence it's useful for loading optional firmwares, which aren't always present, without extra long timeouts of udev.

int **firmware_request_platform**(const struct firmware ** firmware, const char * name, struct device * device)
request firmware with platform-fw fallback

Parameters

const struct firmware ** firmware pointer to firmware image

const char * name name of firmware file

struct device * device device for which firmware is being loaded

Description

This function is similar in behaviour to request_firmware, except that if direct filesystem lookup fails, it will fallback to looking for a copy of the requested firmware embedded in the platform's main (e.g. UEFI) firmware.

int **firmware_request_cache**(struct device * device, const char * name)
cache firmware for suspend so resume can use it

Parameters

struct device * device device for which firmware should be cached for

const char * name name of firmware file

Description

There are some devices with an optimization that enables the device to not require loading firmware on system reboot. This optimization may still require the firmware present on resume from suspend. This routine can be used to ensure the firmware is present on resume from suspend in these situations. This helper is not compatible with drivers which use `request_firmware_into_buf()` or `request_firmware_nowait()` with no uevent set.

int **request_firmware_into_buf**(const struct firmware ** firmware_p, const char * name, struct device * device, void * buf, size_t size)
load firmware into a previously allocated buffer

Parameters

const struct firmware ** firmware_p pointer to firmware image

const char * name name of firmware file

struct device * device device for which firmware is being loaded and DMA region allocated

void * buf address of buffer to load firmware into

size_t size size of buffer

Description

This function works pretty much like `request_firmware()`, but it doesn't allocate a buffer to hold the firmware data. Instead, the firmware is loaded directly into the buffer pointed to by **buf** and the **firmware_p** data member is pointed at **buf**.

This function doesn't cache firmware either.

void **release_firmware**(const struct firmware * fw)
release the resource associated with a firmware image

Parameters

const struct firmware * fw firmware resource to release

int **request_firmware_nowait**(struct module * module, bool uevent, const char * name, struct device * device, gfp_t gfp, void * context, void (*cont)(const struct firmware *fw, void *context))
asynchronous version of request_firmware

Parameters

struct module * module module requesting the firmware

bool uevent sends uevent to copy the firmware image if this flag is non-zero else the firmware copy must be done manually.

const char * name name of firmware file

struct device * device device for which firmware is being loaded

gfp_t gfp allocation flags

void * context will be passed over to **cont**, and **fw** may be `NULL` if firmware request fails.

void (*)(const struct firmware *fw, void *context) cont function will be called asynchronously when the firmware request is over.

Caller must hold the reference count of **device**.

Asynchronous variant of request_firmware() for user contexts:

- sleep for as small periods as possible since it may increase kernel boot time of built-in device drivers requesting firmware in their ->probe() methods, if **gfp** is GFP_KERNEL.
- can't sleep at all if **gfp** is GFP_ATOMIC.

int **transport_class_register**(struct transport_class * tclass)
register an initial transport class

Parameters

struct transport_class * tclass a pointer to the transport class structure to be initialised

Description

The transport class contains an embedded class which is used to identify it. The caller should initialise this structure with zeros and then generic class must have been initialised with the actual transport class unique name. There's a macro DECLARE_TRANSPORT_CLASS() to do this (declared classes still must be registered).

Returns 0 on success or error on failure.

void **transport_class_unregister**(struct transport_class * tclass)
unregister a previously registered class

Parameters

struct transport_class * tclass The transport class to unregister

Description

Must be called prior to deallocating the memory for the transport class.

int **anon_transport_class_register**(struct anon_transport_class * atc)
register an anonymous class

Parameters

struct anon_transport_class * atc The anon transport class to register

Description

The anonymous transport class contains both a transport class and a container. The idea of an anonymous class is that it never actually has any device attributes associated with it (and thus saves on container storage). So it can only be used for triggering events. Use prezero and then use DECLARE_ANON_TRANSPORT_CLASS() to initialise the anon transport class storage.

void **anon_transport_class_unregister**(struct anon_transport_class * atc)
unregister an anon class

Parameters

struct anon_transport_class * atc Pointer to the anon transport class to unregister

Description

Must be called prior to deallocating the memory for the anon transport class.

void **transport_setup_device**(struct device * dev)
declare a new dev for transport class association but don't make it visible yet.

Parameters

struct device * dev the generic device representing the entity being added

Description

Usually, dev represents some component in the HBA system (either the HBA itself or a device remote across the HBA bus). This routine is simply a trigger point to see if any set of transport classes wishes to associate with the added device. This

allocates storage for the class device and initialises it, but does not yet add it to the system or add attributes to it (you do this with transport_add_device). If you have no need for a separate setup and add operations, use transport_register_device (see transport_class.h).

int **transport_add_device**(struct device * dev)
declare a new dev for transport class association

Parameters

struct device * dev the generic device representing the entity being added

Description

Usually, dev represents some component in the HBA system (either the HBA itself or a device remote across the HBA bus). This routine is simply a trigger point used to add the device to the system and register attributes for it.

void **transport_configure_device**(struct device * dev)
configure an already set up device

Parameters

struct device * dev generic device representing device to be configured

Description

The idea of configure is simply to provide a point within the setup process to allow the transport class to extract information from a device after it has been setup. This is used in SCSI because we have to have a setup device to begin using the HBA, but after we send the initial inquiry, we use configure to extract the device parameters. The device need not have been added to be configured.

void **transport_remove_device**(struct device * dev)
remove the visibility of a device

Parameters

struct device * dev generic device to remove

Description

This call removes the visibility of the device (to the user from sysfs), but does not destroy it. To eliminate a device entirely you must also call transport_destroy_device. If you don't need to do remove and destroy as separate operations, use transport_unregister_device() (see transport_class.h) which will perform both calls for you.

void **transport_destroy_device**(struct device * dev)
destroy a removed device

Parameters

struct device * dev device to eliminate from the transport class.

Description

This call triggers the elimination of storage associated with the transport classdev. Note: all it really does is relinquish a reference to the classdev. The memory will not be freed until the last reference goes to zero. Note also that the classdev

retains a reference count on dev, so dev too will remain for as long as the transport class device remains around.

int **device_bind_driver**(struct device * dev)
bind a driver to one device.

Parameters

struct device * dev device.

Description

Allow manual attachment of a driver to a device. Caller must have already set **dev->driver**.

Note that this does not modify the bus reference count nor take the bus's rwsem. Please verify those are accounted for before calling this. (It is ok to call with no other effort from a driver's probe() method.)

This function must be called with the device lock held.

void **wait_for_device_probe**(void)

Parameters

void no arguments

Description

Wait for device probing to be completed.

int **device_attach**(struct device * dev)
try to attach device to a driver.

Parameters

struct device * dev device.

Description

Walk the list of drivers that the bus has and call driver_probe_device() for each pair. If a compatible pair is found, break out and return.

Returns 1 if the device was bound to a driver; 0 if no matching driver was found; -ENODEV if the device is not registered.

When called for a USB interface, **dev->parent** lock must be held.

int **driver_attach**(struct device_driver * drv)
try to bind driver to devices.

Parameters

struct device_driver * drv driver.

Description

Walk the list of devices that the bus has on it and try to match the driver with each one. If driver_probe_device() returns 0 and the **dev->driver** is set, we've found a compatible pair.

void **device_release_driver**(struct device * dev)
manually detach device from driver.

Parameters

struct device * dev device.

Description

Manually detach device from driver. When called for a USB interface, **dev->parent** lock must be held.

If this function is to be called with **dev->parent** lock held, ensure that the device's consumers are unbound in advance or that their locks can be acquired under the **dev->parent** lock.

struct platform_device * **platform_device_register_resndata**(struct device * parent, const char * name, int id, const struct resource * res, unsigned int num, const void * data, size_t size)

add a platform-level device with resources and platform-specific data

Parameters

struct device * parent parent device for the device we're adding

const char * name base name of the device we're adding

int id instance id

const struct resource * res set of resources that needs to be allocated for the device

unsigned int num number of resources

const void * data platform specific data for this platform device

size_t size size of platform specific data

Description

Returns `struct platform_device` pointer on success, or ERR_PTR() on error.

struct platform_device * **platform_device_register_simple**(const char * name, int id, const struct resource * res, unsigned int num)

add a platform-level device and its resources

Parameters

const char * name base name of the device we're adding

int id instance id

const struct resource * res set of resources that needs to be allocated for the device

unsigned int num number of resources

Description

This function creates a simple platform device that requires minimal resource and memory management. Canned release function freeing memory allocated for the device allows drivers using such devices to be unloaded without waiting for the last reference to the device to be dropped.

This interface is primarily intended for use with legacy drivers which probe hardware directly. Because such drivers create sysfs device nodes themselves, rather than letting system infrastructure handle such device enumeration tasks, they don't fully conform to the Linux driver model. In particular, when such drivers are built as modules, they can't be "hotplugged".

Returns `struct platform_device` pointer on success, or ERR_PTR() on error.

struct platform_device * **platform_device_register_data**(struct device * parent, const char * name, int id, const void * data, size_t size)

add a platform-level device with platform-specific data

Parameters

struct device * parent parent device for the device we're adding

const char * name base name of the device we're adding

int id instance id

const void * data platform specific data for this platform device

size_t size size of platform specific data

Description

This function creates a simple platform device that requires minimal resource and memory management. Canned release function freeing memory allocated for the device allows drivers using such devices to be unloaded without waiting for the last reference to the device to be dropped.

Returns `struct platform_device` pointer on success, or ERR_PTR() on error.

struct resource * **platform_get_resource**(struct platform_device * dev, unsigned int type, unsigned int num)

get a resource for a device

Parameters

struct platform_device * dev platform device

unsigned int type resource type

unsigned int num resource index

void __iomem * **devm_platform_get_and_ioremap_resource**(struct platform_device * pdev, unsigned int index, struct resource ** res)

call devm_ioremap_resource() for a platform device and get resource

Parameters

struct platform_device * pdev platform device to use both for memory resource lookup as well as resource management

unsigned int index resource index

struct resource ** res optional output parameter to store a pointer to the obtained resource.

void __iomem * **devm_platform_ioremap_resource**(struct platform_device * pdev, unsigned int index)

call devm_ioremap_resource() for a platform device

Parameters

struct platform_device * pdev platform device to use both for memory resource lookup as well as resource management

unsigned int index resource index

void __iomem * **devm_platform_ioremap_resource_byname**(struct platform_device * pdev, const char * name)

call devm_ioremap_resource for a platform device, retrieve the resource by name

Parameters

struct platform_device * pdev platform device to use both for memory resource lookup as well as resource management

const char * name name of the resource

int **platform_get_irq_optional**(struct platform_device * dev, unsigned int num)

get an optional IRQ for a device

Parameters

struct platform_device * dev platform device

unsigned int num IRQ number index

Description

Gets an IRQ for a platform device. Device drivers should check the return value for errors so as to not pass a negative integer value to the request_irq() APIs. This is the same as `platform_get_irq()`, except that it does not print an error message if an IRQ can not be obtained.

For example:

```
int irq = platform_get_irq_optional(pdev, 0);
if (irq < 0)
        return irq;
```

Return

non-zero IRQ number on success, negative error number on failure.

int **platform_get_irq**(struct platform_device * dev, unsigned int num)
get an IRQ for a device

Parameters

struct platform_device * dev platform device

unsigned int num IRQ number index

Description

Gets an IRQ for a platform device and prints an error message if finding the IRQ fails. Device drivers should check the return value for errors so as to not pass a negative integer value to the request_irq() APIs.

For example:

```
int irq = platform_get_irq(pdev, 0);
if (irq < 0)
        return irq;
```

Return

non-zero IRQ number on success, negative error number on failure.

int **platform_irq_count**(struct platform_device * dev)
Count the number of IRQs a platform device uses

Parameters

struct platform_device * dev platform device

Return

Number of IRQs a platform device uses or EPROBE_DEFER

struct resource * **platform_get_resource_byname**(struct platform_device * dev, unsigned int type, const char * name)
get a resource for a device by name

Parameters

struct platform_device * dev platform device

unsigned int type resource type

const char * name resource name

int **platform_get_irq_byname**(struct platform_device * dev, const char * name)
get an IRQ for a device by name

Parameters

struct platform_device * dev platform device

const char * name IRQ name

Description

Get an IRQ like `platform_get_irq()`, but then by name rather then by index.

Return

non-zero IRQ number on success, negative error number on failure.

int **platform_get_irq_byname_optional**(struct platform_device * dev, const char * name)
get an optional IRQ for a device by name

Parameters

struct platform_device * dev platform device

const char * name IRQ name

Description

Get an optional IRQ by name like `platform_get_irq_byname()`. Except that it does not print an error message if an IRQ can not be obtained.

Return

non-zero IRQ number on success, negative error number on failure.

int **platform_add_devices**(struct platform_device ** devs, int num)
add a numbers of platform devices

Parameters

struct platform_device ** devs array of platform devices to add

int num number of platform devices in array

void **platform_device_put**(struct platform_device * pdev)
destroy a platform device

Parameters

struct platform_device * pdev platform device to free

Description

Free all memory associated with a platform device. This function must _only_ be externally called in error cases. All other usage is a bug.

struct platform_device * **platform_device_alloc**(const char * name, int id)
create a platform device

Parameters

const char * name base name of the device we’re adding

int id instance id

Description

Create a platform device object which can have other objects attached to it, and which will have attached objects freed when it is released.

int **platform_device_add_resources**(struct platform_device * pdev, const struct resource * res, unsigned int num)
add resources to a platform device

Parameters

struct platform_device * pdev platform device allocated by platform_device_alloc to add resources to

const struct resource * res set of resources that needs to be allocated for the device

unsigned int num number of resources

Description

Add a copy of the resources to the platform device. The memory associated with the resources will be freed when the platform device is released.

int **platform_device_add_data**(struct platform_device * pdev, const void * data, size_t size)
add platform-specific data to a platform device

Parameters

struct platform_device * pdev platform device allocated by platform_device_alloc to add resources to

const void * data platform specific data for this platform device

size_t size size of platform specific data

Description

Add a copy of platform specific data to the platform device's platform_data pointer. The memory associated with the platform data will be freed when the platform device is released.

int **platform_device_add_properties**(struct platform_device * pdev, const struct property_entry * properties)
add built-in properties to a platform device

Parameters

struct platform_device * pdev platform device to add properties to

const struct property_entry * properties null terminated array of properties to add

Description

The function will take deep copy of **properties** and attach the copy to the platform device. The memory associated with properties will be freed when the platform device is released.

int **platform_device_add**(struct platform_device * pdev)
add a platform device to device hierarchy

Parameters

struct platform_device * pdev platform device we’re adding

Description

This is part 2 of `platform_device_register()`, though may be called separately _iff_ pdev was allocated by `platform_device_alloc()`.

void **platform_device_del**(struct platform_device * pdev)
remove a platform-level device

Parameters

struct platform_device * pdev platform device we’re removing

Description

Note that this function will also release all memory- and port-based resources owned by the device (**dev->resource**). This function must _only_ be externally called in error cases. All other usage is a bug.

int **platform_device_register**(struct platform_device * pdev)
add a platform-level device

Parameters

struct platform_device * pdev platform device we’re adding

void **platform_device_unregister**(struct platform_device * pdev)
unregister a platform-level device

Parameters

struct platform_device * pdev platform device we’re unregistering

Description

Unregistration is done in 2 steps. First we release all resources and remove it from the subsystem, then we drop reference count by calling `platform_device_put()`.

struct platform_device * **platform_device_register_full**(const struct platform_device_info * pdevinfo)
add a platform-level device with resources and platform-specific data

Parameters

const struct platform_device_info * pdevinfo data used to create device

Description

Returns `struct platform_device` pointer on success, or ERR_PTR() on error.

int **__platform_driver_register**(struct platform_driver * drv, struct module * owner)
register a driver for platform-level devices

Parameters

struct platform_driver * drv platform driver structure

struct module * owner owning module/driver

void **platform_driver_unregister**(struct platform_driver * drv)
unregister a driver for platform-level devices

Parameters

struct platform_driver * drv platform driver structure

int **__platform_driver_probe**(struct platform_driver * drv, int (*probe)(struct platform_device *), struct module * module)
register driver for non-hotpluggable device

Parameters

struct platform_driver * drv platform driver structure

int (*)(struct platform_device *) probe the driver probe routine, probably from an __init section

struct module * module module which will be the owner of the driver

Description

Use this instead of platform_driver_register() when you know the device is not hotpluggable and has already been registered, and you want to remove its run-once probe() infrastructure from memory after the driver has bound to the device.

One typical use for this would be with drivers for controllers integrated into system-on-chip processors, where the controller devices have been configured as part of board setup.

Note that this is incompatible with deferred probing.

Returns zero if the driver registered and bound to a device, else returns a negative error code and with the driver not registered.

struct platform_device * **__platform_create_bundle**(struct platform_driver * driver, int (*probe)(struct platform_device *), struct resource * res, unsigned int n_res, const void * data, size_t size, struct module * module)
register driver and create corresponding device

Parameters

struct platform_driver * driver platform driver structure

int (*)(struct platform_device *) probe the driver probe routine, probably from an __init section

struct resource * res set of resources that needs to be allocated for the device

unsigned int n_res number of resources

const void * data platform specific data for this platform device

size_t size size of platform specific data

struct module * module module which will be the owner of the driver

Description

Use this in legacy-style modules that probe hardware directly and register a single platform device and corresponding platform driver.

Returns `struct platform_device` pointer on success, or ERR_PTR() on error.

int **__platform_register_drivers**(struct platform_driver *const * drivers, unsigned int count, struct module * owner)

register an array of platform drivers

Parameters

struct platform_driver *const * drivers an array of drivers to register

unsigned int count the number of drivers to register

struct module * owner module owning the drivers

Description

Registers platform drivers specified by an array. On failure to register a driver, all previously registered drivers will be unregistered. Callers of this API should use `platform_unregister_drivers()` to unregister drivers in the reverse order.

Return

0 on success or a negative error code on failure.

void **platform_unregister_drivers**(struct platform_driver *const * drivers, unsigned int count)

unregister an array of platform drivers

Parameters

struct platform_driver *const * drivers an array of drivers to unregister

unsigned int count the number of drivers to unregister

Description

Unregisters platform drivers specified by an array. This is typically used to complement an earlier call to platform_register_drivers(). Drivers are unregistered in the reverse order in which they were registered.

struct device * **platform_find_device_by_driver**(struct device * start, const struct device_driver * drv)

Find a platform device with a given driver.

Parameters

struct device * start The device to start the search from.

const struct device_driver * drv The device driver to look for.

int **bus_for_each_dev**(struct bus_type * bus, struct device * start, void * data, int (*fn)(struct device *, void *))
device iterator.

Parameters

struct bus_type * bus bus type.

struct device * start device to start iterating from.

void * data data for the callback.

int (*)(struct device *, void *) fn function to be called for each device.

Description

Iterate over **bus**'s list of devices, and call **fn** for each, passing it **data**. If **start** is not NULL, we use that device to begin iterating from.

We check the return of **fn** each time. If it returns anything other than 0, we break out and return that value.

NOTE

The device that returns a non-zero value is not retained in any way, nor is its refcount incremented. If the caller needs to retain this data, it should do so, and increment the reference count in the supplied callback.

struct device * **bus_find_device**(struct bus_type * bus, struct device * start, const void * data, int (*match)(struct device *dev, const void *data))
device iterator for locating a particular device.

Parameters

struct bus_type * bus bus type

struct device * start Device to begin with

const void * data Data to pass to match function

int (*)(struct device *dev, const void *data) match Callback function to check device

Description

This is similar to the `bus_for_each_dev()` function above, but it returns a reference to a device that is 'found' for later use, as determined by the **match** callback.

The callback should return 0 if the device doesn't match and non-zero if it does. If the callback returns non-zero, this function will return to the caller and not iterate over any more devices.

struct device * **subsys_find_device_by_id**(struct bus_type * subsys, unsigned int id, struct device * hint)
find a device with a specific enumeration number

Parameters

struct bus_type * subsys subsystem

unsigned int id index 'id' in struct device

struct device * hint device to check first

Description

Check the hint's next object and if it is a match return it directly, otherwise, fall back to a full list search. Either way a reference for the returned object is taken.

int **bus_for_each_drv**(struct bus_type * bus, struct device_driver * start, void * data, int (*fn)(struct device_driver *, void *))
driver iterator

Parameters

struct bus_type * bus bus we're dealing with.

struct device_driver * start driver to start iterating on.

void * data data to pass to the callback.

int (*)(struct device_driver *, void *) fn function to call for each driver.

Description

This is nearly identical to the device iterator above. We iterate over each driver that belongs to **bus**, and call **fn** for each. If **fn** returns anything but 0, we break out and return it. If **start** is not NULL, we use it as the head of the list.

NOTE

we don't return the driver that returns a non-zero value, nor do we leave the reference count incremented for that driver. If the caller needs to know that info, it must set it in the callback. It must also be sure to increment the refcount so it doesn't disappear before returning to the caller.

int **bus_rescan_devices**(struct bus_type * bus)
rescan devices on the bus for possible drivers

Parameters

struct bus_type * bus the bus to scan.

Description

This function will look for devices on the bus with no driver attached and rescan it against existing drivers to see if it matches any by calling `device_attach()` for the unbound devices.

int **device_reprobe**(struct device * dev)
remove driver for a device and probe for a new driver

Parameters

struct device * dev the device to reprobe

Description

This function detaches the attached driver (if any) for the given device and restarts the driver probing process. It is intended to use if probing criteria changed during a devices lifetime and driver attachment should change accordingly.

int **bus_register**(struct bus_type * bus)
register a driver-core subsystem

Parameters

struct bus_type * bus bus to register

Description

Once we have that, we register the bus with the kobject infrastructure, then register the children subsystems it has: the devices and drivers that belong to the subsystem.

void **bus_unregister**(struct bus_type * bus)
remove a bus from the system

Parameters

struct bus_type * bus bus.

Description

Unregister the child subsystems and the bus itself. Finally, we call bus_put() to release the refcount

void **subsys_dev_iter_init**(struct subsys_dev_iter * iter, struct bus_type * subsys, struct device * start, const struct device_type * type)
initialize subsys device iterator

Parameters

struct subsys_dev_iter * iter subsys iterator to initialize

struct bus_type * subsys the subsys we wanna iterate over

struct device * start the device to start iterating from, if any

const struct device_type * type device_type of the devices to iterate over, NULL for all

Description

Initialize subsys iterator **iter** such that it iterates over devices of **subsys**. If **start** is set, the list iteration will start there, otherwise if it is NULL, the iteration starts at the beginning of the list.

struct device * **subsys_dev_iter_next**(struct subsys_dev_iter * iter)
iterate to the next device

Parameters

struct subsys_dev_iter * iter subsys iterator to proceed

Description

Proceed **iter** to the next device and return it. Returns NULL if iteration is complete.

The returned device is referenced and won't be released till iterator is proceed to the next device or exited. The caller is free to do whatever it wants to do with the device including calling back into subsys code.

void **subsys_dev_iter_exit**(struct subsys_dev_iter * iter)
finish iteration

Parameters

struct subsys_dev_iter * iter subsys iterator to finish

Description

Finish an iteration. Always call this function after iteration is complete whether the iteration ran till the end or not.

int **subsys_system_register**(struct bus_type * subsys, const struct attribute_group ** groups)
register a subsystem at /sys/devices/system/

Parameters

struct bus_type * subsys system subsystem

const struct attribute_group ** groups default attributes for the root device

Description

All 'system' subsystems have a /sys/devices/system/<name> root device with the name of the subsystem. The root device can carry subsystem- wide attributes. All registered devices are below this single root device and are named after the subsystem with a simple enumeration number appended. The registered devices are not explicitly named; only 'id' in the device needs to be set.

Do not use this interface for anything new, it exists for compatibility with bad ideas only. New subsystems should use plain subsystems; and add the subsystem-wide attributes should be added to the subsystem directory itself and not some create fake root-device placed in /sys/devices/system/<name>.

int **subsys_virtual_register**(struct bus_type * subsys, const struct attribute_group ** groups)
register a subsystem at /sys/devices/virtual/

Parameters

struct bus_type * subsys virtual subsystem

const struct attribute_group ** groups default attributes for the root device

Description

All 'virtual' subsystems have a /sys/devices/system/<name> root device with the name of the subystem. The root device can carry subsystem-wide attributes. All registered devices are below this single root device. There's no restriction on device naming. This is for kernel software constructs which need sysfs interface.

3.3 Device Drivers DMA Management

void **dmam_free_coherent**(struct device * dev, size_t size, void * vaddr, dma_addr_t dma_handle)
Managed dma_free_coherent()

Parameters

struct device * dev Device to free coherent memory for

size_t size Size of allocation

void * vaddr Virtual address of the memory to free

dma_addr_t dma_handle DMA handle of the memory to free

Description

Managed dma_free_coherent().

void * **dmam_alloc_attrs**(struct device * dev, size_t size, dma_addr_t * dma_handle, gfp_t gfp, unsigned long attrs)
Managed dma_alloc_attrs()

Parameters

struct device * dev Device to allocate non_coherent memory for

size_t size Size of allocation

dma_addr_t * dma_handle Out argument for allocated DMA handle

gfp_t gfp Allocation flags

unsigned long attrs Flags in the DMA_ATTR_* namespace.

Description

Managed dma_alloc_attrs(). Memory allocated using this function will be automatically released on driver detach.

Return

Pointer to allocated memory on success, NULL on failure.

bool **dma_can_mmap**(struct device * dev)
check if a given device supports dma_mmap_*

Parameters

struct device * dev device to check

Description

Returns `true` if **dev** supports dma_mmap_coherent() and `dma_mmap_attrs()` to map DMA allocations to userspace.

int **dma_mmap_attrs**(struct device * dev, struct vm_area_struct * vma, void * cpu_addr, dma_addr_t dma_addr, size_t size, unsigned long attrs)
map a coherent DMA allocation into user space

Parameters

struct device * dev valid struct device pointer, or NULL for ISA and EISA-like devices

struct vm_area_struct * vma vm_area_struct describing requested user mapping

void * cpu_addr kernel CPU-view address returned from dma_alloc_attrs

dma_addr_t dma_addr device-view address returned from dma_alloc_attrs

size_t size size of memory originally requested in dma_alloc_attrs

unsigned long attrs attributes of mapping properties requested in dma_alloc_attrs

Description

Map a coherent DMA buffer previously allocated by dma_alloc_attrs into user space. The coherent DMA buffer must not be freed by the driver until the user space mapping has been released.

3.4 Device drivers PnP support

int **pnp_register_protocol**(struct pnp_protocol * protocol)
adds a pnp protocol to the pnp layer

Parameters

struct pnp_protocol * protocol pointer to the corresponding pnp_protocol structure

Ex protocols: ISAPNP, PNPBIOS, etc

void **pnp_unregister_protocol**(struct pnp_protocol * protocol)
removes a pnp protocol from the pnp layer

Parameters

struct pnp_protocol * protocol pointer to the corresponding pnp_protocol structure

struct pnp_dev * **pnp_request_card_device**(struct pnp_card_link * clink, const char * id, struct pnp_dev * from)
Searches for a PnP device under the specified card

Parameters

struct pnp_card_link * clink pointer to the card link, cannot be NULL

const char * id pointer to a PnP ID structure that explains the rules for finding the device

struct pnp_dev * from Starting place to search from. If NULL it will start from the beginning.

void **pnp_release_card_device**(struct pnp_dev * dev)
call this when the driver no longer needs the device

Parameters

struct pnp_dev * dev pointer to the PnP device structure

int **pnp_register_card_driver**(struct pnp_card_driver * drv)
registers a PnP card driver with the PnP Layer

Parameters

struct pnp_card_driver * drv pointer to the driver to register

void **pnp_unregister_card_driver**(struct pnp_card_driver * drv)
unregisters a PnP card driver from the PnP Layer

Parameters

struct pnp_card_driver * drv pointer to the driver to unregister

struct pnp_id * **pnp_add_id**(struct pnp_dev * dev, const char * id)
adds an EISA id to the specified device

Parameters

struct pnp_dev * dev pointer to the desired device

const char * id pointer to an EISA id string

int **pnp_start_dev**(struct pnp_dev * dev)
low-level start of the PnP device

Parameters

struct pnp_dev * dev pointer to the desired device

Description

assumes that resources have already been allocated

int **pnp_stop_dev**(struct pnp_dev * dev)
low-level disable of the PnP device

Parameters

struct pnp_dev * dev pointer to the desired device

Description

does not free resources

int **pnp_activate_dev**(struct pnp_dev * dev)
activates a PnP device for use

Parameters

struct pnp_dev * dev pointer to the desired device

Description

does not validate or set resources so be careful.

int **pnp_disable_dev**(struct pnp_dev * dev)
disables device

Parameters

struct pnp_dev * dev pointer to the desired device

Description

inform the correct pnp protocol so that resources can be used by other devices

int **pnp_is_active**(struct pnp_dev * dev)
Determines if a device is active based on its current resources

Parameters

struct pnp_dev * dev pointer to the desired PnP device

3.5 Userspace IO devices

void **uio_event_notify**(struct uio_info * info)
trigger an interrupt event

Parameters

struct uio_info * info UIO device capabilities

int **__uio_register_device**(struct module * owner, struct device * parent, struct uio_info * info)
register a new userspace IO device

Parameters

struct module * owner module that creates the new device

struct device * parent parent device

struct uio_info * info UIO device capabilities

Description

returns zero on success or a negative error code.

int **__devm_uio_register_device**(struct module * owner, struct device * parent, struct uio_info * info)
Resource managed uio_register_device()

Parameters

struct module * owner module that creates the new device

struct device * parent parent device

struct uio_info * info UIO device capabilities

Description

returns zero on success or a negative error code.

void **uio_unregister_device**(struct uio_info * info)
unregister a industrial IO device

Parameters

struct uio_info * info UIO device capabilities

struct **uio_mem**
description of a UIO memory region

Definition

```
struct uio_mem {
  const char              *name;
  phys_addr_t addr;
  unsigned long           offs;
  resource_size_t size;
  int memtype;
  void __iomem            *internal_addr;
  struct uio_map          *map;
};
```

Members

name name of the memory region for identification

addr address of the device’s memory rounded to page size (phys_addr is used since addr can be logical, virtual, or physical & phys_addr_t should always be large enough to handle any of the address types)

offs offset of device memory within the page

size size of IO (multiple of page size)

memtype type of memory addr points to

internal_addr ioremap-ped version of addr, for driver internal use

map for use by the UIO core only.

struct **uio_port**
description of a UIO port region

Definition

```
struct uio_port {
  const char              *name;
  unsigned long           start;
  unsigned long           size;
  int porttype;
  struct uio_portio       *portio;
};
```

Members

name name of the port region for identification

start start of port region

size size of port region

porttype type of port (see UIO_PORT_* below)

portio for use by the UIO core only.

struct **uio_info**
UIO device capabilities

Definition

```
struct uio_info {
  struct uio_device       *uio_dev;
```

(continues on next page)

(continued from previous page)

```
  const char              *name;
  const char              *version;
  struct uio_mem          mem[MAX_UIO_MAPS];
  struct uio_port         port[MAX_UIO_PORT_REGIONS];
  long irq;
  unsigned long           irq_flags;
  void *priv;
  irqreturn_t (*handler)(int irq, struct uio_info *dev_info);
  int (*mmap)(struct uio_info *info, struct vm_area_struct *vma);
  int (*open)(struct uio_info *info, struct inode *inode);
  int (*release)(struct uio_info *info, struct inode *inode);
  int (*irqcontrol)(struct uio_info *info, s32 irq_on);
};
```

Members

uio_dev the UIO device this info belongs to

name device name

version device driver version

mem list of mappable memory regions, size==0 for end of list

port list of port regions, size==0 for end of list

irq interrupt number or UIO_IRQ_CUSTOM

irq_flags flags for request_irq()

priv optional private data

handler the device’s irq handler

mmap mmap operation for this uio device

open open operation for this uio device

release release operation for this uio device

irqcontrol disable/enable irqs when 0/1 is written to /dev/uioX

CHAPTER

FOUR

IOCTL BASED INTERFACES

ioctl() is the most common way for applications to interface with device drivers. It is flexible and easily extended by adding new commands and can be passed through character devices, block devices as well as sockets and other special file descriptors.

However, it is also very easy to get ioctl command definitions wrong, and hard to fix them later without breaking existing applications, so this documentation tries to help developers get it right.

4.1 Command number definitions

The command number, or request number, is the second argument passed to the ioctl system call. While this can be any 32-bit number that uniquely identifies an action for a particular driver, there are a number of conventions around defining them.

`include/uapi/asm-generic/ioctl.h` provides four macros for defining ioctl commands that follow modern conventions: `_IO`, `_IOR`, `_IOW`, and `_IOWR`. These should be used for all new commands, with the correct parameters:

_IO/_IOR/_IOW/_IOWR The macro name specifies how the argument will be used. It may be a pointer to data to be passed into the kernel (_IOW), out of the kernel (_IOR), or both (_IOWR). _IO can indicate either commands with no argument or those passing an integer value instead of a pointer. It is recommended to only use _IO for commands without arguments, and use pointers for passing data.

type An 8-bit number, often a character literal, specific to a subsystem or driver, and listed in ../userspace-api/ioctl/ioctl-number

nr An 8-bit number identifying the specific command, unique for a give value of 'type'

data_type The name of the data type pointed to by the argument, the command number encodes the `sizeof(data_type)` value in a 13-bit or 14-bit integer, leading to a limit of 8191 bytes for the maximum size of the argument. Note: do not pass sizeof(data_type) type into _IOR/_IOW/IOWR, as that will lead to encoding sizeof(sizeof(data_type)), i.e. sizeof(size_t). _IO does not have a data_type parameter.

4.2 Interface versions

Some subsystems use version numbers in data structures to overload commands with different interpretations of the argument.

This is generally a bad idea, since changes to existing commands tend to break existing applications.

A better approach is to add a new ioctl command with a new number. The old command still needs to be implemented in the kernel for compatibility, but this can be a wrapper around the new implementation.

4.3 Return code

ioctl commands can return negative error codes as documented in errno(3); these get turned into errno values in user space. On success, the return code should be zero. It is also possible but not recommended to return a positive 'long' value.

When the ioctl callback is called with an unknown command number, the handler returns either -ENOTTY or -ENOIOCTLCMD, which also results in -ENOTTY being returned from the system call. Some subsystems return -ENOSYS or -EINVAL here for historic reasons, but this is wrong.

Prior to Linux 5.5, compat_ioctl handlers were required to return -ENOIOCTLCMD in order to use the fallback conversion into native commands. As all subsystems are now responsible for handling compat mode themselves, this is no longer needed, but it may be important to consider when backporting bug fixes to older kernels.

4.4 Timestamps

Traditionally, timestamps and timeout values are passed as `struct timespec` or `struct timeval`, but these are problematic because of incompatible definitions of these structures in user space after the move to 64-bit time_t.

The `struct __kernel_timespec` type can be used instead to be embedded in other data structures when separate second/nanosecond values are desired, or passed to user space directly. This is still not ideal though, as the structure matches neither the kernel's timespec64 nor the user space timespec exactly. The get_timespec64() and put_timespec64() helper functions can be used to ensure that the layout remains compatible with user space and the padding is treated correctly.

As it is cheap to convert seconds to nanoseconds, but the opposite requires an expensive 64-bit division, a simple __u64 nanosecond value can be simpler and more efficient.

Timeout values and timestamps should ideally use CLOCK_MONOTONIC time, as returned by ktime_get_ns() or ktime_get_ts64(). Unlike CLOCK_REALTIME, this makes the timestamps immune from jumping backwards or forwards due to leap second adjustments and clock_settime() calls.

ktime_get_real_ns() can be used for CLOCK_REALTIME timestamps that need to be persistent across a reboot or between multiple machines.

4.5 32-bit compat mode

In order to support 32-bit user space running on a 64-bit machine, each subsystem or driver that implements an ioctl callback handler must also implement the corresponding compat_ioctl handler.

As long as all the rules for data structures are followed, this is as easy as setting the .compat_ioctl pointer to a helper function such as compat_ptr_ioctl() or blkdev_compat_ptr_ioctl().

4.5.1 compat_ptr()

On the s390 architecture, 31-bit user space has ambiguous representations for data pointers, with the upper bit being ignored. When running such a process in compat mode, the compat_ptr() helper must be used to clear the upper bit of a compat_uptr_t and turn it into a valid 64-bit pointer. On other architectures, this macro only performs a cast to a `void __user *` pointer.

In an compat_ioctl() callback, the last argument is an unsigned long, which can be interpreted as either a pointer or a scalar depending on the command. If it is a scalar, then compat_ptr() must not be used, to ensure that the 64-bit kernel behaves the same way as a 32-bit kernel for arguments with the upper bit set.

The compat_ptr_ioctl() helper can be used in place of a custom compat_ioctl file operation for drivers that only take arguments that are pointers to compatible data structures.

4.5.2 Structure layout

Compatible data structures have the same layout on all architectures, avoiding all problematic members:

- `long` and `unsigned long` are the size of a register, so they can be either 32-bit or 64-bit wide and cannot be used in portable data structures. Fixed-length replacements are `__s32`, `__u32`, `__s64` and `__u64`.
- Pointers have the same problem, in addition to requiring the use of compat_ptr(). The best workaround is to use `__u64` in place of pointers, which requires a cast to `uintptr_t` in user space, and the use of u64_to_user_ptr() in the kernel to convert it back into a user pointer.
- On the x86-32 (i386) architecture, the alignment of 64-bit variables is only 32-bit, but they are naturally aligned on most other architectures including x86-64. This means a structure like:

```
struct foo {
    __u32 a;
    __u64 b;
```

(continues on next page)

(continued from previous page)

```
    __u32 c;
};
```

has four bytes of padding between a and b on x86-64, plus another four bytes of padding at the end, but no padding on i386, and it needs a compat_ioctl conversion handler to translate between the two formats.

To avoid this problem, all structures should have their members naturally aligned, or explicit reserved fields added in place of the implicit padding. The `pahole` tool can be used for checking the alignment.

- On ARM OABI user space, structures are padded to multiples of 32-bit, making some structs incompatible with modern EABI kernels if they do not end on a 32-bit boundary.
- On the m68k architecture, struct members are not guaranteed to have an alignment greater than 16-bit, which is a problem when relying on implicit padding.
- Bitfields and enums generally work as one would expect them to, but some properties of them are implementation-defined, so it is better to avoid them completely in ioctl interfaces.
- `char` members can be either signed or unsigned, depending on the architecture, so the __u8 and __s8 types should be used for 8-bit integer values, though char arrays are clearer for fixed-length strings.

4.6 Information leaks

Uninitialized data must not be copied back to user space, as this can cause an information leak, which can be used to defeat kernel address space layout randomization (KASLR), helping in an attack.

For this reason (and for compat support) it is best to avoid any implicit padding in data structures. Where there is implicit padding in an existing structure, kernel drivers must be careful to fully initialize an instance of the structure before copying it to user space. This is usually done by calling memset() before assigning to individual members.

4.7 Subsystem abstractions

While some device drivers implement their own ioctl function, most subsystems implement the same command for multiple drivers. Ideally the subsystem has an .ioctl() handler that copies the arguments from and to user space, passing them into subsystem specific callback functions through normal kernel pointers.

This helps in various ways:

- Applications written for one driver are more likely to work for another one in the same subsystem if there are no subtle differences in the user space ABI.

- The complexity of user space access and data structure layout is done in one place, reducing the potential for implementation bugs.
- It is more likely to be reviewed by experienced developers that can spot problems in the interface when the ioctl is shared between multiple drivers than when it is only used in a single driver.

4.8 Alternatives to ioctl

There are many cases in which ioctl is not the best solution for a problem. Alternatives include:

- System calls are a better choice for a system-wide feature that is not tied to a physical device or constrained by the file system permissions of a character device node
- netlink is the preferred way of configuring any network related objects through sockets.
- debugfs is used for ad-hoc interfaces for debugging functionality that does not need to be exposed as a stable interface to applications.
- sysfs is a good way to expose the state of an in-kernel object that is not tied to a file descriptor.
- configfs can be used for more complex configuration than sysfs
- A custom file system can provide extra flexibility with a simple user interface but adds a lot of complexity to the implementation.

CHAPTER

FIVE

EARLY USERSPACE

5.1 Early userspace support

Last update: 2004-12-20 tlh

“Early userspace” is a set of libraries and programs that provide various pieces of functionality that are important enough to be available while a Linux kernel is coming up, but that don’t need to be run inside the kernel itself.

It consists of several major infrastructure components:

- gen_init_cpio, a program that builds a cpio-format archive containing a root filesystem image. This archive is compressed, and the compressed image is linked into the kernel image.
- initramfs, a chunk of code that unpacks the compressed cpio image midway through the kernel boot process.
- klibc, a userspace C library, currently packaged separately, that is optimized for correctness and small size.

The cpio file format used by initramfs is the “newc” (aka “cpio -H newc”) format, and is documented in the file “buffer-format.txt”. There are two ways to add an early userspace image: specify an existing cpio archive to be used as the image or have the kernel build process build the image from specifications.

5.1.1 CPIO ARCHIVE method

You can create a cpio archive that contains the early userspace image. Your cpio archive should be specified in CONFIG_INITRAMFS_SOURCE and it will be used directly. Only a single cpio file may be specified in CONFIG_INITRAMFS_SOURCE and directory and file names are not allowed in combination with a cpio archive.

5.1.2 IMAGE BUILDING method

The kernel build process can also build an early userspace image from source parts rather than supplying a cpio archive. This method provides a way to create images with root-owned files even though the image was built by an unprivileged user.

The image is specified as one or more sources in CONFIG_INITRAMFS_SOURCE. Sources can be either directories or files - cpio archives are not allowed when building from sources.

A source directory will have it and all of its contents packaged. The specified directory name will be mapped to '/'. When packaging a directory, limited user and group ID translation can be performed. INITRAMFS_ROOT_UID can be set to a user ID that needs to be mapped to user root (0). INITRAMFS_ROOT_GID can be set to a group ID that needs to be mapped to group root (0).

A source file must be directives in the format required by the usr/gen_init_cpio utility (run 'usr/gen_init_cpio -h' to get the file format). The directives in the file will be passed directly to usr/gen_init_cpio.

When a combination of directories and files are specified then the initramfs image will be an aggregate of all of them. In this way a user can create a 'root-image' directory and install all files into it. Because device-special files cannot be created by a unprivileged user, special files can be listed in a 'root-files' file. Both 'root-image' and 'root-files' can be listed in CONFIG_INITRAMFS_SOURCE and a complete early userspace image can be built by an unprivileged user.

As a technical note, when directories and files are specified, the entire CONFIG_INITRAMFS_SOURCE is passed to usr/gen_initramfs_list.sh. This means that CONFIG_INITRAMFS_SOURCE can really be interpreted as any legal argument to gen_initramfs_list.sh. If a directory is specified as an argument then the contents are scanned, uid/gid translation is performed, and usr/gen_init_cpio file directives are output. If a directory is specified as an argument to usr/gen_initramfs_list.sh then the contents of the file are simply copied to the output. All of the output directives from directory scanning and file contents copying are processed by usr/gen_init_cpio.

See also 'usr/gen_initramfs_list.sh -h'.

Where's this all leading?

The klibc distribution contains some of the necessary software to make early userspace useful. The klibc distribution is currently maintained separately from the kernel.

You can obtain somewhat infrequent snapshots of klibc from https://www.kernel.org/pub/linux/libs/klibc/

For active users, you are better off using the klibc git repository, at http://git.kernel.org/?p=libs/klibc/klibc.git

The standalone klibc distribution currently provides three components, in addition to the klibc library:

- ipconfig, a program that configures network interfaces. It can configure them statically, or use DHCP to obtain information dynamically (aka "IP autoconfiguration").
- nfsmount, a program that can mount an NFS filesystem.
- kinit, the "glue" that uses ipconfig and nfsmount to replace the old support for IP autoconfig, mount a filesystem over NFS, and continue system boot using that filesystem as root.

kinit is built as a single statically linked binary to save space.

Eventually, several more chunks of kernel functionality will hopefully move to early userspace:

- Almost all of init/do_mounts* (the beginning of this is already in place)
- ACPI table parsing
- Insert unwieldy subsystem that doesn't really need to be in kernel space here

If kinit doesn't meet your current needs and you've got bytes to burn, the klibc distribution includes a small Bourne-compatible shell (ash) and a number of other utilities, so you can replace kinit and build custom initramfs images that meet your needs exactly.

For questions and help, you can sign up for the early userspace mailing list at http://www.zytor.com/mailman/listinfo/klibc

How does it work?

The kernel has currently 3 ways to mount the root filesystem:

a) all required device and filesystem drivers compiled into the kernel, no initrd. init/main.c:init() will call prepare_namespace() to mount the final root filesystem, based on the root= option and optional init= to run some other init binary than listed at the end of init/main.c:init().

b) some device and filesystem drivers built as modules and stored in an initrd. The initrd must contain a binary '/linuxrc' which is supposed to load these driver modules. It is also possible to mount the final root filesystem via linuxrc and use the pivot_root syscall. The initrd is mounted and executed via prepare_namespace().

c) using initramfs. The call to prepare_namespace() must be skipped. This means that a binary must do all the work. Said binary can be stored into initramfs either via modifying usr/gen_init_cpio.c or via the new initrd format, an cpio archive. It must be called "/init". This binary is responsible to do all the things prepare_namespace() would do.

   To maintain backwards compatibility, the /init binary will only run if it comes via an initramfs cpio archive. If this is not the case, init/main.c:init() will run prepare_namespace() to mount the final root and exec one of the predefined init binaries.

Bryan O'Sullivan <bos@serpentine.com>

5.2 initramfs buffer format

Al Viro, H. Peter Anvin

Last revision: 2002-01-13

Starting with kernel 2.5.x, the old "initial ramdisk" protocol is getting {replaced/complemented} with the new "initial ramfs" (initramfs) protocol. The initramfs contents is passed using the same memory buffer protocol used by the initrd protocol, but the contents is different. The initramfs buffer contains an archive which is expanded into a ramfs filesystem; this document details the format of the initramfs buffer format.

The initramfs buffer format is based around the "newc" or "crc" CPIO formats, and can be created with the cpio(1) utility. The cpio archive can be compressed using gzip(1). One valid version of an initramfs buffer is thus a single .cpio.gz file.

The full format of the initramfs buffer is defined by the following grammar, where:

```
*       is used to indicate "0 or more occurrences of"
(|)     indicates alternatives
+       indicates concatenation
GZIP()  indicates the gzip(1) of the operand
ALGN(n) means padding with null bytes to an n-byte boundary

initramfs  := ("\0" | cpio_archive | cpio_gzip_archive)*

cpio_gzip_archive := GZIP(cpio_archive)

cpio_archive := cpio_file* + (<nothing> | cpio_trailer)

cpio_file := ALGN(4) + cpio_header + filename + "\0" + ALGN(4) + data

cpio_trailer := ALGN(4) + cpio_header + "TRAILER!!!\0" + ALGN(4)
```

In human terms, the initramfs buffer contains a collection of compressed and/or uncompressed cpio archives (in the "newc" or "crc" formats); arbitrary amounts zero bytes (for padding) can be added between members.

The cpio "TRAILER!!!" entry (cpio end-of-archive) is optional, but is not ignored; see "handling of hard links" below.

The structure of the cpio_header is as follows (all fields contain hexadecimal ASCII numbers fully padded with '0' on the left to the full width of the field, for example, the integer 4780 is represented by the ASCII string "000012ac"):

Field name	Field size	Meaning
c_magic	6 bytes	The string “070701” or “070702”
c_ino	8 bytes	File inode number
c_mode	8 bytes	File mode and permissions
c_uid	8 bytes	File uid
c_gid	8 bytes	File gid
c_nlink	8 bytes	Number of links
c_mtime	8 bytes	Modification time
c_filesize	8 bytes	Size of data field
c_maj	8 bytes	Major part of file device number
c_min	8 bytes	Minor part of file device number
c_rmaj	8 bytes	Major part of device node reference
c_rmin	8 bytes	Minor part of device node reference
c_namesize	8 bytes	Length of filename, including final 0
c_chksum	8 bytes	Checksum of data field if c_magic is 070702; otherwise zero

The c_mode field matches the contents of st_mode returned by stat(2) on Linux, and encodes the file type and file permissions.

The c_filesize should be zero for any file which is not a regular file or symlink.

The c_chksum field contains a simple 32-bit unsigned sum of all the bytes in the data field. cpio(1) refers to this as “crc”, which is clearly incorrect (a cyclic redundancy check is a different and significantly stronger integrity check), however, this is the algorithm used.

If the filename is “TRAILER!!!” this is actually an end-of-archive marker; the c_filesize for an end-of-archive marker must be zero.

5.2.1 Handling of hard links

When a nondirectory with c_nlink > 1 is seen, the (c_maj,c_min,c_ino) tuple is looked up in a tuple buffer. If not found, it is entered in the tuple buffer and the entry is created as usual; if found, a hard link rather than a second copy of the file is created. It is not necessary (but permitted) to include a second copy of the file contents; if the file contents is not included, the c_filesize field should be set to zero to indicate no data section follows. If data is present, the previous instance of the file is overwritten; this allows the data-carrying instance of a file to occur anywhere in the sequence (GNU cpio is reported to attach the data to the last instance of a file only.)

c_filesize must not be zero for a symlink.

When a “TRAILER!!!” end-of-archive marker is seen, the tuple buffer is reset. This permits archives which are generated independently to be concatenated.

To combine file data from different sources (without having to regenerate the (c_maj,c_min,c_ino) fields), therefore, either one of the following techniques can be used:

a) Separate the different file data sources with a “TRAILER!!!” end-of-archive marker, or

b) Make sure c_nlink == 1 for all nondirectory entries.

CHAPTER

SIX

CPU AND DEVICE POWER MANAGEMENT

6.1 CPU Idle Time Management

Author Rafael J. Wysocki <rafael.j.wysocki@intel.com>

6.1.1 CPU Idle Time Management Subsystem

Every time one of the logical CPUs in the system (the entities that appear to fetch and execute instructions: hardware threads, if present, or processor cores) is idle after an interrupt or equivalent wakeup event, which means that there are no tasks to run on it except for the special "idle" task associated with it, there is an opportunity to save energy for the processor that it belongs to. That can be done by making the idle logical CPU stop fetching instructions from memory and putting some of the processor's functional units depended on by it into an idle state in which they will draw less power.

However, there may be multiple different idle states that can be used in such a situation in principle, so it may be necessary to find the most suitable one (from the kernel perspective) and ask the processor to use (or "enter") that particular idle state. That is the role of the CPU idle time management subsystem in the kernel, called `CPUIdle`.

The design of `CPUIdle` is modular and based on the code duplication avoidance principle, so the generic code that in principle need not depend on the hardware or platform design details in it is separate from the code that interacts with the hardware. It generally is divided into three categories of functional units: governors responsible for selecting idle states to ask the processor to enter, drivers that pass the governors' decisions on to the hardware and the core providing a common framework for them.

6.1.2 CPU Idle Time Governors

A CPU idle time (CPUIdle) governor is a bundle of policy code invoked when one of the logical CPUs in the system turns out to be idle. Its role is to select an idle state to ask the processor to enter in order to save some energy.

CPUIdle governors are generic and each of them can be used on any hardware platform that the Linux kernel can run on. For this reason, data structures operated on by them cannot depend on any hardware architecture or platform design details as well.

The governor itself is represented by a struct cpuidle_governor object containing four callback pointers, enable, disable, select, reflect, a rating field described below, and a name (string) used for identifying it.

For the governor to be available at all, that object needs to be registered with the CPUIdle core by calling cpuidle_register_governor() with a pointer to it passed as the argument. If successful, that causes the core to add the governor to the global list of available governors and, if it is the only one in the list (that is, the list was empty before) or the value of its rating field is greater than the value of that field for the governor currently in use, or the name of the new governor was passed to the kernel as the value of the cpuidle.governor= command line parameter, the new governor will be used from that point on (there can be only one CPUIdle governor in use at a time). Also, user space can choose the CPUIdle governor to use at run time via sysfs.

Once registered, CPUIdle governors cannot be unregistered, so it is not practical to put them into loadable kernel modules.

The interface between CPUIdle governors and the core consists of four callbacks:

enable

```
int (*enable) (struct cpuidle_driver *drv, struct cpuidle_device␣
↪*dev);
```

The role of this callback is to prepare the governor for handling the (logical) CPU represented by the struct cpuidle_device object pointed to by the dev argument. The struct cpuidle_driver object pointed to by the drv argument represents the CPUIdle driver to be used with that CPU (among other things, it should contain the list of struct cpuidle_state objects representing idle states that the processor holding the given CPU can be asked to enter).

It may fail, in which case it is expected to return a negative error code, and that causes the kernel to run the architecture-specific default code for idle CPUs on the CPU in question instead of CPUIdle until the ->enable() governor callback is invoked for that CPU again.

disable

```
void (*disable) (struct cpuidle_driver *drv, struct cpuidle_device␣
↪*dev);
```

Called to make the governor stop handling the (logical) CPU represented by the struct cpuidle_device object pointed to by the dev argument.

It is expected to reverse any changes made by the `->enable()` callback when it was last invoked for the target CPU, free all memory allocated by that callback and so on.

select

```
int (*select) (struct cpuidle_driver *drv, struct cpuidle_device *dev,
               bool *stop_tick);
```

Called to select an idle state for the processor holding the (logical) CPU represented by the `struct cpuidle_device` object pointed to by the `dev` argument.

The list of idle states to take into consideration is represented by the `states` array of `struct cpuidle_state` objects held by the `struct cpuidle_driver` object pointed to by the `drv` argument (which represents the `CPUIdle` driver to be used with the CPU at hand). The value returned by this callback is interpreted as an index into that array (unless it is a negative error code).

The `stop_tick` argument is used to indicate whether or not to stop the scheduler tick before asking the processor to enter the selected idle state. When the `bool` variable pointed to by it (which is set to `true` before invoking this callback) is cleared to `false`, the processor will be asked to enter the selected idle state without stopping the scheduler tick on the given CPU (if the tick has been stopped on that CPU already, however, it will not be restarted before asking the processor to enter the idle state).

This callback is mandatory (i.e. the `select` callback pointer in `struct cpuidle_governor` must not be `NULL` for the registration of the governor to succeed).

reflect

```
void (*reflect) (struct cpuidle_device *dev, int index);
```

Called to allow the governor to evaluate the accuracy of the idle state selection made by the `->select()` callback (when it was invoked last time) and possibly use the result of that to improve the accuracy of idle state selections in the future.

In addition, `CPUIdle` governors are required to take power management quality of service (PM QoS) constraints on the processor wakeup latency into account when selecting idle states. In order to obtain the current effective PM QoS wakeup latency constraint for a given CPU, a `CPUIdle` governor is expected to pass the number of the CPU to `cpuidle_governor_latency_req()`. Then, the governor's `->select()` callback must not return the index of an indle state whose `exit_latency` value is greater than the number returned by that function.

6.1.3 CPU Idle Time Management Drivers

CPU idle time management (CPUIdle) drivers provide an interface between the other parts of CPUIdle and the hardware.

First of all, a CPUIdle driver has to populate the states array of struct cpuidle_state objects included in the struct cpuidle_driver object representing it. Going forward this array will represent the list of available idle states that the processor hardware can be asked to enter shared by all of the logical CPUs handled by the given driver.

The entries in the states array are expected to be sorted by the value of the target_residency field in struct cpuidle_state in the ascending order (that is, index 0 should correspond to the idle state with the minimum value of target_residency). [Since the target_residency value is expected to reflect the "depth" of the idle state represented by the struct cpuidle_state object holding it, this sorting order should be the same as the ascending sorting order by the idle state "depth".]

Three fields in struct cpuidle_state are used by the existing CPUIdle governors for computations related to idle state selection:

target_residency Minimum time to spend in this idle state including the time needed to enter it (which may be substantial) to save more energy than could be saved by staying in a shallower idle state for the same amount of time, in microseconds.

exit_latency Maximum time it will take a CPU asking the processor to enter this idle state to start executing the first instruction after a wakeup from it, in microseconds.

flags Flags representing idle state properties. Currently, governors only use the CPUIDLE_FLAG_POLLING flag which is set if the given object does not represent a real idle state, but an interface to a software "loop" that can be used in order to avoid asking the processor to enter any idle state at all. [There are other flags used by the CPUIdle core in special situations.]

The enter callback pointer in struct cpuidle_state, which must not be NULL, points to the routine to execute in order to ask the processor to enter this particular idle state:

```
void (*enter) (struct cpuidle_device *dev, struct cpuidle_driver *drv,
               int index);
```

The first two arguments of it point to the struct cpuidle_device object representing the logical CPU running this callback and the struct cpuidle_driver object representing the driver itself, respectively, and the last one is an index of the struct cpuidle_state entry in the driver's states array representing the idle state to ask the processor to enter.

The analogous ->enter_s2idle() callback in struct cpuidle_state is used only for implementing the suspend-to-idle system-wide power management feature. The difference between in and ->enter() is that it must not re-enable interrupts at any point (even temporarily) or attempt to change the states of clock event devices, which the ->enter() callback may do sometimes.

Once the states array has been populated, the number of valid entries in it has to be stored in the state_count field of the struct cpuidle_driver object representing the driver. Moreover, if any entries in the states array represent "coupled"idle states (that is, idle states that can only be asked for if multiple related logical CPUs are idle), the safe_state_index field in struct cpuidle_driver needs to be the index of an idle state that is not "coupled" (that is, one that can be asked for if only one logical CPU is idle).

In addition to that, if the given CPUIdle driver is only going to handle a subset of logical CPUs in the system, the cpumask field in its struct cpuidle_driver object must point to the set (mask) of CPUs that will be handled by it.

A CPUIdle driver can only be used after it has been registered. If there are no "coupled" idle state entries in the driver's states array, that can be accomplished by passing the driver's struct cpuidle_driver object to cpuidle_register_driver(). Otherwise, cpuidle_register() should be used for this purpose.

However, it also is necessary to register struct cpuidle_device objects for all of the logical CPUs to be handled by the given CPUIdle driver with the help of cpuidle_register_device() after the driver has been registered and cpuidle_register_driver(), unlike cpuidle_register(), does not do that automatically. For this reason, the drivers that use cpuidle_register_driver() to register themselves must also take care of registering the struct cpuidle_device objects as needed, so it is generally recommended to use cpuidle_register() for CPUIdle driver registration in all cases.

The registration of a struct cpuidle_device object causes the CPUIdle sysfs interface to be created and the governor's ->enable() callback to be invoked for the logical CPU represented by it, so it must take place after registering the driver that will handle the CPU in question.

CPUIdle drivers and struct cpuidle_device objects can be unregistered when they are not necessary any more which allows some resources associated with them to be released. Due to dependencies between them, all of the struct cpuidle_device objects representing CPUs handled by the given CPUIdle driver must be unregistered, with the help of cpuidle_unregister_device(), before calling cpuidle_unregister_driver() to unregister the driver. Alternatively, cpuidle_unregister() can be called to unregister a CPUIdle driver along with all of the struct cpuidle_device objects representing CPUs handled by it.

CPUIdle drivers can respond to runtime system configuration changes that lead to modifications of the list of available processor idle states (which can happen, for example, when the system's power source is switched from AC to battery or the other way around). Upon a notification of such a change, a CPUIdle driver is expected to call cpuidle_pause_and_lock() to turn CPUIdle off temporarily and then cpuidle_disable_device() for all of the struct cpuidle_device objects representing CPUs affected by that change. Next, it can update its states array in accordance with the new configuration of the system, call cpuidle_enable_device() for all of the relevant struct cpuidle_device objects and invoke cpuidle_resume_and_unlock() to allow CPUIdle to be used again.

6.2 Device Power Management Basics

Author Rafael J. Wysocki <rafael.j.wysocki@intel.com>

Most of the code in Linux is device drivers, so most of the Linux power management (PM) code is also driver-specific. Most drivers will do very little; others, especially for platforms with small batteries (like cell phones), will do a lot.

This writeup gives an overview of how drivers interact with system-wide power management goals, emphasizing the models and interfaces that are shared by everything that hooks up to the driver model core. Read it as background for the domain-specific work you'd do with any specific driver.

6.2.1 Two Models for Device Power Management

Drivers will use one or both of these models to put devices into low-power states:

System Sleep model:

Drivers can enter low-power states as part of entering system-wide low-power states like "suspend" (also known as "suspend-to-RAM"), or (mostly for systems with disks) "hibernation" (also known as "suspend-to-disk").

This is something that device, bus, and class drivers collaborate on by implementing various role-specific suspend and resume methods to cleanly power down hardware and software subsystems, then reactivate them without loss of data.

Some drivers can manage hardware wakeup events, which make the system leave the low-power state. This feature may be enabled or disabled using the relevant `/sys/devices/.../power/wakeup` file (for Ethernet drivers the ioctl interface used by ethtool may also be used for this purpose); enabling it may cost some power usage, but let the whole system enter low-power states more often.

Runtime Power Management model:

Devices may also be put into low-power states while the system is running, independently of other power management activity in principle. However, devices are not generally independent of each other (for example, a parent device cannot be suspended unless all of its child devices have been suspended). Moreover, depending on the bus type the device is on, it may be necessary to carry out some bus-specific operations on the device for this purpose. Devices put into low power states at run time may require special handling during system-wide power transitions (suspend or hibernation).

> For these reasons not only the device driver itself, but also the appropriate subsystem (bus type, device type or device class) driver and the PM core are involved in runtime power management. As in the system sleep power management case, they need to collaborate by implementing various role-specific suspend and resume methods, so that the hardware is cleanly powered down and reactivated without data or service loss.

There's not a lot to be said about those low-power states except that they are very system-specific, and often device-specific. Also, that if enough devices have been put into low-power states (at runtime), the effect may be very similar to entering some system-wide low-power state (system sleep) ···and that synergies exist, so that several drivers using runtime PM might put the system into a state where even deeper power saving options are available.

Most suspended devices will have quiesced all I/O: no more DMA or IRQs (except for wakeup events), no more data read or written, and requests from upstream drivers are no longer accepted. A given bus or platform may have different requirements though.

Examples of hardware wakeup events include an alarm from a real time clock, network wake-on-LAN packets, keyboard or mouse activity, and media insertion or removal (for PCMCIA, MMC/SD, USB, and so on).

6.2.2 Interfaces for Entering System Sleep States

There are programming interfaces provided for subsystems (bus type, device type, device class) and device drivers to allow them to participate in the power management of devices they are concerned with. These interfaces cover both system sleep and runtime power management.

Device Power Management Operations

Device power management operations, at the subsystem level as well as at the device driver level, are implemented by defining and populating objects of type `struct dev_pm_ops` defined in `include/linux/pm.h`. The roles of the methods included in it will be explained in what follows. For now, it should be sufficient to remember that the last three methods are specific to runtime power management while the remaining ones are used during system-wide power transitions.

There also is a deprecated "old" or "legacy" interface for power management operations available at least for some subsystems. This approach does not use `struct dev_pm_ops` objects and it is suitable only for implementing system sleep power management methods in a limited way. Therefore it is not described in this document, so please refer directly to the source code for more information about it.

Subsystem-Level Methods

The core methods to suspend and resume devices reside in `struct dev_pm_ops` pointed to by the `ops` member of `struct dev_pm_domain`, or by the `pm` member of `struct bus_type`, `struct device_type` and `struct class`. They are mostly of interest to the people writing infrastructure for platforms and buses, like PCI or USB, or device type and device class drivers. They also are relevant to the writers of device drivers whose subsystems (PM domains, device types, device classes and bus types) don't provide all power management methods.

Bus drivers implement these methods as appropriate for the hardware and the drivers using it; PCI works differently from USB, and so on. Not many people write subsystem-level drivers; most driver code is a "device driver" that builds on top of bus-specific framework code.

For more information on these driver calls, see the description later; they are called in phases for every device, respecting the parent-child sequencing in the driver model tree.

`/sys/devices/.../power/wakeup` files

All device objects in the driver model contain fields that control the handling of system wakeup events (hardware signals that can force the system out of a sleep state). These fields are initialized by bus or device driver code using `device_set_wakeup_capable()` and `device_set_wakeup_enable()`, defined in `include/linux/pm_wakeup.h`.

The `power.can_wakeup` flag just records whether the device (and its driver) can physically support wakeup events. The `device_set_wakeup_capable()` routine affects this flag. The `power.wakeup` field is a pointer to an object of type `struct wakeup_source` used for controlling whether or not the device should use its system wakeup mechanism and for notifying the PM core of system wakeup events signaled by the device. This object is only present for wakeup-capable devices (i.e. devices whose `can_wakeup` flags are set) and is created (or removed) by `device_set_wakeup_capable()`.

Whether or not a device is capable of issuing wakeup events is a hardware matter, and the kernel is responsible for keeping track of it. By contrast, whether or not a wakeup-capable device should issue wakeup events is a policy decision, and it is managed by user space through a sysfs attribute: the `power/wakeup` file. User space can write the "enabled" or "disabled" strings to it to indicate whether or not, respectively, the device is supposed to signal system wakeup. This file is only present if the `power.wakeup` object exists for the given device and is created (or removed) along with that object, by `device_set_wakeup_capable()`. Reads from the file will return the corresponding string.

The initial value in the `power/wakeup` file is "disabled" for the majority of devices; the major exceptions are power buttons, keyboards, and Ethernet adapters whose WoL (wake-on-LAN) feature has been set up with ethtool. It should also default to "enabled" for devices that don't generate wakeup requests on their own but merely forward wakeup requests from one bus to another (like PCI Express ports).

The `device_may_wakeup()` routine returns true only if the `power.wakeup` object exists and the corresponding `power/wakeup` file contains the "enabled" string. This

information is used by subsystems, like the PCI bus type code, to see whether or not to enable the devices' wakeup mechanisms. If device wakeup mechanisms are enabled or disabled directly by drivers, they also should use `device_may_wakeup()` to decide what to do during a system sleep transition. Device drivers, however, are not expected to call `device_set_wakeup_enable()` directly in any case.

It ought to be noted that system wakeup is conceptually different from "remote wakeup" used by runtime power management, although it may be supported by the same physical mechanism. Remote wakeup is a feature allowing devices in low-power states to trigger specific interrupts to signal conditions in which they should be put into the full-power state. Those interrupts may or may not be used to signal system wakeup events, depending on the hardware design. On some systems it is impossible to trigger them from system sleep states. In any case, remote wakeup should always be enabled for runtime power management for all devices and drivers that support it.

`/sys/devices/.../power/control` files

Each device in the driver model has a flag to control whether it is subject to runtime power management. This flag, `runtime_auto`, is initialized by the bus type (or generally subsystem) code using `pm_runtime_allow()` or `pm_runtime_forbid()`; the default is to allow runtime power management.

The setting can be adjusted by user space by writing either "on" or "auto" to the device's `power/control` sysfs file. Writing "auto" calls `pm_runtime_allow()`, setting the flag and allowing the device to be runtime power-managed by its driver. Writing "on" calls `pm_runtime_forbid()`, clearing the flag, returning the device to full power if it was in a low-power state, and preventing the device from being runtime power-managed. User space can check the current value of the `runtime_auto` flag by reading that file.

The device's `runtime_auto` flag has no effect on the handling of system-wide power transitions. In particular, the device can (and in the majority of cases should and will) be put into a low-power state during a system-wide transition to a sleep state even though its `runtime_auto` flag is clear.

For more information about the runtime power management framework, refer to `Documentation/power/runtime_pm.rst`.

6.2.3 Calling Drivers to Enter and Leave System Sleep States

When the system goes into a sleep state, each device's driver is asked to suspend the device by putting it into a state compatible with the target system state. That's usually some version of "off", but the details are system-specific. Also, wakeup-enabled devices will usually stay partly functional in order to wake the system.

When the system leaves that low-power state, the device's driver is asked to resume it by returning it to full power. The suspend and resume operations always go together, and both are multi-phase operations.

For simple drivers, suspend might quiesce the device using class code and then turn its hardware as "off" as possible during suspend_noirq. The matching resume

calls would then completely reinitialize the hardware before reactivating its class I/O queues.

More power-aware drivers might prepare the devices for triggering system wakeup events.

Call Sequence Guarantees

To ensure that bridges and similar links needing to talk to a device are available when the device is suspended or resumed, the device hierarchy is walked in a bottom-up order to suspend devices. A top-down order is used to resume those devices.

The ordering of the device hierarchy is defined by the order in which devices get registered: a child can never be registered, probed or resumed before its parent; and can't be removed or suspended after that parent.

The policy is that the device hierarchy should match hardware bus topology. [Or at least the control bus, for devices which use multiple busses.] In particular, this means that a device registration may fail if the parent of the device is suspending (i.e. has been chosen by the PM core as the next device to suspend) or has already suspended, as well as after all of the other devices have been suspended. Device drivers must be prepared to cope with such situations.

System Power Management Phases

Suspending or resuming the system is done in several phases. Different phases are used for suspend-to-idle, shallow (standby), and deep ("suspend-to-RAM") sleep states and the hibernation state ("suspend-to-disk"). Each phase involves executing callbacks for every device before the next phase begins. Not all buses or classes support all these callbacks and not all drivers use all the callbacks. The various phases always run after tasks have been frozen and before they are unfrozen. Furthermore, the `*_noirq` phases run at a time when IRQ handlers have been disabled (except for those marked with the IRQF_NO_SUSPEND flag).

All phases use PM domain, bus, type, class or driver callbacks (that is, methods defined in `dev->pm_domain->ops`, `dev->bus->pm`, `dev->type->pm`, `dev->class->pm` or `dev->driver->pm`). These callbacks are regarded by the PM core as mutually exclusive. Moreover, PM domain callbacks always take precedence over all of the other callbacks and, for example, type callbacks take precedence over bus, class and driver callbacks. To be precise, the following rules are used to determine which callback to execute in the given phase:

1. If `dev->pm_domain` is present, the PM core will choose the callback provided by `dev->pm_domain->ops` for execution.
2. Otherwise, if both `dev->type` and `dev->type->pm` are present, the callback provided by `dev->type->pm` will be chosen for execution.
3. Otherwise, if both `dev->class` and `dev->class->pm` are present, the callback provided by `dev->class->pm` will be chosen for execution.
4. Otherwise, if both `dev->bus` and `dev->bus->pm` are present, the callback provided by `dev->bus->pm` will be chosen for execution.

This allows PM domains and device types to override callbacks provided by bus types or device classes if necessary.

The PM domain, type, class and bus callbacks may in turn invoke device- or driver-specific methods stored in `dev->driver->pm`, but they don't have to do that.

If the subsystem callback chosen for execution is not present, the PM core will execute the corresponding method from the `dev->driver->pm` set instead if there is one.

Entering System Suspend

When the system goes into the freeze, standby or memory sleep state, the phases are: `prepare`, `suspend`, `suspend_late`, `suspend_noirq`.

1. The `prepare` phase is meant to prevent races by preventing new devices from being registered; the PM core would never know that all the children of a device had been suspended if new children could be registered at will. [By contrast, from the PM core's perspective, devices may be unregistered at any time.] Unlike the other suspend-related phases, during the `prepare` phase the device hierarchy is traversed top-down.

   After the `->prepare` callback method returns, no new children may be registered below the device. The method may also prepare the device or driver in some way for the upcoming system power transition, but it should not put the device into a low-power state. Moreover, if the device supports runtime power management, the `->prepare` callback method must not update its state in case it is necessary to resume it from runtime suspend later on.

   For devices supporting runtime power management, the return value of the prepare callback can be used to indicate to the PM core that it may safely leave the device in runtime suspend (if runtime-suspended already), provided that all of the device's descendants are also left in runtime suspend. Namely, if the prepare callback returns a positive number and that happens for all of the descendants of the device too, and all of them (including the device itself) are runtime-suspended, the PM core will skip the `suspend`, `suspend_late` and `suspend_noirq` phases as well as all of the corresponding phases of the subsequent device resume for all of these devices. In that case, the `->complete` callback will be the next one invoked after the `->prepare` callback and is entirely responsible for putting the device into a consistent state as appropriate.

   Note that this direct-complete procedure applies even if the device is disabled for runtime PM; only the runtime-PM status matters. It follows that if a device has system-sleep callbacks but does not support runtime PM, then its prepare callback must never return a positive value. This is because all such devices are initially set to runtime-suspended with runtime PM disabled.

   This feature also can be controlled by device drivers by using the `DPM_FLAG_NO_DIRECT_COMPLETE` and `DPM_FLAG_SMART_PREPARE` driver power management flags. [Typically, they are set at the time the driver is probed against the device in question by passing them to the `dev_pm_set_driver_flags()` helper function.] If the first of these flags is set, the PM core will not apply the direct-complete procedure described above to the given device and, consequenty, to any of its ancestors. The second flag,

when set, informs the middle layer code (bus types, device types, PM domains, classes) that it should take the return value of the `->prepare` callback provided by the driver into account and it may only return a positive value from its own `->prepare` callback if the driver's one also has returned a positive value.

2. The `->suspend` methods should quiesce the device to stop it from performing I/O. They also may save the device registers and put it into the appropriate low-power state, depending on the bus type the device is on, and they may enable wakeup events.

   However, for devices supporting runtime power management, the `->suspend` methods provided by subsystems (bus types and PM domains in particular) must follow an additional rule regarding what can be done to the devices before their drivers' `->suspend` methods are called. Namely, they may resume the devices from runtime suspend by calling `pm_runtime_resume()` for them, if that is necessary, but they must not update the state of the devices in any other way at that time (in case the drivers need to resume the devices from runtime suspend in their `->suspend` methods). In fact, the PM core prevents subsystems or drivers from putting devices into runtime suspend at these times by calling `pm_runtime_get_noresume()` before issuing the `->prepare` callback (and calling `pm_runtime_put()` after issuing the `->complete` callback).

3. For a number of devices it is convenient to split suspend into the "quiesce device" and "save device state" phases, in which cases `suspend_late` is meant to do the latter. It is always executed after runtime power management has been disabled for the device in question.

4. The `suspend_noirq` phase occurs after IRQ handlers have been disabled, which means that the driver's interrupt handler will not be called while the callback method is running. The `->suspend_noirq` methods should save the values of the device's registers that weren't saved previously and finally put the device into the appropriate low-power state.

   The majority of subsystems and device drivers need not implement this callback. However, bus types allowing devices to share interrupt vectors, like PCI, generally need it; otherwise a driver might encounter an error during the suspend phase by fielding a shared interrupt generated by some other device after its own device had been set to low power.

At the end of these phases, drivers should have stopped all I/O transactions (DMA, IRQs), saved enough state that they can re-initialize or restore previous state (as needed by the hardware), and placed the device into a low-power state. On many platforms they will gate off one or more clock sources; sometimes they will also switch off power supplies or reduce voltages. [Drivers supporting runtime PM may already have performed some or all of these steps.]

If `device_may_wakeup(dev)()` returns `true`, the device should be prepared for generating hardware wakeup signals to trigger a system wakeup event when the system is in the sleep state. For example, `enable_irq_wake()` might identify GPIO signals hooked up to a switch or other external hardware, and `pci_enable_wake()` does something similar for the PCI PME signal.

If any of these callbacks returns an error, the system won't enter the desired

low-power state. Instead, the PM core will unwind its actions by resuming all the devices that were suspended.

Leaving System Suspend

When resuming from freeze, standby or memory sleep, the phases are: `resume_noirq`, `resume_early`, `resume`, `complete`.

1. The `->resume_noirq` callback methods should perform any actions needed before the driver's interrupt handlers are invoked. This generally means undoing the actions of the `suspend_noirq` phase. If the bus type permits devices to share interrupt vectors, like PCI, the method should bring the device and its driver into a state in which the driver can recognize if the device is the source of incoming interrupts, if any, and handle them correctly.

   For example, the PCI bus type's `->pm.resume_noirq()` puts the device into the full-power state (D0 in the PCI terminology) and restores the standard configuration registers of the device. Then it calls the device driver's `->pm.resume_noirq()` method to perform device-specific actions.

2. The `->resume_early` methods should prepare devices for the execution of the resume methods. This generally involves undoing the actions of the preceding `suspend_late` phase.

3. The `->resume` methods should bring the device back to its operating state, so that it can perform normal I/O. This generally involves undoing the actions of the `suspend` phase.

4. The `complete` phase should undo the actions of the `prepare` phase. For this reason, unlike the other resume-related phases, during the `complete` phase the device hierarchy is traversed bottom-up.

   Note, however, that new children may be registered below the device as soon as the `->resume` callbacks occur; it's not necessary to wait until the `complete` phase runs.

   Moreover, if the preceding `->prepare` callback returned a positive number, the device may have been left in runtime suspend throughout the whole system suspend and resume (its `->suspend`, `->suspend_late`, `->suspend_noirq`, `->resume_noirq`, `->resume_early`, and `->resume` callbacks may have been skipped). In that case, the `->complete` callback is entirely responsible for putting the device into a consistent state after system suspend if necessary. [For example, it may need to queue up a runtime resume request for the device for this purpose.] To check if that is the case, the `->complete` callback can consult the device's `power.direct_complete` flag. If that flag is set when the `->complete` callback is being run then the direct-complete mechanism was used, and special actions may be required to make the device work correctly afterward.

At the end of these phases, drivers should be as functional as they were before suspending: I/O can be performed using DMA and IRQs, and the relevant clocks are gated on.

However, the details here may again be platform-specific. For example, some systems support multiple "run" states, and the mode in effect at the end of re-

sume might not be the one which preceded suspension. That means availability of certain clocks or power supplies changed, which could easily affect how a driver works.

Drivers need to be able to handle hardware which has been reset since all of the suspend methods were called, for example by complete reinitialization. This may be the hardest part, and the one most protected by NDA'd documents and chip errata. It's simplest if the hardware state hasn't changed since the suspend was carried out, but that can only be guaranteed if the target system sleep entered was suspend-to-idle. For the other system sleep states that may not be the case (and usually isn't for ACPI-defined system sleep states, like S3).

Drivers must also be prepared to notice that the device has been removed while the system was powered down, whenever that's physically possible. PCMCIA, MMC, USB, Firewire, SCSI, and even IDE are common examples of busses where common Linux platforms will see such removal. Details of how drivers will notice and handle such removals are currently bus-specific, and often involve a separate thread.

These callbacks may return an error value, but the PM core will ignore such errors since there's nothing it can do about them other than printing them in the system log.

Entering Hibernation

Hibernating the system is more complicated than putting it into sleep states, because it involves creating and saving a system image. Therefore there are more phases for hibernation, with a different set of callbacks. These phases always run after tasks have been frozen and enough memory has been freed.

The general procedure for hibernation is to quiesce all devices ("freeze"), create an image of the system memory while everything is stable, reactivate all devices ("thaw"), write the image to permanent storage, and finally shut down the system ("power off"). The phases used to accomplish this are: `prepare`, `freeze`, `freeze_late`, `freeze_noirq`, `thaw_noirq`, `thaw_early`, `thaw`, `complete`, `prepare`, `poweroff`, `poweroff_late`, `poweroff_noirq`.

1. The `prepare` phase is discussed in the "Entering System Suspend" section above.
2. The `->freeze` methods should quiesce the device so that it doesn't generate IRQs or DMA, and they may need to save the values of device registers. However the device does not have to be put in a low-power state, and to save time it's best not to do so. Also, the device should not be prepared to generate wakeup events.
3. The `freeze_late` phase is analogous to the `suspend_late` phase described earlier, except that the device should not be put into a low-power state and should not be allowed to generate wakeup events.
4. The `freeze_noirq` phase is analogous to the `suspend_noirq` phase discussed earlier, except again that the device should not be put into a low-power state and should not be allowed to generate wakeup events.

At this point the system image is created. All devices should be inactive and the contents of memory should remain undisturbed while this happens, so that the image forms an atomic snapshot of the system state.

5. The `thaw_noirq` phase is analogous to the `resume_noirq` phase discussed earlier. The main difference is that its methods can assume the device is in the same state as at the end of the `freeze_noirq` phase.

6. The `thaw_early` phase is analogous to the `resume_early` phase described above. Its methods should undo the actions of the preceding `freeze_late`, if necessary.

7. The `thaw` phase is analogous to the `resume` phase discussed earlier. Its methods should bring the device back to an operating state, so that it can be used for saving the image if necessary.

8. The `complete` phase is discussed in the "Leaving System Suspend" section above.

At this point the system image is saved, and the devices then need to be prepared for the upcoming system shutdown. This is much like suspending them before putting the system into the suspend-to-idle, shallow or deep sleep state, and the phases are similar.

9. The `prepare` phase is discussed above.

10. The `poweroff` phase is analogous to the `suspend` phase.

11. The `poweroff_late` phase is analogous to the `suspend_late` phase.

12. The `poweroff_noirq` phase is analogous to the `suspend_noirq` phase.

The `->poweroff`, `->poweroff_late` and `->poweroff_noirq` callbacks should do essentially the same things as the `->suspend`, `->suspend_late` and `->suspend_noirq` callbacks, respectively. A notable difference is that they need not store the device register values, because the registers should already have been stored during the `freeze`, `freeze_late` or `freeze_noirq` phases. Also, on many machines the firmware will power-down the entire system, so it is not necessary for the callback to put the device in a low-power state.

Leaving Hibernation

Resuming from hibernation is, again, more complicated than resuming from a sleep state in which the contents of main memory are preserved, because it requires a system image to be loaded into memory and the pre-hibernation memory contents to be restored before control can be passed back to the image kernel.

Although in principle the image might be loaded into memory and the pre-hibernation memory contents restored by the boot loader, in practice this can't be done because boot loaders aren't smart enough and there is no established protocol for passing the necessary information. So instead, the boot loader loads a fresh instance of the kernel, called "the restore kernel", into memory and passes control to it in the usual way. Then the restore kernel reads the system image, restores the pre-hibernation memory contents, and passes control to the image kernel. Thus two different kernel instances are involved in resuming from hibernation. In fact, the restore kernel may be completely different from the image

kernel: a different configuration and even a different version. This has important consequences for device drivers and their subsystems.

To be able to load the system image into memory, the restore kernel needs to include at least a subset of device drivers allowing it to access the storage medium containing the image, although it doesn't need to include all of the drivers present in the image kernel. After the image has been loaded, the devices managed by the boot kernel need to be prepared for passing control back to the image kernel. This is very similar to the initial steps involved in creating a system image, and it is accomplished in the same way, using `prepare`, `freeze`, and `freeze_noirq` phases. However, the devices affected by these phases are only those having drivers in the restore kernel; other devices will still be in whatever state the boot loader left them.

Should the restoration of the pre-hibernation memory contents fail, the restore kernel would go through the "thawing" procedure described above, using the `thaw_noirq`, `thaw_early`, `thaw`, and `complete` phases, and then continue running normally. This happens only rarely. Most often the pre-hibernation memory contents are restored successfully and control is passed to the image kernel, which then becomes responsible for bringing the system back to the working state.

To achieve this, the image kernel must restore the devices' pre-hibernation functionality. The operation is much like waking up from a sleep state (with the memory contents preserved), although it involves different phases: `restore_noirq`, `restore_early`, `restore`, `complete`.

1. The `restore_noirq` phase is analogous to the `resume_noirq` phase.
2. The `restore_early` phase is analogous to the `resume_early` phase.
3. The `restore` phase is analogous to the `resume` phase.
4. The `complete` phase is discussed above.

The main difference from `resume[_early|_noirq]` is that `restore[_early|_noirq]` must assume the device has been accessed and reconfigured by the boot loader or the restore kernel. Consequently, the state of the device may be different from the state remembered from the `freeze`, `freeze_late` and `freeze_noirq` phases. The device may even need to be reset and completely re-initialized. In many cases this difference doesn't matter, so the `->resume[_early|_noirq]` and `->restore[_early|_norq]` method pointers can be set to the same routines. Nevertheless, different callback pointers are used in case there is a situation where it actually does matter.

6.2.4 Power Management Notifiers

There are some operations that cannot be carried out by the power management callbacks discussed above, because the callbacks occur too late or too early. To handle these cases, subsystems and device drivers may register power management notifiers that are called before tasks are frozen and after they have been thawed. Generally speaking, the PM notifiers are suitable for performing actions that either require user space to be available, or at least won't interfere with user space.

For details refer to Suspend/Hibernation Notifiers.

6.2.5 Device Low-Power (suspend) States

Device low-power states aren't standard. One device might only handle "on" and "off", while another might support a dozen different versions of "on" (how many engines are active?), plus a state that gets back to "on" faster than from a full "off".

Some buses define rules about what different suspend states mean. PCI gives one example: after the suspend sequence completes, a non-legacy PCI device may not perform DMA or issue IRQs, and any wakeup events it issues would be issued through the PME# bus signal. Plus, there are several PCI-standard device states, some of which are optional.

In contrast, integrated system-on-chip processors often use IRQs as the wakeup event sources (so drivers would call `enable_irq_wake()`) and might be able to treat DMA completion as a wakeup event (sometimes DMA can stay active too, it'd only be the CPU and some peripherals that sleep).

Some details here may be platform-specific. Systems may have devices that can be fully active in certain sleep states, such as an LCD display that's refreshed using DMA while most of the system is sleeping lightly ⋯and its frame buffer might even be updated by a DSP or other non-Linux CPU while the Linux control processor stays idle.

Moreover, the specific actions taken may depend on the target system state. One target system state might allow a given device to be very operational; another might require a hard shut down with re-initialization on resume. And two different target systems might use the same device in different ways; the aforementioned LCD might be active in one product's "standby", but a different product using the same SOC might work differently.

6.2.6 Device Power Management Domains

Sometimes devices share reference clocks or other power resources. In those cases it generally is not possible to put devices into low-power states individually. Instead, a set of devices sharing a power resource can be put into a low-power state together at the same time by turning off the shared power resource. Of course, they also need to be put into the full-power state together, by turning the shared power resource on. A set of devices with this property is often referred to as a power domain. A power domain may also be nested inside another power domain. The nested domain is referred to as the sub-domain of the parent domain.

Support for power domains is provided through the `pm_domain` field of `struct device`. This field is a pointer to an object of type `struct dev_pm_domain`, defined in `include/linux/pm.h`, providing a set of power management callbacks analogous to the subsystem-level and device driver callbacks that are executed for the given device during all power transitions, instead of the respective subsystem-level callbacks. Specifically, if a device's `pm_domain` pointer is not NULL, the `->suspend()` callback from the object pointed to by it will be executed instead of its subsystem's (e.g. bus type's) `->suspend()` callback and analogously for all of the remaining callbacks. In other words, power management domain callbacks, if defined for the given device, always take precedence over the callbacks provided by the device's subsystem (e.g. bus type).

The support for device power management domains is only relevant to platforms needing to use the same device driver power management callbacks in many different power domain configurations and wanting to avoid incorporating the support for power domains into subsystem-level callbacks, for example by modifying the platform bus type. Other platforms need not implement it or take it into account in any way.

Devices may be defined as IRQ-safe which indicates to the PM core that their runtime PM callbacks may be invoked with disabled interrupts (see `Documentation/power/runtime_pm.rst` for more information). If an IRQ-safe device belongs to a PM domain, the runtime PM of the domain will be disallowed, unless the domain itself is defined as IRQ-safe. However, it makes sense to define a PM domain as IRQ-safe only if all the devices in it are IRQ-safe. Moreover, if an IRQ-safe domain has a parent domain, the runtime PM of the parent is only allowed if the parent itself is IRQ-safe too with the additional restriction that all child domains of an IRQ-safe parent must also be IRQ-safe.

6.2.7 Runtime Power Management

Many devices are able to dynamically power down while the system is still running. This feature is useful for devices that are not being used, and can offer significant power savings on a running system. These devices often support a range of runtime power states, which might use names such as “off”, “sleep”, “idle”, “active”, and so on. Those states will in some cases (like PCI) be partially constrained by the bus the device uses, and will usually include hardware states that are also used in system sleep states.

A system-wide power transition can be started while some devices are in low power states due to runtime power management. The system sleep PM callbacks should recognize such situations and react to them appropriately, but the necessary actions are subsystem-specific.

In some cases the decision may be made at the subsystem level while in other cases the device driver may be left to decide. In some cases it may be desirable to leave a suspended device in that state during a system-wide power transition, but in other cases the device must be put back into the full-power state temporarily, for example so that its system wakeup capability can be disabled. This all depends on the hardware and the design of the subsystem and device driver in question.

If it is necessary to resume a device from runtime suspend during a system-wide transition into a sleep state, that can be done by calling `pm_runtime_resume()` from the `->suspend` callback (or the `->freeze` or `->poweroff` callback for transitions related to hibernation) of either the device’s driver or its subsystem (for example, a bus type or a PM domain). However, subsystems must not otherwise change the runtime status of devices from their `->prepare` and `->suspend` callbacks (or equivalent) before invoking device drivers’ `->suspend` callbacks (or equivalent).

The DPM_FLAG_SMART_SUSPEND Driver Flag

Some bus types and PM domains have a policy to resume all devices from runtime suspend upfront in their ->suspend callbacks, but that may not be really necessary if the device's driver can cope with runtime-suspended devices. The driver can indicate this by setting DPM_FLAG_SMART_SUSPEND in power.driver_flags at probe time, with the assistance of the dev_pm_set_driver_flags() helper routine.

Setting that flag causes the PM core and middle-layer code (bus types, PM domains etc.) to skip the ->suspend_late and ->suspend_noirq callbacks provided by the driver if the device remains in runtime suspend throughout those phases of the system-wide suspend (and similarly for the "freeze" and "poweroff" parts of system hibernation). [Otherwise the same driver callback might be executed twice in a row for the same device, which would not be valid in general.] If the middle-layer system-wide PM callbacks are present for the device then they are responsible for skipping these driver callbacks; if not then the PM core skips them. The subsystem callback routines can determine whether they need to skip the driver callbacks by testing the return value from the dev_pm_skip_suspend() helper function.

In addition, with DPM_FLAG_SMART_SUSPEND set, the driver's ->thaw_noirq and ->thaw_early callbacks are skipped in hibernation if the device remained in runtime suspend throughout the preceding "freeze" transition. Again, if the middle-layer callbacks are present for the device, they are responsible for doing this, otherwise the PM core takes care of it.

The DPM_FLAG_MAY_SKIP_RESUME Driver Flag

During system-wide resume from a sleep state it's easiest to put devices into the full-power state, as explained in Documentation/power/runtime_pm.rst. [Refer to that document for more information regarding this particular issue as well as for information on the device runtime power management framework in general.] However, it often is desirable to leave devices in suspend after system transitions to the working state, especially if those devices had been in runtime suspend before the preceding system-wide suspend (or analogous) transition.

To that end, device drivers can use the DPM_FLAG_MAY_SKIP_RESUME flag to indicate to the PM core and middle-layer code that they allow their "noirq" and "early" resume callbacks to be skipped if the device can be left in suspend after system-wide PM transitions to the working state. Whether or not that is the case generally depends on the state of the device before the given system suspend-resume cycle and on the type of the system transition under way. In particular, the "thaw" and "restore" transitions related to hibernation are not affected by DPM_FLAG_MAY_SKIP_RESUME at all. [All callbacks are issued during the "restore" transition regardless of the flag settings, and whether or not any driver callbacks are skipped during the "thaw" transition depends whether or not the DPM_FLAG_SMART_SUSPEND flag is set (see above). In addition, a device is not allowed to remain in runtime suspend if any of its children will be returned to full power.]

The DPM_FLAG_MAY_SKIP_RESUME flag is taken into account in combination with the power.may_skip_resume status bit set by the PM core during the "suspend" phase of suspend-type transitions. If the driver or the middle layer has a reason to prevent the driver's "noirq"and "early"resume callbacks from being skipped during

the subsequent system resume transition, it should clear power.may_skip_resume in its ->suspend, ->suspend_late or ->suspend_noirq callback. [Note that the drivers setting DPM_FLAG_SMART_SUSPEND need to clear power.may_skip_resume in their ->suspend callback in case the other two are skipped.]

Setting the power.may_skip_resume status bit along with the DPM_FLAG_MAY_SKIP_RESUME flag is necessary, but generally not sufficient, for the driver's "noirq" and "early" resume callbacks to be skipped. Whether or not they should be skipped can be determined by evaluating the dev_pm_skip_resume() helper function.

If that function returns true, the driver's "noirq" and "early" resume callbacks should be skipped and the device's runtime PM status will be set to "suspended" by the PM core. Otherwise, if the device was runtime-suspended during the preceding system-wide suspend transition and its DPM_FLAG_SMART_SUSPEND is set, its runtime PM status will be set to "active" by the PM core. [Hence, the drivers that do not set DPM_FLAG_SMART_SUSPEND should not expect the runtime PM status of their devices to be changed from "suspended" to "active" by the PM core during system-wide resume-type transitions.]

If the DPM_FLAG_MAY_SKIP_RESUME flag is not set for a device, but DPM_FLAG_SMART_SUSPEND is set and the driver's "late" and "noirq" suspend callbacks are skipped, its system-wide "noirq" and "early" resume callbacks, if present, are invoked as usual and the device's runtime PM status is set to "active" by the PM core before enabling runtime PM for it. In that case, the driver must be prepared to cope with the invocation of its system-wide resume callbacks back-to-back with its ->runtime_suspend one (without the intervening ->runtime_resume and system-wide suspend callbacks) and the final state of the device must reflect the "active" runtime PM status in that case. [Note that this is not a problem at all if the driver's ->suspend_late callback pointer points to the same function as its ->runtime_suspend one and its ->resume_early callback pointer points to the same function as the ->runtime_resume one, while none of the other system-wide suspend-resume callbacks of the driver are present, for example.]

Likewise, if DPM_FLAG_MAY_SKIP_RESUME is set for a device, its driver's system-wide "noirq"and "early"resume callbacks may be skipped while its "late"and "noirq" suspend callbacks may have been executed (in principle, regardless of whether or not DPM_FLAG_SMART_SUSPEND is set). In that case, the driver needs to be able to cope with the invocation of its ->runtime_resume callback back-to-back with its "late" and "noirq" suspend ones. [For instance, that is not a concern if the driver sets both DPM_FLAG_SMART_SUSPEND and DPM_FLAG_MAY_SKIP_RESUME and uses the same pair of suspend/resume callback functions for runtime PM and system-wide suspend/resume.]

6.3 Suspend/Hibernation Notifiers

Author Rafael J. Wysocki <rafael.j.wysocki@intel.com>

There are some operations that subsystems or drivers may want to carry out before hibernation/suspend or after restore/resume, but they require the system to be fully functional, so the drivers' and subsystems' `->suspend()` and `->resume()` or even `->prepare()` and `->complete()` callbacks are not suitable for this purpose.

For example, device drivers may want to upload firmware to their devices after resume/restore, but they cannot do it by calling `request_firmware()` from their `->resume()` or `->complete()` callback routines (user land processes are frozen at these points). The solution may be to load the firmware into memory before processes are frozen and upload it from there in the `->resume()` routine. A suspend/hibernation notifier may be used for that.

Subsystems or drivers having such needs can register suspend notifiers that will be called upon the following events by the PM core:

PM_HIBERNATION_PREPARE The system is going to hibernate, tasks will be frozen immediately. This is different from PM_SUSPEND_PREPARE below, because in this case additional work is done between the notifiers and the invocation of PM callbacks for the "freeze" transition.

PM_POST_HIBERNATION The system memory state has been restored from a hibernation image or an error occurred during hibernation. Device restore callbacks have been executed and tasks have been thawed.

PM_RESTORE_PREPARE The system is going to restore a hibernation image. If all goes well, the restored image kernel will issue a PM_POST_HIBERNATION notification.

PM_POST_RESTORE An error occurred during restore from hibernation. Device restore callbacks have been executed and tasks have been thawed.

PM_SUSPEND_PREPARE The system is preparing for suspend.

PM_POST_SUSPEND The system has just resumed or an error occurred during suspend. Device resume callbacks have been executed and tasks have been thawed.

It is generally assumed that whatever the notifiers do for PM_HIBERNATION_PREPARE, should be undone for PM_POST_HIBERNATION. Analogously, operations carried out for PM_SUSPEND_PREPARE should be reversed for PM_POST_SUSPEND.

Moreover, if one of the notifiers fails for the PM_HIBERNATION_PREPARE or PM_SUSPEND_PREPARE event, the notifiers that have already succeeded for that event will be called for PM_POST_HIBERNATION or PM_POST_SUSPEND, respectively.

The hibernation and suspend notifiers are called with pm_mutex held. They are defined in the usual way, but their last argument is meaningless (it is always NULL).

To register and/or unregister a suspend notifier use register_pm_notifier() and unregister_pm_notifier(), respectively (both defined in include/linux/

suspend.h). If you don't need to unregister the notifier, you can also use the pm_notifier() macro defined in include/linux/suspend.h.

6.4 Device Power Management Data Types

struct **dev_pm_ops**
device PM callbacks.

Definition

```
struct dev_pm_ops {
  int (*prepare)(struct device *dev);
  void (*complete)(struct device *dev);
  int (*suspend)(struct device *dev);
  int (*resume)(struct device *dev);

  int (*runtime_resume)(struct device *dev);
  int (*runtime_idle)(struct device *dev);
};
```

Members

prepare The principal role of this callback is to prevent new children of the device from being registered after it has returned (the driver's subsystem and generally the rest of the kernel is supposed to prevent new calls to the probe method from being made too once **prepare()** has succeeded). If **prepare()** detects a situation it cannot handle (e.g. registration of a child already in progress), it may return -EAGAIN, so that the PM core can execute it once again (e.g. after a new child has been registered) to recover from the race condition. This method is executed for all kinds of suspend transitions and is followed by one of the suspend callbacks: **suspend()**, **freeze()**, or **poweroff()**. If the transition is a suspend to memory or standby (that is, not related to hibernation), the return value of **prepare()** may be used to indicate to the PM core to leave the device in runtime suspend if applicable. Namely, if **prepare()** returns a positive number, the PM core will understand that as a declaration that the device appears to be runtime-suspended and it may be left in that state during the entire transition and during the subsequent resume if all of its descendants are left in runtime suspend too. If that happens, **complete()** will be

executed directly after **prepare()** and it must ensure the proper functioning of the device after the system resume. The PM core executes subsystem-level **prepare()** for all devices before starting to invoke suspend callbacks for any of them, so generally devices may be assumed to be functional or to respond to runtime resume requests while **prepare()** is being executed. However, device drivers may NOT assume anything about the availability of user space at that time and it is NOT valid to request firmware from within **prepare()** (it' s too late to do that). It also is NOT valid to allocate substantial amounts of memory from **prepare()** in the GFP_KERNEL mode. [To work around these limitations, drivers may register suspend and hibernation notifiers to be executed before the freezing of tasks.]

complete Undo the changes made by **prepare()**. This method is executed for all kinds of resume transitions, following one of the resume callbacks: **resume()**, **thaw()**, **restore()**. Also called if the state transition fails before the driver' s suspend callback: **suspend()**, **freeze()** or **poweroff()**, can be executed (e.g. if the suspend callback fails for one of the other devices that the PM core has unsuccessfully attempted to suspend earlier). The PM core executes subsystem-level **complete()** after it has executed the appropriate resume callbacks for all devices. If the corresponding **prepare()** at the beginning of the suspend transition returned a positive number and the device was left in runtime suspend (without executing any suspend and resume callbacks for it), **complete()** will be the only callback executed for the device during resume. In that case, **complete()** must be prepared to do whatever is necessary to ensure the proper functioning of the device after the system resume. To this end, **complete()** can check the power.direct_complete flag of the device to learn whether (unset) or not (set) the previous suspend and resume callbacks have been executed for it.

suspend Executed before putting the system into a sleep state in which the contents of main memory are preserved. The exact action to perform depends on the device' s subsystem (PM domain, device type, class or bus type), but generally the device must be quiescent after subsystem-level **suspend()** has returned, so that it doesn' t do any I/O or DMA. Subsystem-level **suspend()** is executed for all devices after invoking subsystem-level **prepare()** for all of them.

resume Executed after waking the system up from a sleep state in which the contents of main memory were preserved. The exact action to perform depends on the device' s subsystem, but generally the driver is expected to start working again, responding to hardware events and software requests (the device itself may be left in a low-power state, waiting for a runtime resume to occur). The state of the device at the time its driver' s **resume()** callback is run depends on the platform and subsystem the device belongs to. On most platforms, there are no restrictions on availability of resources like clocks during **resume()**. Subsystem-level **resume()** is executed for all devices after invoking subsystem-level **resume_noirq()** for all of them.

freeze Hibernation-specific, executed before creating a hibernation image. Analogous to **suspend()**, but it should not enable the device to signal wakeup events or change its power state. The majority of subsystems (with the notable exception of the PCI bus type) expect the driver-level **freeze()** to save the device settings in memory to be used by **restore()** during the subsequent

resume from hibernation. Subsystem-level **freeze()** is executed for all devices after invoking subsystem-level **prepare()** for all of them.

thaw Hibernation-specific, executed after creating a hibernation image OR if the creation of an image has failed. Also executed after a failing attempt to restore the contents of main memory from such an image. Undo the changes made by the preceding **freeze()**, so the device can be operated in the same way as immediately before the call to **freeze()**. Subsystem-level **thaw()** is executed for all devices after invoking subsystem-level **thaw_noirq()** for all of them. It also may be executed directly after **freeze()** in case of a transition error.

poweroff Hibernation-specific, executed after saving a hibernation image. Analogous to **suspend()**, but it need not save the device's settings in memory. Subsystem-level **poweroff()** is executed for all devices after invoking subsystem-level **prepare()** for all of them.

restore Hibernation-specific, executed after restoring the contents of main memory from a hibernation image, analogous to **resume()**.

suspend_late Continue operations started by **suspend()**. For a number of devices **suspend_late()** may point to the same callback routine as the runtime suspend callback.

resume_early Prepare to execute **resume()**. For a number of devices **resume_early()** may point to the same callback routine as the runtime resume callback.

freeze_late Continue operations started by **freeze()**. Analogous to **suspend_late()**, but it should not enable the device to signal wakeup events or change its power state.

thaw_early Prepare to execute **thaw()**. Undo the changes made by the preceding **freeze_late()**.

poweroff_late Continue operations started by **poweroff()**. Analogous to **suspend_late()**, but it need not save the device's settings in memory.

restore_early Prepare to execute **restore()**, analogous to **resume_early()**.

suspend_noirq Complete the actions started by **suspend()**. Carry out any additional operations required for suspending the device that might be racing with its driver's interrupt handler, which is guaranteed not to run while **suspend_noirq()** is being executed. It generally is expected that the device will be in a low-power state (appropriate for the target system sleep state) after subsystem-level **suspend_noirq()** has returned successfully. If the device can generate system wakeup signals and is enabled to wake up the system, it should be configured to do so at that time. However, depending on the platform and device's subsystem, **suspend()** or **suspend_late()** may be allowed to put the device into the low-power state and configure it to generate wakeup signals, in which case it generally is not necessary to define **suspend_noirq()**.

resume_noirq Prepare for the execution of **resume()** by carrying out any operations required for resuming the device that might be racing with its driver's interrupt handler, which is guaranteed not to run while **resume_noirq()** is being executed.

freeze_noirq Complete the actions started by **freeze()**. Carry out any additional operations required for freezing the device that might be racing with its driver's interrupt handler, which is guaranteed not to run while **freeze_noirq()** is being executed. The power state of the device should not be changed by either **freeze()**, or **freeze_late()**, or **freeze_noirq()** and it should not be configured to signal system wakeup by any of these callbacks.

thaw_noirq Prepare for the execution of **thaw()** by carrying out any operations required for thawing the device that might be racing with its driver's interrupt handler, which is guaranteed not to run while **thaw_noirq()** is being executed.

poweroff_noirq Complete the actions started by **poweroff()**. Analogous to **suspend_noirq()**, but it need not save the device's settings in memory.

restore_noirq Prepare for the execution of **restore()** by carrying out any operations required for thawing the device that might be racing with its driver's interrupt handler, which is guaranteed not to run while **restore_noirq()** is being executed. Analogous to **resume_noirq()**.

runtime_suspend Prepare the device for a condition in which it won't be able to communicate with the CPU(s) and RAM due to power management. This need not mean that the device should be put into a low-power state. For example, if the device is behind a link which is about to be turned off, the device may remain at full power. If the device does go to low power and is capable of generating runtime wakeup events, remote wakeup (i.e., a hardware mechanism allowing the device to request a change of its power state via an interrupt) should be enabled for it.

runtime_resume Put the device into the fully active state in response to a wakeup event generated by hardware or at the request of software. If necessary, put the device into the full-power state and restore its registers, so that it is fully operational.

runtime_idle Device appears to be inactive and it might be put into a low-power state if all of the necessary conditions are satisfied. Check these conditions, and return 0 if it's appropriate to let the PM core queue a suspend request for the device.

Description

Several device power state transitions are externally visible, affecting the state of pending I/O queues and (for drivers that touch hardware) interrupts, wakeups, DMA, and other hardware state. There may also be internal transitions to various low-power modes which are transparent to the rest of the driver stack (such as a driver that's ON gating off clocks which are not in active use).

The externally visible transitions are handled with the help of callbacks included in this structure in such a way that, typically, two levels of callbacks are involved. First, the PM core executes callbacks provided by PM domains, device types, classes and bus types. They are the subsystem-level callbacks expected to execute callbacks provided by device drivers, although they may choose not to do that. If the driver callbacks are executed, they have to collaborate with the subsystem-level callbacks to achieve the goals appropriate for the given system transition, given transition phase and the subsystem the device belongs to.

All of the above callbacks, except for **complete()**, return error codes. However, the error codes returned by **resume()**, **thaw()**, **restore()**, **resume_noirq()**, **thaw_noirq()**, and **restore_noirq()**, do not cause the PM core to abort the resume transition during which they are returned. The error codes returned in those cases are only printed to the system logs for debugging purposes. Still, it is recommended that drivers only return error codes from their resume methods in case of an unrecoverable failure (i.e. when the device being handled refuses to resume and becomes unusable) to allow the PM core to be modified in the future, so that it can avoid attempting to handle devices that failed to resume and their children.

It is allowed to unregister devices while the above callbacks are being executed. However, a callback routine MUST NOT try to unregister the device it was called for, although it may unregister children of that device (for example, if it detects that a child was unplugged while the system was asleep).

There also are callbacks related to runtime power management of devices. Again, as a rule these callbacks are executed by the PM core for subsystems (PM domains, device types, classes and bus types) and the subsystem-level callbacks are expected to invoke the driver callbacks. Moreover, the exact actions to be performed by a device driver's callbacks generally depend on the platform and subsystem the device belongs to.

Refer to Documentation/power/runtime_pm.rst for more information about the role of the **runtime_suspend()**, **runtime_resume()** and **runtime_idle()** callbacks in device runtime power management.

struct **dev_pm_domain**
power management domain representation.

Definition

```
struct dev_pm_domain {
  struct dev_pm_ops       ops;
  int (*start)(struct device *dev);
  void (*detach)(struct device *dev, bool power_off);
  int (*activate)(struct device *dev);
  void (*sync)(struct device *dev);
  void (*dismiss)(struct device *dev);
};
```

Members

ops Power management operations associated with this domain.

start Called when a user needs to start the device via the domain.

detach Called when removing a device from the domain.

activate Called before executing probe routines for bus types and drivers.

sync Called after successful driver probe.

dismiss Called after unsuccessful driver probe and after driver removal.

Description

Power domains provide callbacks that are executed during system suspend, hibernation, system resume and during runtime PM transitions instead of subsystem-level and driver-level callbacks.

CHAPTER

SEVEN

THE COMMON CLK FRAMEWORK

Author Mike Turquette <mturquette@ti.com>

This document endeavours to explain the common clk framework details, and how to port a platform over to this framework. It is not yet a detailed explanation of the clock api in include/linux/clk.h, but perhaps someday it will include that information.

7.1 Introduction and interface split

The common clk framework is an interface to control the clock nodes available on various devices today. This may come in the form of clock gating, rate adjustment, muxing or other operations. This framework is enabled with the CONFIG_COMMON_CLK option.

The interface itself is divided into two halves, each shielded from the details of its counterpart. First is the common definition of struct clk which unifies the framework-level accounting and infrastructure that has traditionally been duplicated across a variety of platforms. Second is a common implementation of the clk.h api, defined in drivers/clk/clk.c. Finally there is struct clk_ops, whose operations are invoked by the clk api implementation.

The second half of the interface is comprised of the hardware-specific callbacks registered with struct clk_ops and the corresponding hardware-specific structures needed to model a particular clock. For the remainder of this document any reference to a callback in struct clk_ops, such as .enable or .set_rate, implies the hardware-specific implementation of that code. Likewise, references to struct clk_foo serve as a convenient shorthand for the implementation of the hardware-specific bits for the hypothetical "foo" hardware.

Tying the two halves of this interface together is struct clk_hw, which is defined in struct clk_foo and pointed to within struct clk_core. This allows for easy navigation between the two discrete halves of the common clock interface.

7.2 Common data structures and api

Below is the common struct clk_core definition from drivers/clk/clk.c, modified for brevity:

```
struct clk_core {
        const char              *name;
        const struct clk_ops    *ops;
        struct clk_hw           *hw;
        struct module           *owner;
        struct clk_core         *parent;
        const char              **parent_names;
        struct clk_core         **parents;
        u8                      num_parents;
        u8                      new_parent_index;
        ...
};
```

The members above make up the core of the clk tree topology. The clk api itself defines several driver-facing functions which operate on struct clk. That api is documented in include/linux/clk.h.

Platforms and devices utilizing the common struct clk_core use the struct clk_ops pointer in struct clk_core to perform the hardware-specific parts of the operations defined in clk-provider.h:

```
struct clk_ops {
        int             (*prepare)(struct clk_hw *hw);
        void            (*unprepare)(struct clk_hw *hw);
        int             (*is_prepared)(struct clk_hw *hw);
        void            (*unprepare_unused)(struct clk_hw *hw);
        int             (*enable)(struct clk_hw *hw);
        void            (*disable)(struct clk_hw *hw);
        int             (*is_enabled)(struct clk_hw *hw);
        void            (*disable_unused)(struct clk_hw *hw);
        unsigned long   (*recalc_rate)(struct clk_hw *hw,
                                       unsigned long parent_rate);
        long            (*round_rate)(struct clk_hw *hw,
                                      unsigned long rate,
                                      unsigned long *parent_rate);
        int             (*determine_rate)(struct clk_hw *hw,
                                          struct clk_rate_request *req);
        int             (*set_parent)(struct clk_hw *hw, u8 index);
        u8              (*get_parent)(struct clk_hw *hw);
        int             (*set_rate)(struct clk_hw *hw,
                                    unsigned long rate,
                                    unsigned long parent_rate);
        int             (*set_rate_and_parent)(struct clk_hw *hw,
                                    unsigned long rate,
                                    unsigned long parent_rate,
                                    u8 index);
        unsigned long   (*recalc_accuracy)(struct clk_hw *hw,
                                       unsigned long parent_accuracy);
        int             (*get_phase)(struct clk_hw *hw);
        int             (*set_phase)(struct clk_hw *hw, int degrees);
        void            (*init)(struct clk_hw *hw);
```

(continues on next page)

(continued from previous page)

```
        void            (*debug_init)(struct clk_hw *hw,
                                      struct dentry *dentry);
};
```

7.3 Hardware clk implementations

The strength of the common struct clk_core comes from its .ops and .hw pointers which abstract the details of struct clk from the hardware-specific bits, and vice versa. To illustrate consider the simple gateable clk implementation in drivers/clk/clk-gate.c:

```
struct clk_gate {
        struct clk_hw   hw;
        void __iomem    *reg;
        u8              bit_idx;
        ...
};
```

struct clk_gate contains struct clk_hw hw as well as hardware-specific knowledge about which register and bit controls this clk's gating. Nothing about clock topology or accounting, such as enable_count or notifier_count, is needed here. That is all handled by the common framework code and struct clk_core.

Let's walk through enabling this clk from driver code:

```
struct clk *clk;
clk = clk_get(NULL, "my_gateable_clk");

clk_prepare(clk);
clk_enable(clk);
```

The call graph for clk_enable is very simple:

```
clk_enable(clk);
        clk->ops->enable(clk->hw);
        [resolves to...]
                clk_gate_enable(hw);
                [resolves struct clk gate with to_clk_gate(hw)]
                        clk_gate_set_bit(gate);
```

And the definition of clk_gate_set_bit:

```
static void clk_gate_set_bit(struct clk_gate *gate)
{
        u32 reg;

        reg = __raw_readl(gate->reg);
        reg |= BIT(gate->bit_idx);
        writel(reg, gate->reg);
}
```

Note that to_clk_gate is defined as:

```
#define to_clk_gate(_hw) container_of(_hw, struct clk_gate, hw)
```

This pattern of abstraction is used for every clock hardware representation.

7.4 Supporting your own clk hardware

When implementing support for a new type of clock it is only necessary to include the following header:

```
#include <linux/clk-provider.h>
```

To construct a clk hardware structure for your platform you must define the following:

```
struct clk_foo {
        struct clk_hw hw;
        ... hardware specific data goes here ...
};
```

To take advantage of your data you'll need to support valid operations for your clk:

```
struct clk_ops clk_foo_ops = {
        .enable         = &clk_foo_enable,
        .disable        = &clk_foo_disable,
};
```

Implement the above functions using container_of:

```
#define to_clk_foo(_hw) container_of(_hw, struct clk_foo, hw)

int clk_foo_enable(struct clk_hw *hw)
{
        struct clk_foo *foo;

        foo = to_clk_foo(hw);

        ... perform magic on foo ...

        return 0;
};
```

Below is a matrix detailing which clk_ops are mandatory based upon the hardware capabilities of that clock. A cell marked as "y" means mandatory, a cell marked as "n" implies that either including that callback is invalid or otherwise unnecessary. Empty cells are either optional or must be evaluated on a case-by-case basis.

Table 1: clock hardware characteristics

	gate	change rate	single parent	multiplexer	root
.prepare					
.unprepare					
.enable	y				
.disable	y				
.is_enabled	y				
.recalc_rate		y			
.round_rate		y[1]			
.determine_rate		y[1]			
.set_rate		y			
.set_parent			n	y	n
.get_parent			n	y	n
.recalc_accuracy					
.init					

Finally, register your clock at run-time with a hardware-specific registration function. This function simply populates struct clk_foo's data and then passes the common struct clk parameters to the framework with a call to:

```
clk_register(...)
```

See the basic clock types in `drivers/clk/clk-*.c` for examples.

7.5 Disabling clock gating of unused clocks

Sometimes during development it can be useful to be able to bypass the default disabling of unused clocks. For example, if drivers aren't enabling clocks properly but rely on them being on from the bootloader, bypassing the disabling means that the driver will remain functional while the issues are sorted out.

To bypass this disabling, include "clk_ignore_unused" in the bootargs to the kernel.

[1] either one of round_rate or determine_rate is required.

7.6 Locking

The common clock framework uses two global locks, the prepare lock and the enable lock.

The enable lock is a spinlock and is held across calls to the .enable, .disable operations. Those operations are thus not allowed to sleep, and calls to the clk_enable(), clk_disable() API functions are allowed in atomic context.

For clk_is_enabled() API, it is also designed to be allowed to be used in atomic context. However, it doesn't really make any sense to hold the enable lock in core, unless you want to do something else with the information of the enable state with that lock held. Otherwise, seeing if a clk is enabled is a one-shot read of the enabled state, which could just as easily change after the function returns because the lock is released. Thus the user of this API needs to handle synchronizing the read of the state with whatever they're using it for to make sure that the enable state doesn't change during that time.

The prepare lock is a mutex and is held across calls to all other operations. All those operations are allowed to sleep, and calls to the corresponding API functions are not allowed in atomic context.

This effectively divides operations in two groups from a locking perspective.

Drivers don't need to manually protect resources shared between the operations of one group, regardless of whether those resources are shared by multiple clocks or not. However, access to resources that are shared between operations of the two groups needs to be protected by the drivers. An example of such a resource would be a register that controls both the clock rate and the clock enable/disable state.

The clock framework is reentrant, in that a driver is allowed to call clock framework functions from within its implementation of clock operations. This can for instance cause a .set_rate operation of one clock being called from within the .set_rate operation of another clock. This case must be considered in the driver implementations, but the code flow is usually controlled by the driver in that case.

Note that locking must also be considered when code outside of the common clock framework needs to access resources used by the clock operations. This is considered out of scope of this document.

CHAPTER

EIGHT

BUS-INDEPENDENT DEVICE ACCESSES

Author Matthew Wilcox

Author Alan Cox

8.1 Introduction

Linux provides an API which abstracts performing IO across all busses and devices, allowing device drivers to be written independently of bus type.

8.2 Memory Mapped IO

8.2.1 Getting Access to the Device

The most widely supported form of IO is memory mapped IO. That is, a part of the CPU's address space is interpreted not as accesses to memory, but as accesses to a device. Some architectures define devices to be at a fixed address, but most have some method of discovering devices. The PCI bus walk is a good example of such a scheme. This document does not cover how to receive such an address, but assumes you are starting with one. Physical addresses are of type unsigned long.

This address should not be used directly. Instead, to get an address suitable for passing to the accessor functions described below, you should call `ioremap()`. An address suitable for accessing the device will be returned to you.

After you've finished using the device (say, in your module's exit routine), call `iounmap()` in order to return the address space to the kernel. Most architectures allocate new address space each time you call `ioremap()`, and they can run out unless you call `iounmap()`.

8.2.2 Accessing the device

The part of the interface most used by drivers is reading and writing memory-mapped registers on the device. Linux provides interfaces to read and write 8-bit, 16-bit, 32-bit and 64-bit quantities. Due to a historical accident, these are named byte, word, long and quad accesses. Both read and write accesses are supported; there is no prefetch support at this time.

The functions are named readb(), readw(), readl(), readq(), readb_relaxed(), readw_relaxed(), readl_relaxed(), readq_relaxed(), writeb(), writew(), writel() and writeq().

Some devices (such as framebuffers) would like to use larger transfers than 8 bytes at a time. For these devices, the `memcpy_toio()`, `memcpy_fromio()` and `memset_io()` functions are provided. Do not use memset or memcpy on IO addresses; they are not guaranteed to copy data in order.

The read and write functions are defined to be ordered. That is the compiler is not permitted to reorder the I/O sequence. When the ordering can be compiler optimised, you can use __readb() and friends to indicate the relaxed ordering. Use this with care.

While the basic functions are defined to be synchronous with respect to each other and ordered with respect to each other the busses the devices sit on may themselves have asynchronicity. In particular many authors are burned by the fact that PCI bus writes are posted asynchronously. A driver author must issue a read from the same device to ensure that writes have occurred in the specific cases the author cares. This kind of property cannot be hidden from driver writers in the API. In some cases, the read used to flush the device may be expected to fail (if the card is resetting, for example). In that case, the read should be done from config space, which is guaranteed to soft-fail if the card doesn't respond.

The following is an example of flushing a write to a device when the driver would like to ensure the write's effects are visible prior to continuing execution:

```
static inline void
qla1280_disable_intrs(struct scsi_qla_host *ha)
{
    struct device_reg *reg;

    reg = ha->iobase;
    /* disable risc and host interrupts */
    WRT_REG_WORD(&reg->ictrl, 0);
    /*
     * The following read will ensure that the above write
     * has been received by the device before we return from this
     * function.
     */
    RD_REG_WORD(&reg->ictrl);
    ha->flags.ints_enabled = 0;
}
```

PCI ordering rules also guarantee that PIO read responses arrive after any outstanding DMA writes from that bus, since for some devices the result of a readb() call may signal to the driver that a DMA transaction is complete. In many cases, however, the driver may want to indicate that the next readb() call has no rela-

tion to any previous DMA writes performed by the device. The driver can use readb_relaxed() for these cases, although only some platforms will honor the relaxed semantics. Using the relaxed read functions will provide significant performance benefits on platforms that support it. The qla2xxx driver provides examples of how to use readX_relaxed(). In many cases, a majority of the driver's readX() calls can safely be converted to readX_relaxed() calls, since only a few will indicate or depend on DMA completion.

8.3 Port Space Accesses

8.3.1 Port Space Explained

Another form of IO commonly supported is Port Space. This is a range of addresses separate to the normal memory address space. Access to these addresses is generally not as fast as accesses to the memory mapped addresses, and it also has a potentially smaller address space.

Unlike memory mapped IO, no preparation is required to access port space.

8.3.2 Accessing Port Space

Accesses to this space are provided through a set of functions which allow 8-bit, 16-bit and 32-bit accesses; also known as byte, word and long. These functions are `inb()`, `inw()`, `inl()`, `outb()`, `outw()` and `outl()`.

Some variants are provided for these functions. Some devices require that accesses to their ports are slowed down. This functionality is provided by appending a `_p` to the end of the function. There are also equivalents to memcpy. The `ins()` and `outs()` functions copy bytes, words or longs to the given port.

8.4 Public Functions Provided

phys_addr_t **virt_to_phys**(volatile void * address)
map virtual addresses to physical

Parameters

volatile void * address address to remap

The returned physical address is the physical (CPU) mapping for the memory address given. It is only valid to use this function on addresses directly mapped or allocated via kmalloc.

This function does not give bus mappings for DMA transfers. In almost all conceivable cases a device driver should not be using this function

void * **phys_to_virt**(phys_addr_t address)
map physical address to virtual

Parameters

phys_addr_t address address to remap

The returned virtual address is a current CPU mapping for the memory address given. It is only valid to use this function on addresses that have a kernel mapping

This function does not handle bus mappings for DMA transfers. In almost all conceivable cases a device driver should not be using this function

void __iomem * **ioremap**(resource_size_t offset, unsigned long size)
map bus memory into CPU space

Parameters

resource_size_t offset bus address of the memory

unsigned long size size of the resource to map

Description

ioremap performs a platform specific sequence of operations to make bus memory CPU accessible via the readb/readw/readl/writeb/ writew/writel functions and the other mmio helpers. The returned address is not guaranteed to be usable directly as a virtual address.

If the area you are trying to map is a PCI BAR you should have a look at `pci_iomap()`.

void **iosubmit_cmds512**(void __iomem * __dst, const void * src, size_t count)
copy data to single MMIO location, in 512-bit units

Parameters

void __iomem * __dst destination, in MMIO space (must be 512-bit aligned)

const void * src source

size_t count number of 512 bits quantities to submit

Description

Submit data from kernel space to MMIO space, in units of 512 bits at a time. Order of access is not guaranteed, nor is a memory barrier performed afterwards.

Warning: Do not use this helper unless your driver has checked that the CPU instruction is supported on the platform.

void __iomem * **pci_iomap_range**(struct pci_dev * dev, int bar, unsigned long offset, unsigned long maxlen)
create a virtual mapping cookie for a PCI BAR

Parameters

struct pci_dev * dev PCI device that owns the BAR

int bar BAR number

unsigned long offset map memory at the given offset in BAR

unsigned long maxlen max length of the memory to map

Description

Using this function you will get a __iomem address to your device BAR. You can access it using ioread*() and iowrite*(). These functions hide the details if this is a MMIO or PIO address space and will just do what you expect from them in the correct way.

maxlen specifies the maximum length to map. If you want to get access to the complete BAR from offset to the end, pass `0` here.

void __iomem * **pci_iomap_wc_range**(struct pci_dev * dev, int bar, unsigned long offset, unsigned long maxlen)
create a virtual WC mapping cookie for a PCI BAR

Parameters

struct pci_dev * dev PCI device that owns the BAR

int bar BAR number

unsigned long offset map memory at the given offset in BAR

unsigned long maxlen max length of the memory to map

Description

Using this function you will get a __iomem address to your device BAR. You can access it using ioread*() and iowrite*(). These functions hide the details if this is a MMIO or PIO address space and will just do what you expect from them in the correct way. When possible write combining is used.

maxlen specifies the maximum length to map. If you want to get access to the complete BAR from offset to the end, pass `0` here.

void __iomem * **pci_iomap**(struct pci_dev * dev, int bar, unsigned long maxlen)
create a virtual mapping cookie for a PCI BAR

Parameters

struct pci_dev * dev PCI device that owns the BAR

int bar BAR number

unsigned long maxlen length of the memory to map

Description

Using this function you will get a __iomem address to your device BAR. You can access it using ioread*() and iowrite*(). These functions hide the details if this is a MMIO or PIO address space and will just do what you expect from them in the correct way.

maxlen specifies the maximum length to map. If you want to get access to the complete BAR without checking for its length first, pass `0` here.

void __iomem * **pci_iomap_wc**(struct pci_dev * dev, int bar, unsigned long maxlen)
create a virtual WC mapping cookie for a PCI BAR

Parameters

struct pci_dev * dev PCI device that owns the BAR

int bar BAR number

unsigned long maxlen length of the memory to map

Description

Using this function you will get a __iomem address to your device BAR. You can access it using ioread*() and iowrite*(). These functions hide the details if this is a MMIO or PIO address space and will just do what you expect from them in the correct way. When possible write combining is used.

maxlen specifies the maximum length to map. If you want to get access to the complete BAR without checking for its length first, pass `0` here.

CHAPTER

NINE

DEVICE CONNECTIONS

9.1 Introduction

Devices often have connections to other devices that are outside of the direct child/parent relationship. A serial or network communication controller, which could be a PCI device, may need to be able to get a reference to its PHY component, which could be attached for example to the I2C bus. Some device drivers need to be able to control the clocks or the GPIOs for their devices, and so on.

Device connections are generic descriptions of any type of connection between two separate devices.

Device connections alone do not create a dependency between the two devices. They are only descriptions which are not tied to either of the devices directly. A dependency between the two devices exists only if one of the two endpoint devices requests a reference to the other. The descriptions themselves can be defined in firmware (not yet supported) or they can be built-in.

9.2 Usage

Device connections should exist before device `->probe` callback is called for either endpoint device in the description. If the connections are defined in firmware, this is not a problem. It should be considered if the connection descriptions are "built-in", and need to be added separately.

The connection description consists of the names of the two devices with the connection, i.e. the endpoints, and unique identifier for the connection which is needed if there are multiple connections between the two devices.

After a description exists, the devices in it can request reference to the other endpoint device, or they can request the description itself.

9.3 API

void * **device_connection_find_match**(struct device * dev, const char * con_id, void * data, devcon_match_fn_t match)
Find physical connection to a device

Parameters

struct device * dev Device with the connection

const char * con_id Identifier for the connection

void * data Data for the match function

devcon_match_fn_t match Function to check and convert the connection description

Description

Find a connection with unique identifier **con_id** between **dev** and another device. **match** will be used to convert the connection description to data the caller is expecting to be returned.

struct device * **device_connection_find**(struct device * dev, const char * con_id)
Find two devices connected together

Parameters

struct device * dev Device with the connection

const char * con_id Identifier for the connection

Description

Find a connection with unique identifier **con_id** between **dev** and another device. On success returns handle to the device that is connected to **dev**, with the reference count for the found device incremented. Returns NULL if no matching connection was found, or ERR_PTR(-EPROBE_DEFER) when a connection was found but the other device has not been enumerated yet.

void **device_connection_add**(struct device_connection * con)
Register a connection description

Parameters

struct device_connection * con The connection description to be registered

void **device_connection_remove**(struct device_connection * con)
Unregister connection description

Parameters

struct device_connection * con The connection description to be unregistered

CHAPTER

TEN

BUFFER SHARING AND SYNCHRONIZATION

The dma-buf subsystem provides the framework for sharing buffers for hardware (DMA) access across multiple device drivers and subsystems, and for synchronizing asynchronous hardware access.

This is used, for example, by drm “prime” multi-GPU support, but is of course not limited to GPU use cases.

The three main components of this are: (1) dma-buf, representing a sg_table and exposed to userspace as a file descriptor to allow passing between devices, (2) fence, which provides a mechanism to signal when one device has finished access, and (3) reservation, which manages the shared or exclusive fence(s) associated with the buffer.

10.1 Shared DMA Buffers

This document serves as a guide to device-driver writers on what is the dma-buf buffer sharing API, how to use it for exporting and using shared buffers.

Any device driver which wishes to be a part of DMA buffer sharing, can do so as either the ‘exporter’ of buffers, or the ‘user’ or ‘importer’ of buffers.

Say a driver A wants to use buffers created by driver B, then we call B as the exporter, and A as buffer-user/importer.

The exporter

- implements and manages operations in `struct dma_buf_ops` for the buffer,
- allows other users to share the buffer by using dma_buf sharing APIs,
- manages the details of buffer allocation, wrapped in a `struct dma_buf`,
- decides about the actual backing storage where this allocation happens,
- and takes care of any migration of scatterlist - for all (shared) users of this buffer.

The buffer-user

- is one of (many) sharing users of the buffer.
- doesn’t need to worry about how the buffer is allocated, or where.

- and needs a mechanism to get access to the scatterlist that makes up this buffer in memory, mapped into its own address space, so it can access the same area of memory. This interface is provided by `struct dma_buf_attachment`.

Any exporters or users of the dma-buf buffer sharing framework must have a 'select DMA_SHARED_BUFFER' in their respective Kconfigs.

10.1.1 Userspace Interface Notes

Mostly a DMA buffer file descriptor is simply an opaque object for userspace, and hence the generic interface exposed is very minimal. There's a few things to consider though:

- Since kernel 3.12 the dma-buf FD supports the llseek system call, but only with offset=0 and whence=SEEK_END|SEEK_SET. SEEK_SET is supported to allow the usual size discover pattern size = SEEK_END(0); SEEK_SET(0). Every other llseek operation will report -EINVAL.

  If llseek on dma-buf FDs isn't support the kernel will report -ESPIPE for all cases. Userspace can use this to detect support for discovering the dma-buf size using llseek.

- In order to avoid fd leaks on exec, the FD_CLOEXEC flag must be set on the file descriptor. This is not just a resource leak, but a potential security hole. It could give the newly exec'd application access to buffers, via the leaked fd, to which it should otherwise not be permitted access.

  The problem with doing this via a separate fcntl() call, versus doing it atomically when the fd is created, is that this is inherently racy in a multi-threaded app[3]. The issue is made worse when it is library code opening/creating the file descriptor, as the application may not even be aware of the fd's.

  To avoid this problem, userspace must have a way to request O_CLOEXEC flag be set when the dma-buf fd is created. So any API provided by the exporting driver to create a dmabuf fd must provide a way to let userspace control setting of O_CLOEXEC flag passed in to `dma_buf_fd()`.

- Memory mapping the contents of the DMA buffer is also supported. See the discussion below on CPU Access to DMA Buffer Objects for the full details.

- The DMA buffer FD is also pollable, see Fence Poll Support below for details.

10.1.2 Basic Operation and Device DMA Access

For device DMA access to a shared DMA buffer the usual sequence of operations is fairly simple:

1. The exporter defines his exporter instance using `DEFINE_DMA_BUF_EXPORT_INFO()` and calls `dma_buf_export()` to wrap a private buffer object into a `dma_buf`. It then exports that `dma_buf` to userspace as a file descriptor by calling `dma_buf_fd()`.

2. Userspace passes this file-descriptors to all drivers it wants this buffer to share with: First the filedescriptor is converted to a `dma_buf` using `dma_buf_get()`. Then the buffer is attached to the device using `dma_buf_attach()`.

   Up to this stage the exporter is still free to migrate or reallocate the backing storage.

3. Once the buffer is attached to all devices userspace can initiate DMA access to the shared buffer. In the kernel this is done by calling `dma_buf_map_attachment()` and `dma_buf_unmap_attachment()`.

4. Once a driver is done with a shared buffer it needs to call `dma_buf_detach()` (after cleaning up any mappings) and then release the reference acquired with dma_buf_get by calling `dma_buf_put()`.

For the detailed semantics exporters are expected to implement see `dma_buf_ops`.

10.1.3 CPU Access to DMA Buffer Objects

There are mutliple reasons for supporting CPU access to a dma buffer object:

- Fallback operations in the kernel, for example when a device is connected over USB and the kernel needs to shuffle the data around first before sending it away. Cache coherency is handled by braketing any transactions with calls to `dma_buf_begin_cpu_access()` and `dma_buf_end_cpu_access()` access.

  Since for most kernel internal dma-buf accesses need the entire buffer, a vmap interface is introduced. Note that on very old 32-bit architectures vmalloc space might be limited and result in vmap calls failing.

  Interfaces:: void *dma_buf_vmap(struct dma_buf *dmabuf) void dma_buf_vunmap(struct dma_buf *dmabuf, void *vaddr)

  The vmap call can fail if there is no vmap support in the exporter, or if it runs out of vmalloc space. Fallback to kmap should be implemented. Note that the dma-buf layer keeps a reference count for all vmap access and calls down into the exporter's vmap function only when no vmapping exists, and only unmaps it once. Protection against concurrent vmap/vunmap calls is provided by taking the dma_buf->lock mutex.

- For full compatibility on the importer side with existing userspace interfaces, which might already support mmap'ing buffers. This is needed in many processing pipelines (e.g. feeding a software rendered image into a hardware pipeline, thumbnail creation, snapshots, ⋯). Also, Android's ION framework already supported this and for DMA buffer file descriptors to replace ION buffers mmap support was needed.

  There is no special interfaces, userspace simply calls mmap on the dma-buf fd. But like for CPU access there's a need to braket the actual access, which is handled by the ioctl (DMA_BUF_IOCTL_SYNC). Note that DMA_BUF_IOCTL_SYNC can fail with -EAGAIN or -EINTR, in which case it must be restarted.

  Some systems might need some sort of cache coherency management e.g. when CPU and GPU domains are being accessed through dma-buf

at the same time. To circumvent this problem there are begin/end coherency markers, that forward directly to existing dma-buf device drivers vfunc hooks. Userspace can make use of those markers through the DMA_BUF_IOCTL_SYNC ioctl. The sequence would be used like following:

- mmap dma-buf fd
- for each drawing/upload cycle in CPU 1. SYNC_START ioctl, 2. read/write to mmap area 3. SYNC_END ioctl. This can be repeated as often as you want (with the new data being consumed by say the GPU or the scanout device)
- munmap once you don't need the buffer any more

For correctness and optimal performance, it is always required to use SYNC_START and SYNC_END before and after, respectively, when accessing the mapped address. Userspace cannot rely on coherent access, even when there are systems where it just works without calling these ioctls.

- And as a CPU fallback in userspace processing pipelines.

  Similar to the motivation for kernel cpu access it is again important that the userspace code of a given importing subsystem can use the same interfaces with a imported dma-buf buffer object as with a native buffer object. This is especially important for drm where the userspace part of contemporary OpenGL, X, and other drivers is huge, and reworking them to use a different way to mmap a buffer rather invasive.

  The assumption in the current dma-buf interfaces is that redirecting the initial mmap is all that's needed. A survey of some of the existing subsystems shows that no driver seems to do any nefarious thing like syncing up with outstanding asynchronous processing on the device or allocating special resources at fault time. So hopefully this is good enough, since adding interfaces to intercept pagefaults and allow pte shootdowns would increase the complexity quite a bit.

  Interface::

  int dma_buf_mmap(struct dma_buf *, struct vm_area_struct *, unsigned long);

  If the importing subsystem simply provides a special-purpose mmap call to set up a mapping in userspace, calling do_mmap with dma_buf->file will equally achieve that for a dma-buf object.

10.1.4 Fence Poll Support

To support cross-device and cross-driver synchronization of buffer access implicit fences (represented internally in the kernel with `struct fence`) can be attached to a `dma_buf`. The glue for that and a few related things are provided in the `dma_resv` structure.

Userspace can query the state of these implicitly tracked fences using poll() and related system calls:

- Checking for EPOLLIN, i.e. read access, can be use to query the state of the most recent write or exclusive fence.
- Checking for EPOLLOUT, i.e. write access, can be used to query the state of all attached fences, shared and exclusive ones.

Note that this only signals the completion of the respective fences, i.e. the DMA transfers are complete. Cache flushing and any other necessary preparations before CPU access can begin still need to happen.

10.1.5 Kernel Functions and Structures Reference

struct dma_buf * **dma_buf_export**(const struct dma_buf_export_info * exp_info)
Creates a new dma_buf, and associates an anon file with this buffer, so it can be exported. Also connect the allocator specific data and ops to the buffer. Additionally, provide a name string for exporter; useful in debugging.

Parameters

const struct dma_buf_export_info * exp_info [in] holds all the export related information provided by the exporter. see `struct dma_buf_export_info` for further details.

Description

Returns, on success, a newly created dma_buf object, which wraps the supplied private data and operations for dma_buf_ops. On either missing ops, or error in allocating struct dma_buf, will return negative error.

For most cases the easiest way to create **exp_info** is through the `DEFINE_DMA_BUF_EXPORT_INFO` macro.

int **dma_buf_fd**(struct dma_buf * dmabuf, int flags)
returns a file descriptor for the given dma_buf

Parameters

struct dma_buf * dmabuf [in] pointer to dma_buf for which fd is required.

int flags [in] flags to give to fd

Description

On success, returns an associated ‘fd’. Else, returns error.

struct dma_buf * **dma_buf_get**(int fd)
returns the dma_buf structure related to an fd

Parameters

int fd [in] fd associated with the dma_buf to be returned

Description

On success, returns the dma_buf structure associated with an fd; uses file’s refcounting done by fget to increase refcount. returns ERR_PTR otherwise.

void **dma_buf_put**(struct dma_buf * dmabuf)
decreases refcount of the buffer

Parameters

struct dma_buf * dmabuf [in] buffer to reduce refcount of

Description

Uses file's refcounting done implicitly by fput().

If, as a result of this call, the refcount becomes 0, the 'release' file operation related to this fd is called. It calls `dma_buf_ops.release` vfunc in turn, and frees the memory allocated for dmabuf when exported.

struct dma_buf_attachment * **dma_buf_dynamic_attach**(struct dma_buf * dmabuf, struct device * dev, const struct dma_buf_attach_ops * importer_ops, void * importer_priv)

Add the device to dma_buf's attachments list; optionally, calls attach() of dma_buf_ops to allow device-specific attach functionality

Parameters

struct dma_buf * dmabuf [in] buffer to attach device to.

struct device * dev [in] device to be attached.

const struct dma_buf_attach_ops * importer_ops [in] importer operations for the attachment

void * importer_priv [in] importer private pointer for the attachment

Description

Returns struct dma_buf_attachment pointer for this attachment. Attachments must be cleaned up by calling `dma_buf_detach()`.

A pointer to newly created `dma_buf_attachment` on success, or a negative error code wrapped into a pointer on failure.

Note that this can fail if the backing storage of **dmabuf** is in a place not accessible to **dev**, and cannot be moved to a more suitable place. This is indicated with the error code -EBUSY.

Return

struct dma_buf_attachment * **dma_buf_attach**(struct dma_buf * dmabuf, struct device * dev)

Wrapper for dma_buf_dynamic_attach

Parameters

struct dma_buf * dmabuf [in] buffer to attach device to.

struct device * dev [in] device to be attached.

Description

Wrapper to call `dma_buf_dynamic_attach()` for drivers which still use a static mapping.

void **dma_buf_detach**(struct dma_buf * dmabuf, struct dma_buf_attachment * attach)
Remove the given attachment from dmabuf's attachments list; optionally calls detach() of dma_buf_ops for device-specific detach

Parameters

struct dma_buf * dmabuf [in] buffer to detach from.

struct dma_buf_attachment * attach [in] attachment to be detached; is free'd after this call.

Description

Clean up a device attachment obtained by calling `dma_buf_attach()`.

int **dma_buf_pin**(struct dma_buf_attachment * attach)
Lock down the DMA-buf

Parameters

struct dma_buf_attachment * attach [in] attachment which should be pinned

Return

0 on success, negative error code on failure.

void **dma_buf_unpin**(struct dma_buf_attachment * attach)
Remove lock from DMA-buf

Parameters

struct dma_buf_attachment * attach [in] attachment which should be unpinned

struct sg_table * **dma_buf_map_attachment**(struct dma_buf_attachment * attach, enum dma_data_direction direction)
Returns the scatterlist table of the attachment; mapped into _device_ address space. Is a wrapper for map_dma_buf() of the dma_buf_ops.

Parameters

struct dma_buf_attachment * attach [in] attachment whose scatterlist is to be returned

enum dma_data_direction direction [in] direction of DMA transfer

Description

Returns sg_table containing the scatterlist to be returned; returns ERR_PTR on error. May return -EINTR if it is interrupted by a signal.

A mapping must be unmapped by using `dma_buf_unmap_attachment()`. Note that the underlying backing storage is pinned for as long as a mapping exists, therefore users/importers should not hold onto a mapping for undue amounts of time.

void **dma_buf_unmap_attachment**(struct dma_buf_attachment * attach, struct sg_table * sg_table, enum dma_data_direction direction)
unmaps and decreases usecount of the buffer;might deallocate the scatterlist associated. Is a wrapper for unmap_dma_buf() of dma_buf_ops.

Parameters

struct dma_buf_attachment * attach [in] attachment to unmap buffer from

struct sg_table * sg_table [in] scatterlist info of the buffer to unmap

enum dma_data_direction direction [in] direction of DMA transfer

Description

This unmaps a DMA mapping for **attached** obtained by `dma_buf_map_attachment()`.

void **dma_buf_move_notify**(struct dma_buf * dmabuf)
notify attachments that DMA-buf is moving

Parameters

struct dma_buf * dmabuf [in] buffer which is moving

Description

Informs all attachmenst that they need to destroy and recreated all their mappings.

int **dma_buf_begin_cpu_access**(struct dma_buf * dmabuf, enum dma_data_direction direction)
Must be called before accessing a dma_buf from the cpu in the kernel context. Calls begin_cpu_access to allow exporter-specific preparations. Coherency is only guaranteed in the specified range for the specified access direction.

Parameters

struct dma_buf * dmabuf [in] buffer to prepare cpu access for.

enum dma_data_direction direction [in] length of range for cpu access.

Description

After the cpu access is complete the caller should call `dma_buf_end_cpu_access()`. Only when cpu access is braketed by both calls is it guaranteed to be coherent with other DMA access.

Can return negative error values, returns 0 on success.

int **dma_buf_end_cpu_access**(struct dma_buf * dmabuf, enum dma_data_direction direction)
Must be called after accessing a dma_buf from the cpu in the kernel context. Calls end_cpu_access to allow exporter-specific actions. Coherency is only guaranteed in the specified range for the specified access direction.

Parameters

struct dma_buf * dmabuf [in] buffer to complete cpu access for.

enum dma_data_direction direction [in] length of range for cpu access.

Description

This terminates CPU access started with `dma_buf_begin_cpu_access()`.

Can return negative error values, returns 0 on success.

int **dma_buf_mmap**(struct dma_buf * dmabuf, struct vm_area_struct * vma, unsigned long pgoff)
Setup up a userspace mmap with the given vma

Parameters

struct dma_buf * dmabuf [in] buffer that should back the vma

struct vm_area_struct * vma [in] vma for the mmap

unsigned long pgoff [in] offset in pages where this mmap should start within the dma-buf buffer.

Description

This function adjusts the passed in vma so that it points at the file of the dma_buf operation. It also adjusts the starting pgoff and does bounds checking on the size of the vma. Then it calls the exporters mmap function to set up the mapping.

Can return negative error values, returns 0 on success.

void * **dma_buf_vmap**(struct dma_buf * dmabuf)
Create virtual mapping for the buffer object into kernel address space. Same restrictions as for vmap and friends apply.

Parameters

struct dma_buf * dmabuf [in] buffer to vmap

Description

This call may fail due to lack of virtual mapping address space. These calls are optional in drivers. The intended use for them is for mapping objects linear in kernel space for high use objects. Please attempt to use kmap/kunmap before thinking about these interfaces.

Returns NULL on error.

void **dma_buf_vunmap**(struct dma_buf * dmabuf, void * vaddr)
Unmap a vmap obtained by dma_buf_vmap.

Parameters

struct dma_buf * dmabuf [in] buffer to vunmap

void * vaddr [in] vmap to vunmap

struct **dma_buf_ops**
operations possible on struct dma_buf

Definition

```
struct dma_buf_ops {
  bool cache_sgt_mapping;
  int (*attach)(struct dma_buf *, struct dma_buf_attachment *);
  void (*detach)(struct dma_buf *, struct dma_buf_attachment *);
  int (*pin)(struct dma_buf_attachment *attach);
  void (*unpin)(struct dma_buf_attachment *attach);
  struct sg_table * (*map_dma_buf)(struct dma_buf_attachment *, enum dma_
↪data_direction);
  void (*unmap_dma_buf)(struct dma_buf_attachment *,struct sg_table *,␣
↪enum dma_data_direction);
```

(continues on next page)

(continued from previous page)

```
  void (*release)(struct dma_buf *);
  int (*begin_cpu_access)(struct dma_buf *, enum dma_data_direction);
  int (*end_cpu_access)(struct dma_buf *, enum dma_data_direction);
  int (*mmap)(struct dma_buf *, struct vm_area_struct *vma);
  void *(*vmap)(struct dma_buf *);
  void (*vunmap)(struct dma_buf *, void *vaddr);
};
```

Members

cache_sgt_mapping If true the framework will cache the first mapping made for each attachment. This avoids creating mappings for attachments multiple times.

attach This is called from `dma_buf_attach()` to make sure that a given `dma_buf_attachment.dev` can access the provided `dma_buf`. Exporters which support buffer objects in special locations like VRAM or device-specific carve-out areas should check whether the buffer could be move to system memory (or directly accessed by the provided device), and otherwise need to fail the attach operation.

The exporter should also in general check whether the current allocation fulfills the DMA constraints of the new device. If this is not the case, and the allocation cannot be moved, it should also fail the attach operation.

Any exporter-private housekeeping data can be stored in the `dma_buf_attachment.priv` pointer.

This callback is optional.

Returns:

0 on success, negative error code on failure. It might return -EBUSY to signal that backing storage is already allocated and incompatible with the requirements of requesting device.

detach This is called by `dma_buf_detach()` to release a `dma_buf_attachment`. Provided so that exporters can clean up any housekeeping for an `dma_buf_attachment`.

This callback is optional.

pin This is called by dma_buf_pin and lets the exporter know that the DMA-buf can't be moved any more.

This is called with the dmabuf->resv object locked and is mutual exclusive with **cache_sgt_mapping**.

This callback is optional and should only be used in limited use cases like scanout and not for temporary pin operations.

Returns:

0 on success, negative error code on failure.

unpin This is called by dma_buf_unpin and lets the exporter know that the DMA-buf can be moved again.

This is called with the dmabuf->resv object locked and is mutual exclusive with **cache_sgt_mapping**.

This callback is optional.

map_dma_buf This is called by `dma_buf_map_attachment()` and is used to map a shared `dma_buf` into device address space, and it is mandatory. It can only be called if **attach** has been called successfully.

This call may sleep, e.g. when the backing storage first needs to be allocated, or moved to a location suitable for all currently attached devices.

Note that any specific buffer attributes required for this function should get added to device_dma_parameters accessible via `device.dma_params` from the `dma_buf_attachment`. The **attach** callback should also check these constraints.

If this is being called for the first time, the exporter can now choose to scan through the list of attachments for this buffer, collate the requirements of the attached devices, and choose an appropriate backing storage for the buffer.

Based on enum dma_data_direction, it might be possible to have multiple users accessing at the same time (for reading, maybe), or any other kind of sharing that the exporter might wish to make available to buffer-users.

This is always called with the dmabuf->resv object locked when the dynamic_mapping flag is true.

Returns:

A `sg_table` scatter list of or the backing storage of the DMA buffer, already mapped into the device address space of the `device` attached with the provided `dma_buf_attachment`.

On failure, returns a negative error value wrapped into a pointer. May also return -EINTR when a signal was received while being blocked.

unmap_dma_buf This is called by `dma_buf_unmap_attachment()` and should unmap and release the `sg_table` allocated in **map_dma_buf**, and it is mandatory. For static dma_buf handling this might also unpins the backing storage if this is the last mapping of the DMA buffer.

release Called after the last dma_buf_put to release the `dma_buf`, and mandatory.

begin_cpu_access This is called from `dma_buf_begin_cpu_access()` and allows the exporter to ensure that the memory is actually available for cpu access - the exporter might need to allocate or swap-in and pin the backing storage. The exporter also needs to ensure that cpu access is coherent for the access direction. The direction can be used by the exporter to optimize the cache flushing, i.e. access with a different direction (read instead of write) might return stale or even bogus data (e.g. when the exporter needs to copy the data to temporary storage).

This callback is optional.

FIXME: This is both called through the DMA_BUF_IOCTL_SYNC command from userspace (where storage shouldn't be pinned to avoid handing de-factor mlock rights to userspace) and for the kernel-internal users of the various kmap interfaces, where the backing storage must be pinned to guarantee

that the atomic kmap calls can succeed. Since there's no in-kernel users of the kmap interfaces yet this isn't a real problem.

Returns:

0 on success or a negative error code on failure. This can for example fail when the backing storage can't be allocated. Can also return -ERESTARTSYS or -EINTR when the call has been interrupted and needs to be restarted.

end_cpu_access This is called from `dma_buf_end_cpu_access()` when the importer is done accessing the CPU. The exporter can use this to flush caches and unpin any resources pinned in **begin_cpu_access**. The result of any dma_buf kmap calls after end_cpu_access is undefined.

This callback is optional.

Returns:

0 on success or a negative error code on failure. Can return -ERESTARTSYS or -EINTR when the call has been interrupted and needs to be restarted.

mmap This callback is used by the `dma_buf_mmap()` function

Note that the mapping needs to be incoherent, userspace is expected to braket CPU access using the DMA_BUF_IOCTL_SYNC interface.

Because dma-buf buffers have invariant size over their lifetime, the dma-buf core checks whether a vma is too large and rejects such mappings. The exporter hence does not need to duplicate this check. Drivers do not need to check this themselves.

If an exporter needs to manually flush caches and hence needs to fake coherency for mmap support, it needs to be able to zap all the ptes pointing at the backing storage. Now linux mm needs a struct address_space associated with the struct file stored in vma->vm_file to do that with the function unmap_mapping_range. But the dma_buf framework only backs every dma_buf fd with the anon_file struct file, i.e. all dma_bufs share the same file.

Hence exporters need to setup their own file (and address_space) association by setting vma->vm_file and adjusting vma->vm_pgoff in the dma_buf mmap callback. In the specific case of a gem driver the exporter could use the shmem file already provided by gem (and set vm_pgoff = 0). Exporters can then zap ptes by unmapping the corresponding range of the struct address_space associated with their own file.

This callback is optional.

Returns:

0 on success or a negative error code on failure.

vmap [optional] creates a virtual mapping for the buffer into kernel address space. Same restrictions as for vmap and friends apply.

vunmap [optional] unmaps a vmap from the buffer

struct **dma_buf**
shared buffer object

Definition

```
struct dma_buf {
  size_t size;
  struct file *file;
  struct list_head attachments;
  const struct dma_buf_ops *ops;
  struct mutex lock;
  unsigned vmapping_counter;
  void *vmap_ptr;
  const char *exp_name;
  const char *name;
  struct module *owner;
  struct list_head list_node;
  void *priv;
  struct dma_resv *resv;
  wait_queue_head_t poll;
  struct dma_buf_poll_cb_t {
    struct dma_fence_cb cb;
    wait_queue_head_t *poll;
    __poll_t active;
  } cb_excl, cb_shared;
};
```

Members

size size of the buffer

file file pointer used for sharing buffers across, and for refcounting.

attachments list of dma_buf_attachment that denotes all devices attached, protected by dma_resv lock.

ops dma_buf_ops associated with this buffer object.

lock used internally to serialize list manipulation, attach/detach and vmap/unmap

vmapping_counter used internally to refcnt the vmaps

vmap_ptr the current vmap ptr if vmapping_counter > 0

exp_name name of the exporter; useful for debugging.

name userspace-provided name; useful for accounting and debugging, protected by **resv**.

owner pointer to exporter module; used for refcounting when exporter is a kernel module.

list_node node for dma_buf accounting and debugging.

priv exporter specific private data for this buffer object.

resv reservation object linked to this dma-buf

poll for userspace poll support

cb_excl for userspace poll support

cb_shared for userspace poll support

Description

This represents a shared buffer, created by calling `dma_buf_export()`. The userspace representation is a normal file descriptor, which can be created by calling `dma_buf_fd()`.

Shared dma buffers are reference counted using `dma_buf_put()` and `get_dma_buf()`.

Device DMA access is handled by the separate `struct dma_buf_attachment`.

struct **dma_buf_attach_ops**
importer operations for an attachment

Definition

```
struct dma_buf_attach_ops {
  bool allow_peer2peer;
  void (*move_notify)(struct dma_buf_attachment *attach);
};
```

Members

allow_peer2peer If this is set to true the importer must be able to handle peer resources without struct pages.

move_notify [optional] notification that the DMA-buf is moving

If this callback is provided the framework can avoid pinning the backing store while mappings exists.

This callback is called with the lock of the reservation object associated with the dma_buf held and the mapping function must be called with this lock held as well. This makes sure that no mapping is created concurrently with an ongoing move operation.

Mappings stay valid and are not directly affected by this callback. But the DMA-buf can now be in a different physical location, so all mappings should be destroyed and re-created as soon as possible.

New mappings can be created after this callback returns, and will point to the new location of the DMA-buf.

Description

Attachment operations implemented by the importer.

struct **dma_buf_attachment**
holds device-buffer attachment data

Definition

```
struct dma_buf_attachment {
  struct dma_buf *dmabuf;
  struct device *dev;
  struct list_head node;
  struct sg_table *sgt;
  enum dma_data_direction dir;
  bool peer2peer;
  const struct dma_buf_attach_ops *importer_ops;
  void *importer_priv;
```

(continues on next page)

(continued from previous page)

```
  void *priv;
};
```

Members

dmabuf buffer for this attachment.

dev device attached to the buffer.

node list of dma_buf_attachment, protected by dma_resv lock of the dmabuf.

sgt cached mapping.

dir direction of cached mapping.

peer2peer true if the importer can handle peer resources without pages.

importer_ops importer operations for this attachment, if provided dma_buf_map/unmap_attachment() must be called with the dma_resv lock held.

importer_priv importer specific attachment data.

priv exporter specific attachment data.

Description

This structure holds the attachment information between the dma_buf buffer and its user device(s). The list contains one attachment struct per device attached to the buffer.

An attachment is created by calling `dma_buf_attach()`, and released again by calling `dma_buf_detach()`. The DMA mapping itself needed to initiate a transfer is created by `dma_buf_map_attachment()` and freed again by calling `dma_buf_unmap_attachment()`.

struct **dma_buf_export_info**
holds information needed to export a dma_buf

Definition

```
struct dma_buf_export_info {
  const char *exp_name;
  struct module *owner;
  const struct dma_buf_ops *ops;
  size_t size;
  int flags;
  struct dma_resv *resv;
  void *priv;
};
```

Members

exp_name name of the exporter - useful for debugging.

owner pointer to exporter module - used for refcounting kernel module

ops Attach allocator-defined dma buf ops to the new buffer

size Size of the buffer

flags mode flags for the file

resv reservation-object, NULL to allocate default one

priv Attach private data of allocator to this buffer

Description

This structure holds the information required to export the buffer. Used with `dma_buf_export()` only.

DEFINE_DMA_BUF_EXPORT_INFO(name)
helper macro for exporters

Parameters

name export-info name

Description

DEFINE_DMA_BUF_EXPORT_INFO macro defines the `struct dma_buf_export_info`, zeroes it out and pre-populates exp_name in it.

void **get_dma_buf**(struct dma_buf * dmabuf)
convenience wrapper for get_file.

Parameters

struct dma_buf * dmabuf [in] pointer to dma_buf

Description

Increments the reference count on the dma-buf, needed in case of drivers that either need to create additional references to the dmabuf on the kernel side. For example, an exporter that needs to keep a dmabuf ptr so that subsequent exports don't create a new dmabuf.

bool **dma_buf_is_dynamic**(struct dma_buf * dmabuf)
check if a DMA-buf uses dynamic mappings.

Parameters

struct dma_buf * dmabuf the DMA-buf to check

Description

Returns true if a DMA-buf exporter wants to be called with the dma_resv locked for the map/unmap callbacks, false if it doesn't wants to be called with the lock held.

bool **dma_buf_attachment_is_dynamic**(struct dma_buf_attachment * attach)
check if a DMA-buf attachment uses dynamic mappinsg

Parameters

struct dma_buf_attachment * attach the DMA-buf attachment to check

Description

Returns true if a DMA-buf importer wants to call the map/unmap functions with the dma_resv lock held.

10.2 Reservation Objects

The reservation object provides a mechanism to manage shared and exclusive fences associated with a buffer. A reservation object can have attached one exclusive fence (normally associated with write operations) or N shared fences (read operations). The RCU mechanism is used to protect read access to fences from locked write-side updates.

void **dma_resv_init**(struct dma_resv * obj)
initialize a reservation object

Parameters

struct dma_resv * obj the reservation object

void **dma_resv_fini**(struct dma_resv * obj)
destroys a reservation object

Parameters

struct dma_resv * obj the reservation object

int **dma_resv_reserve_shared**(struct dma_resv * obj, unsigned int num_fences)
Reserve space to add shared fences to a dma_resv.

Parameters

struct dma_resv * obj reservation object

unsigned int num_fences number of fences we want to add

Description

Should be called before `dma_resv_add_shared_fence()`. Must be called with obj->lock held.

RETURNS Zero for success, or -errno

void **dma_resv_add_shared_fence**(struct dma_resv * obj, struct dma_fence * fence)
Add a fence to a shared slot

Parameters

struct dma_resv * obj the reservation object

struct dma_fence * fence the shared fence to add

Description

Add a fence to a shared slot, obj->lock must be held, and `dma_resv_reserve_shared()` has been called.

void **dma_resv_add_excl_fence**(struct dma_resv * obj, struct dma_fence * fence)
Add an exclusive fence.

Parameters

struct dma_resv * obj the reservation object

struct dma_fence * fence the shared fence to add

Description

Add a fence to the exclusive slot. The obj->lock must be held.

int **dma_resv_copy_fences**(struct dma_resv * dst, struct dma_resv * src)
Copy all fences from src to dst.

Parameters

struct dma_resv * dst the destination reservation object

struct dma_resv * src the source reservation object

Description

Copy all fences from src to dst. dst-lock must be held.

int **dma_resv_get_fences_rcu**(struct dma_resv * obj, struct dma_fence ** pfence_excl, unsigned * pshared_count, struct dma_fence *** pshared)
Get an object's shared and exclusive fences without update side lock held

Parameters

struct dma_resv * obj the reservation object

struct dma_fence ** pfence_excl the returned exclusive fence (or NULL)

unsigned * pshared_count the number of shared fences returned

struct dma_fence * pshared** the array of shared fence ptrs returned (array is krealloc'd to the required size, and must be freed by caller)

Description

Retrieve all fences from the reservation object. If the pointer for the exclusive fence is not specified the fence is put into the array of the shared fences as well. Returns either zero or -ENOMEM.

long **dma_resv_wait_timeout_rcu**(struct dma_resv * obj, bool wait_all, bool intr, unsigned long timeout)
Wait on reservation's objects shared and/or exclusive fences.

Parameters

struct dma_resv * obj the reservation object

bool wait_all if true, wait on all fences, else wait on just exclusive fence

bool intr if true, do interruptible wait

unsigned long timeout timeout value in jiffies or zero to return immediately

Description

RETURNS Returns -ERESTARTSYS if interrupted, 0 if the wait timed out, or greater than zer on success.

bool **dma_resv_test_signaled_rcu**(struct dma_resv * obj, bool test_all)
Test if a reservation object's fences have been signaled.

Parameters

struct dma_resv * obj the reservation object

bool test_all if true, test all fences, otherwise only test the exclusive fence

Description

RETURNS true if all fences signaled, else false

struct **dma_resv_list**
a list of shared fences

Definition

```
struct dma_resv_list {
  struct rcu_head rcu;
  u32 shared_count, shared_max;
  struct dma_fence __rcu *shared[];
};
```

Members

rcu for internal use

shared_count table of shared fences

shared_max for growing shared fence table

shared shared fence table

struct **dma_resv**
a reservation object manages fences for a buffer

Definition

```
struct dma_resv {
  struct ww_mutex lock;
  seqcount_t seq;
  struct dma_fence __rcu *fence_excl;
  struct dma_resv_list __rcu *fence;
};
```

Members

lock update side lock

seq sequence count for managing RCU read-side synchronization

fence_excl the exclusive fence, if there is one currently

fence list of current shared fences

struct dma_resv_list * **dma_resv_get_list**(struct dma_resv * obj)
get the reservation object's shared fence list, with update-side lock held

Parameters

struct dma_resv * obj the reservation object

Description

Returns the shared fence list. Does NOT take references to the fence. The obj->lock must be held.

int **dma_resv_lock**(struct dma_resv * obj, struct ww_acquire_ctx * ctx)
lock the reservation object

Parameters

struct dma_resv * obj the reservation object

struct ww_acquire_ctx * ctx the locking context

Description

Locks the reservation object for exclusive access and modification. Note, that the lock is only against other writers, readers will run concurrently with a writer under RCU. The seqlock is used to notify readers if they overlap with a writer.

As the reservation object may be locked by multiple parties in an undefined order, a #ww_acquire_ctx is passed to unwind if a cycle is detected. See ww_mutex_lock() and ww_acquire_init(). A reservation object may be locked by itself by passing NULL as **ctx**.

int **dma_resv_lock_interruptible**(struct dma_resv * obj, struct ww_acquire_ctx * ctx)
lock the reservation object

Parameters

struct dma_resv * obj the reservation object

struct ww_acquire_ctx * ctx the locking context

Description

Locks the reservation object interruptible for exclusive access and modification. Note, that the lock is only against other writers, readers will run concurrently with a writer under RCU. The seqlock is used to notify readers if they overlap with a writer.

As the reservation object may be locked by multiple parties in an undefined order, a #ww_acquire_ctx is passed to unwind if a cycle is detected. See ww_mutex_lock() and ww_acquire_init(). A reservation object may be locked by itself by passing NULL as **ctx**.

void **dma_resv_lock_slow**(struct dma_resv * obj, struct ww_acquire_ctx * ctx)
slowpath lock the reservation object

Parameters

struct dma_resv * obj the reservation object

struct ww_acquire_ctx * ctx the locking context

Description

Acquires the reservation object after a die case. This function will sleep until the lock becomes available. See `dma_resv_lock()` as well.

int **dma_resv_lock_slow_interruptible**(struct dma_resv * obj, struct ww_acquire_ctx * ctx)
slowpath lock the reservation object, interruptible

Parameters

struct dma_resv * obj the reservation object

struct ww_acquire_ctx * ctx the locking context

Description

Acquires the reservation object interruptible after a die case. This function will sleep until the lock becomes available. See `dma_resv_lock_interruptible()` as well.

bool **dma_resv_trylock**(struct dma_resv * obj)
trylock the reservation object

Parameters

struct dma_resv * obj the reservation object

Description

Tries to lock the reservation object for exclusive access and modification. Note, that the lock is only against other writers, readers will run concurrently with a writer under RCU. The seqlock is used to notify readers if they overlap with a writer.

Also note that since no context is provided, no deadlock protection is possible.

Returns true if the lock was acquired, false otherwise.

bool **dma_resv_is_locked**(struct dma_resv * obj)
is the reservation object locked

Parameters

struct dma_resv * obj the reservation object

Description

Returns true if the mutex is locked, false if unlocked.

struct ww_acquire_ctx * **dma_resv_locking_ctx**(struct dma_resv * obj)
returns the context used to lock the object

Parameters

struct dma_resv * obj the reservation object

Description

Returns the context used to lock a reservation object or NULL if no context was used or the object is not locked at all.

void **dma_resv_unlock**(struct dma_resv * obj)
unlock the reservation object

Parameters

struct dma_resv * obj the reservation object

Description

Unlocks the reservation object following exclusive access.

struct dma_fence * **dma_resv_get_excl**(struct dma_resv * obj)
get the reservation object's exclusive fence, with update-side lock held

Parameters

struct dma_resv * obj the reservation object

Description

Returns the exclusive fence (if any). Does NOT take a reference. Writers must hold obj->lock, readers may only hold a RCU read side lock.

RETURNS The exclusive fence or NULL

struct dma_fence * **dma_resv_get_excl_rcu**(struct dma_resv * obj)
get the reservation object's exclusive fence, without lock held.

Parameters

struct dma_resv * obj the reservation object

Description

If there is an exclusive fence, this atomically increments it's reference count and returns it.

RETURNS The exclusive fence or NULL if none

10.3 DMA Fences

DMA fences, represented by `struct dma_fence`, are the kernel internal synchronization primitive for DMA operations like GPU rendering, video encoding/decoding, or displaying buffers on a screen.

A fence is initialized using `dma_fence_init()` and completed using `dma_fence_signal()`. Fences are associated with a context, allocated through `dma_fence_context_alloc()`, and all fences on the same context are fully ordered.

Since the purposes of fences is to facilitate cross-device and cross-application synchronization, there's multiple ways to use one:

- Individual fences can be exposed as a `sync_file`, accessed as a file descriptor from userspace, created by calling `sync_file_create()`. This is called explicit fencing, since userspace passes around explicit synchronization points.
- Some subsystems also have their own explicit fencing primitives, like `drm_syncobj`. Compared to `sync_file`, a `drm_syncobj` allows the underlying fence to be updated.
- Then there's also implicit fencing, where the synchronization points are implicitly passed around as part of shared `dma_buf` instances. Such implicit fences are stored in `struct dma_resv` through the `dma_buf.resv` pointer.

10.3.1 DMA Fences Functions Reference

struct dma_fence * **dma_fence_get_stub**(void)
return a signaled fence

Parameters

void no arguments

Description

Return a stub fence which is already signaled.

u64 **dma_fence_context_alloc**(unsigned num)
allocate an array of fence contexts

Parameters

unsigned num amount of contexts to allocate

Description

This function will return the first index of the number of fence contexts allocated. The fence context is used for setting `dma_fence.context` to a unique number by passing the context to `dma_fence_init()`.

int **dma_fence_signal_locked**(struct dma_fence * fence)
signal completion of a fence

Parameters

struct dma_fence * fence the fence to signal

Description

Signal completion for software callbacks on a fence, this will unblock `dma_fence_wait()` calls and run all the callbacks added with `dma_fence_add_callback()`. Can be called multiple times, but since a fence can only go from the unsignaled to the signaled state and not back, it will only be effective the first time.

Unlike `dma_fence_signal()`, this function must be called with `dma_fence.lock` held.

Returns 0 on success and a negative error value when **fence** has been signalled already.

int **dma_fence_signal**(struct dma_fence * fence)
signal completion of a fence

Parameters

struct dma_fence * fence the fence to signal

Description

Signal completion for software callbacks on a fence, this will unblock `dma_fence_wait()` calls and run all the callbacks added with `dma_fence_add_callback()`. Can be called multiple times, but since a fence can only go from the unsignaled to the signaled state and not back, it will only be effective the first time.

Returns 0 on success and a negative error value when **fence** has been signalled already.

signed long **dma_fence_wait_timeout**(struct dma_fence * fence, bool intr, signed long timeout)
sleep until the fence gets signaled or until timeout elapses

Parameters

struct dma_fence * fence the fence to wait on

bool intr if true, do an interruptible wait

signed long timeout timeout value in jiffies, or MAX_SCHEDULE_TIMEOUT

Description

Returns -ERESTARTSYS if interrupted, 0 if the wait timed out, or the remaining timeout in jiffies on success. Other error values may be returned on custom implementations.

Performs a synchronous wait on this fence. It is assumed the caller directly or indirectly (buf-mgr between reservation and committing) holds a reference to the fence, otherwise the fence might be freed before return, resulting in undefined behavior.

See also `dma_fence_wait()` and `dma_fence_wait_any_timeout()`.

void **dma_fence_release**(struct kref * kref)
default relese function for fences

Parameters

struct kref * kref `dma_fence.recfount`

Description

This is the default release functions for `dma_fence`. Drivers shouldn't call this directly, but instead call `dma_fence_put()`.

void **dma_fence_free**(struct dma_fence * fence)
default release function for `dma_fence`.

Parameters

struct dma_fence * fence fence to release

Description

This is the default implementation for `dma_fence_ops.release`. It calls kfree_rcu() on **fence**.

void **dma_fence_enable_sw_signaling**(struct dma_fence * fence)
enable signaling on fence

Parameters

struct dma_fence * fence the fence to enable

Description

This will request for sw signaling to be enabled, to make the fence complete as soon as possible. This calls `dma_fence_ops.enable_signaling` internally.

int **dma_fence_add_callback**(struct dma_fence * fence, struct dma_fence_cb * cb, dma_fence_func_t func)
add a callback to be called when the fence is signaled

Parameters

struct dma_fence * fence the fence to wait on

struct dma_fence_cb * cb the callback to register

dma_fence_func_t func the function to call

Description

cb will be initialized by `dma_fence_add_callback()`, no initialization by the caller is required. Any number of callbacks can be registered to a fence, but a callback can only be registered to one fence at a time.

Note that the callback can be called from an atomic context. If fence is already signaled, this function will return -ENOENT (and not call the callback).

Add a software callback to the fence. Same restrictions apply to refcount as it does to `dma_fence_wait()`, however the caller doesn't need to keep a refcount to fence afterward `dma_fence_add_callback()` has returned: when software access is enabled, the creator of the fence is required to keep the fence alive until after it signals with `dma_fence_signal()`. The callback itself can be called from irq context.

Returns 0 in case of success, -ENOENT if the fence is already signaled and -EINVAL in case of error.

int **dma_fence_get_status**(struct dma_fence * fence)
returns the status upon completion

Parameters

struct dma_fence * fence the dma_fence to query

Description

This wraps `dma_fence_get_status_locked()` to return the error status condition on a signaled fence. See `dma_fence_get_status_locked()` for more details.

Returns 0 if the fence has not yet been signaled, 1 if the fence has been signaled without an error condition, or a negative error code if the fence has been completed in err.

bool **dma_fence_remove_callback**(struct dma_fence * fence, struct dma_fence_cb * cb)
remove a callback from the signaling list

Parameters

struct dma_fence * fence the fence to wait on

struct dma_fence_cb * cb the callback to remove

Description

Remove a previously queued callback from the fence. This function returns true if the callback is successfully removed, or false if the fence has already been signaled.

WARNING: Cancelling a callback should only be done if you really know what you're doing, since deadlocks and race conditions could occur all too easily. For this reason, it should only ever be done on hardware lockup recovery, with a reference held to the fence.

Behaviour is undefined if **cb** has not been added to **fence** using `dma_fence_add_callback()` beforehand.

signed long **dma_fence_default_wait**(struct dma_fence * fence, bool intr, signed long timeout)
default sleep until the fence gets signaled or until timeout elapses

Parameters

struct dma_fence * fence the fence to wait on

bool intr if true, do an interruptible wait

signed long timeout timeout value in jiffies, or MAX_SCHEDULE_TIMEOUT

Description

Returns -ERESTARTSYS if interrupted, 0 if the wait timed out, or the remaining timeout in jiffies on success. If timeout is zero the value one is returned if the fence is already signaled for consistency with other functions taking a jiffies timeout.

signed long **dma_fence_wait_any_timeout**(struct dma_fence ** fences, uint32_t count, bool intr, signed long timeout, uint32_t * idx)
sleep until any fence gets signaled or until timeout elapses

Parameters

struct dma_fence ** fences array of fences to wait on

uint32_t count number of fences to wait on

bool intr if true, do an interruptible wait

signed long timeout timeout value in jiffies, or MAX_SCHEDULE_TIMEOUT

uint32_t * idx used to store the first signaled fence index, meaningful only on positive return

Description

Returns -EINVAL on custom fence wait implementation, -ERESTARTSYS if interrupted, 0 if the wait timed out, or the remaining timeout in jiffies on success.

Synchronous waits for the first fence in the array to be signaled. The caller needs to hold a reference to all fences in the array, otherwise a fence might be freed before return, resulting in undefined behavior.

See also `dma_fence_wait()` and `dma_fence_wait_timeout()`.

void **dma_fence_init**(struct dma_fence * fence, const struct dma_fence_ops * ops, spinlock_t * lock, u64 context, u64 seqno)
Initialize a custom fence.

Parameters

struct dma_fence * fence the fence to initialize

const struct dma_fence_ops * ops the dma_fence_ops for operations on this fence

spinlock_t * lock the irqsafe spinlock to use for locking this fence

u64 context the execution context this fence is run on

u64 seqno a linear increasing sequence number for this context

Description

Initializes an allocated fence, the caller doesn't have to keep its refcount after committing with this fence, but it will need to hold a refcount again if `dma_fence_ops.enable_signaling` gets called.

context and seqno are used for easy comparison between fences, allowing to check which fence is later by simply using `dma_fence_later()`.

struct **dma_fence**
software synchronization primitive

Definition

```
struct dma_fence {
  spinlock_t *lock;
  const struct dma_fence_ops *ops;
  union {
    struct list_head cb_list;
    ktime_t timestamp;
    struct rcu_head rcu;
  };
  u64 context;
  u64 seqno;
  unsigned long flags;
  struct kref refcount;
  int error;
};
```

Members

lock spin_lock_irqsave used for locking

ops dma_fence_ops associated with this fence

{unnamed_union} anonymous

cb_list list of all callbacks to call

timestamp Timestamp when the fence was signaled.

rcu used for releasing fence with kfree_rcu

context execution context this fence belongs to, returned by `dma_fence_context_alloc()`

seqno the sequence number of this fence inside the execution context, can be compared to decide which fence would be signaled later.

flags A mask of DMA_FENCE_FLAG_* defined below

refcount refcount for this fence

error Optional, only valid if < 0, must be set before calling dma_fence_signal, indicates that the fence has completed with an error.

Description

the flags member must be manipulated and read using the appropriate atomic ops (bit_*), so taking the spinlock will not be needed most of the time.

DMA_FENCE_FLAG_SIGNALED_BIT - fence is already signaled DMA_FENCE_FLAG_TIMESTAMP_BIT - timestamp recorded for fence signaling DMA_FENCE_FLAG_ENABLE_SIGNAL_BIT - enable_signaling might have been called DMA_FENCE_FLAG_USER_BITS - start of the unused bits, can be used by the implementer of the fence for its own purposes. Can be used in different ways by different fence implementers, so do not rely on this.

Since atomic bitops are used, this is not guaranteed to be the case. Particularly, if the bit was set, but dma_fence_signal was called right before this bit was set, it would have been able to set the DMA_FENCE_FLAG_SIGNALED_BIT, before enable_signaling was called. Adding a check for DMA_FENCE_FLAG_SIGNALED_BIT after setting DMA_FENCE_FLAG_ENABLE_SIGNAL_BIT closes this race, and makes sure that after dma_fence_signal was called, any enable_signaling call will have either been completed, or never called at all.

struct **dma_fence_cb**
callback for `dma_fence_add_callback()`

Definition

```
struct dma_fence_cb {
  struct list_head node;
  dma_fence_func_t func;
};
```

Members

node used by `dma_fence_add_callback()` to append this struct to fence::cb_list

func dma_fence_func_t to call

Description

This struct will be initialized by `dma_fence_add_callback()`, additional data can be passed along by embedding dma_fence_cb in another struct.

struct **dma_fence_ops**
operations implemented for fence

Definition

```
struct dma_fence_ops {
  bool use_64bit_seqno;
  const char * (*get_driver_name)(struct dma_fence *fence);
  const char * (*get_timeline_name)(struct dma_fence *fence);
  bool (*enable_signaling)(struct dma_fence *fence);
  bool (*signaled)(struct dma_fence *fence);
  signed long (*wait)(struct dma_fence *fence, bool intr, signed long␣
↪timeout);
```

(continues on next page)

(continued from previous page)

```
  void (*release)(struct dma_fence *fence);
  void (*fence_value_str)(struct dma_fence *fence, char *str, int size);
  void (*timeline_value_str)(struct dma_fence *fence, char *str, int size);
};
```

Members

use_64bit_seqno True if this dma_fence implementation uses 64bit seqno, false otherwise.

get_driver_name Returns the driver name. This is a callback to allow drivers to compute the name at runtime, without having it to store permanently for each fence, or build a cache of some sort.

This callback is mandatory.

get_timeline_name Return the name of the context this fence belongs to. This is a callback to allow drivers to compute the name at runtime, without having it to store permanently for each fence, or build a cache of some sort.

This callback is mandatory.

enable_signaling Enable software signaling of fence.

For fence implementations that have the capability for hw->hw signaling, they can implement this op to enable the necessary interrupts, or insert commands into cmdstream, etc, to avoid these costly operations for the common case where only hw->hw synchronization is required. This is called in the first `dma_fence_wait()` or `dma_fence_add_callback()` path to let the fence implementation know that there is another driver waiting on the signal (ie. hw->sw case).

This function can be called from atomic context, but not from irq context, so normal spinlocks can be used.

A return value of false indicates the fence already passed, or some failure occurred that made it impossible to enable signaling. True indicates successful enabling.

`dma_fence.error` may be set in enable_signaling, but only when false is returned.

Since many implementations can call `dma_fence_signal()` even when before **enable_signaling** has been called there' s a race window, where the `dma_fence_signal()` might result in the final fence reference being released and its memory freed. To avoid this, implementations of this callback should grab their own reference using `dma_fence_get()`, to be released when the fence is signalled (through e.g. the interrupt handler).

This callback is optional. If this callback is not present, then the driver must always have signaling enabled.

signaled Peek whether the fence is signaled, as a fastpath optimization for e.g. `dma_fence_wait()` or `dma_fence_add_callback()`. Note that this callback does not need to make any guarantees beyond that a fence once indicates as signalled must always return true from this callback. This callback may return false even if the fence has completed already, in this

case information hasn’ t propogated throug the system yet. See also `dma_fence_is_signaled()`.

May set `dma_fence.error` if returning true.

This callback is optional.

wait Custom wait implementation, defaults to `dma_fence_default_wait()` if not set.

The dma_fence_default_wait implementation should work for any fence, as long as **enable_signaling** works correctly. This hook allows drivers to have an optimized version for the case where a process context is already available, e.g. if **enable_signaling** for the general case needs to set up a worker thread.

Must return -ERESTARTSYS if the wait is intr = true and the wait was interrupted, and remaining jiffies if fence has signaled, or 0 if wait timed out. Can also return other error values on custom implementations, which should be treated as if the fence is signaled. For example a hardware lockup could be reported like that.

This callback is optional.

release Called on destruction of fence to release additional resources. Can be called from irq context. This callback is optional. If it is NULL, then `dma_fence_free()` is instead called as the default implementation.

fence_value_str Callback to fill in free-form debug info specific to this fence, like the sequence number.

This callback is optional.

timeline_value_str Fills in the current value of the timeline as a string, like the sequence number. Note that the specific fence passed to this function should not matter, drivers should only use it to look up the corresponding timeline structures.

void **dma_fence_put**(struct dma_fence * fence)
decreases refcount of the fence

Parameters

struct dma_fence * fence fence to reduce refcount of

struct dma_fence * **dma_fence_get**(struct dma_fence * fence)
increases refcount of the fence

Parameters

struct dma_fence * fence fence to increase refcount of

Description

Returns the same fence, with refcount increased by 1.

struct dma_fence * **dma_fence_get_rcu**(struct dma_fence * fence)
get a fence from a dma_resv_list with rcu read lock

Parameters

struct dma_fence * fence fence to increase refcount of

Description

Function returns NULL if no refcount could be obtained, or the fence.

struct dma_fence * **dma_fence_get_rcu_safe**(struct dma_fence __rcu ** fencep)
acquire a reference to an RCU tracked fence

Parameters

struct dma_fence __rcu ** fencep pointer to fence to increase refcount of

Description

Function returns NULL if no refcount could be obtained, or the fence. This function handles acquiring a reference to a fence that may be reallocated within the RCU grace period (such as with SLAB_TYPESAFE_BY_RCU), so long as the caller is using RCU on the pointer to the fence.

An alternative mechanism is to employ a seqlock to protect a bunch of fences, such as used by struct dma_resv. When using a seqlock, the seqlock must be taken before and checked after a reference to the fence is acquired (as shown here).

The caller is required to hold the RCU read lock.

bool **dma_fence_is_signaled_locked**(struct dma_fence * fence)
Return an indication if the fence is signaled yet.

Parameters

struct dma_fence * fence the fence to check

Description

Returns true if the fence was already signaled, false if not. Since this function doesn't enable signaling, it is not guaranteed to ever return true if `dma_fence_add_callback()`, `dma_fence_wait()` or `dma_fence_enable_sw_signaling()` haven't been called before.

This function requires `dma_fence.lock` to be held.

See also `dma_fence_is_signaled()`.

bool **dma_fence_is_signaled**(struct dma_fence * fence)
Return an indication if the fence is signaled yet.

Parameters

struct dma_fence * fence the fence to check

Description

Returns true if the fence was already signaled, false if not. Since this function doesn't enable signaling, it is not guaranteed to ever return true if `dma_fence_add_callback()`, `dma_fence_wait()` or `dma_fence_enable_sw_signaling()` haven't been called before.

It's recommended for seqno fences to call dma_fence_signal when the operation is complete, it makes it possible to prevent issues from wraparound between time of issue and time of use by checking the return value of this function before calling hardware-specific wait instructions.

See also `dma_fence_is_signaled_locked()`.

bool **__dma_fence_is_later**(u64 f1, u64 f2, const struct dma_fence_ops * ops)
return if f1 is chronologically later than f2

Parameters

u64 f1 the first fence's seqno

u64 f2 the second fence's seqno from the same context

const struct dma_fence_ops * ops dma_fence_ops associated with the seqno

Description

Returns true if f1 is chronologically later than f2. Both fences must be from the same context, since a seqno is not common across contexts.

bool **dma_fence_is_later**(struct dma_fence * f1, struct dma_fence * f2)
return if f1 is chronologically later than f2

Parameters

struct dma_fence * f1 the first fence from the same context

struct dma_fence * f2 the second fence from the same context

Description

Returns true if f1 is chronologically later than f2. Both fences must be from the same context, since a seqno is not re-used across contexts.

struct dma_fence * **dma_fence_later**(struct dma_fence * f1, struct dma_fence * f2)
return the chronologically later fence

Parameters

struct dma_fence * f1 the first fence from the same context

struct dma_fence * f2 the second fence from the same context

Description

Returns NULL if both fences are signaled, otherwise the fence that would be signaled last. Both fences must be from the same context, since a seqno is not re-used across contexts.

int **dma_fence_get_status_locked**(struct dma_fence * fence)
returns the status upon completion

Parameters

struct dma_fence * fence the dma_fence to query

Description

Drivers can supply an optional error status condition before they signal the fence (to indicate whether the fence was completed due to an error rather than success). The value of the status condition is only valid if the fence has been signaled, `dma_fence_get_status_locked()` first checks the signal state before reporting the error status.

Returns 0 if the fence has not yet been signaled, 1 if the fence has been signaled without an error condition, or a negative error code if the fence has been completed in err.

void **dma_fence_set_error**(struct dma_fence * fence, int error)
flag an error condition on the fence

Parameters

struct dma_fence * fence the dma_fence

int error the error to store

Description

Drivers can supply an optional error status condition before they signal the fence, to indicate that the fence was completed due to an error rather than success. This must be set before signaling (so that the value is visible before any waiters on the signal callback are woken). This helper exists to help catching erroneous setting of #dma_fence.error.

signed long **dma_fence_wait**(struct dma_fence * fence, bool intr)
sleep until the fence gets signaled

Parameters

struct dma_fence * fence the fence to wait on

bool intr if true, do an interruptible wait

Description

This function will return -ERESTARTSYS if interrupted by a signal, or 0 if the fence was signaled. Other error values may be returned on custom implementations.

Performs a synchronous wait on this fence. It is assumed the caller directly or indirectly holds a reference to the fence, otherwise the fence might be freed before return, resulting in undefined behavior.

See also `dma_fence_wait_timeout()` and `dma_fence_wait_any_timeout()`.

10.3.2 Seqno Hardware Fences

struct seqno_fence * **to_seqno_fence**(struct dma_fence * fence)
cast a fence to a seqno_fence

Parameters

struct dma_fence * fence fence to cast to a seqno_fence

Description

Returns NULL if the fence is not a seqno_fence, or the seqno_fence otherwise.

void **seqno_fence_init**(struct seqno_fence * fence, spinlock_t * lock, struct dma_buf * sync_buf, uint32_t context, uint32_t seqno_ofs, uint32_t seqno, enum seqno_fence_condition cond, const struct dma_fence_ops * ops)
initialize a seqno fence

Parameters

struct seqno_fence * fence seqno_fence to initialize

spinlock_t * lock pointer to spinlock to use for fence

struct dma_buf * sync_buf buffer containing the memory location to signal on

uint32_t context the execution context this fence is a part of

uint32_t seqno_ofs the offset within **sync_buf**

uint32_t seqno the sequence # to signal on

enum seqno_fence_condition cond fence wait condition

const struct dma_fence_ops * ops the fence_ops for operations on this seqno fence

Description

This function initializes a struct seqno_fence with passed parameters, and takes a reference on sync_buf which is released on fence destruction.

A seqno_fence is a dma_fence which can complete in software when enable_signaling is called, but it also completes when (s32)((sync_buf)[seqno_ofs] - seqno) >= 0 is true

The seqno_fence will take a refcount on the sync_buf until it's destroyed, but actual lifetime of sync_buf may be longer if one of the callers take a reference to it.

Certain hardware have instructions to insert this type of wait condition in the command stream, so no intervention from software would be needed. This type of fence can be destroyed before completed, however a reference on the sync_buf dma-buf can be taken. It is encouraged to re-use the same dma-buf for sync_buf, since mapping or unmapping the sync_buf to the device's vm can be expensive.

It is recommended for creators of seqno_fence to call `dma_fence_signal()` before destruction. This will prevent possible issues from wraparound at time of issue vs time of check, since users can check `dma_fence_is_signaled()` before submitting instructions for the hardware to wait on the fence. However, when ops.enable_signaling is not called, it doesn't have to be done as soon as possible, just before there's any real danger of seqno wraparound.

10.3.3 DMA Fence Array

struct dma_fence_array * **dma_fence_array_create**(int num_fences, struct dma_fence ** fences, u64 context, unsigned seqno, bool signal_on_any)

Create a custom fence array

Parameters

int num_fences [in] number of fences to add in the array

struct dma_fence ** fences [in] array containing the fences

u64 context [in] fence context to use

unsigned seqno [in] sequence number to use

bool signal_on_any [in] signal on any fence in the array

Description

Allocate a dma_fence_array object and initialize the base fence with `dma_fence_init()`. In case of error it returns NULL.

The caller should allocate the fences array with num_fences size and fill it with the fences it wants to add to the object. Ownership of this array is taken and `dma_fence_put()` is used on each fence on release.

If **signal_on_any** is true the fence array signals if any fence in the array signals, otherwise it signals when all fences in the array signal.

bool **dma_fence_match_context**(struct dma_fence * fence, u64 context)
Check if all fences are from the given context

Parameters

struct dma_fence * fence [in] fence or fence array

u64 context [in] fence context to check all fences against

Description

Checks the provided fence or, for a fence array, all fences in the array against the given context. Returns false if any fence is from a different context.

struct **dma_fence_array_cb**
callback helper for fence array

Definition

```
struct dma_fence_array_cb {
  struct dma_fence_cb cb;
  struct dma_fence_array *array;
};
```

Members

cb fence callback structure for signaling

array reference to the parent fence array object

struct **dma_fence_array**
fence to represent an array of fences

Definition

```
struct dma_fence_array {
  struct dma_fence base;
  spinlock_t lock;
  unsigned num_fences;
  atomic_t num_pending;
  struct dma_fence **fences;
  struct irq_work work;
};
```

Members

base fence base class

lock spinlock for fence handling

num_fences number of fences in the array

num_pending fences in the array still pending

fences array of the fences

work internal irq_work function

bool **dma_fence_is_array**(struct dma_fence * fence)
check if a fence is from the array subsclass

Parameters

struct dma_fence * fence fence to test

Description

Return true if it is a dma_fence_array and false otherwise.

struct dma_fence_array * **to_dma_fence_array**(struct dma_fence * fence)
cast a fence to a dma_fence_array

Parameters

struct dma_fence * fence fence to cast to a dma_fence_array

Description

Returns NULL if the fence is not a dma_fence_array, or the dma_fence_array otherwise.

10.3.4 DMA Fence uABI/Sync File

struct sync_file * **sync_file_create**(struct dma_fence * fence)
creates a sync file

Parameters

struct dma_fence * fence fence to add to the sync_fence

Description

Creates a sync_file containg **fence**. This function acquires and additional reference of **fence** for the newly-created `sync_file`, if it succeeds. The sync_file can be released with fput(sync_file->file). Returns the sync_file or NULL in case of error.

struct dma_fence * **sync_file_get_fence**(int fd)
get the fence related to the sync_file fd

Parameters

int fd sync_file fd to get the fence from

Description

Ensures **fd** references a valid sync_file and returns a fence that represents all fence in the sync_file. On error NULL is returned.

struct **sync_file**
sync file to export to the userspace

Definition

```
struct sync_file {
  struct file             *file;
  char user_name[32];
#ifdef CONFIG_DEBUG_FS;
  struct list_head        sync_file_list;
#endif;
  wait_queue_head_t wq;
  unsigned long           flags;
  struct dma_fence        *fence;
  struct dma_fence_cb cb;
};
```

Members

CHAPTER

ELEVEN

DEVICE LINKS

By default, the driver core only enforces dependencies between devices that are borne out of a parent/child relationship within the device hierarchy: When suspending, resuming or shutting down the system, devices are ordered based on this relationship, i.e. children are always suspended before their parent, and the parent is always resumed before its children.

Sometimes there is a need to represent device dependencies beyond the mere parent/child relationship, e.g. between siblings, and have the driver core automatically take care of them.

Secondly, the driver core by default does not enforce any driver presence dependencies, i.e. that one device must be bound to a driver before another one can probe or function correctly.

Often these two dependency types come together, so a device depends on another one both with regards to driver presence and with regards to suspend/resume and shutdown ordering.

Device links allow representation of such dependencies in the driver core.

In its standard or managed form, a device link combines both dependency types: It guarantees correct suspend/resume and shutdown ordering between a "supplier" device and its "consumer" devices, and it guarantees driver presence on the supplier. The consumer devices are not probed before the supplier is bound to a driver, and they're unbound before the supplier is unbound.

When driver presence on the supplier is irrelevant and only correct suspend/resume and shutdown ordering is needed, the device link may simply be set up with the `DL_FLAG_STATELESS` flag. In other words, enforcing driver presence on the supplier is optional.

Another optional feature is runtime PM integration: By setting the `DL_FLAG_PM_RUNTIME` flag on addition of the device link, the PM core is instructed to runtime resume the supplier and keep it active whenever and for as long as the consumer is runtime resumed.

11.1 Usage

The earliest point in time when device links can be added is after `device_add()` has been called for the supplier and `device_initialize()` has been called for the consumer.

It is legal to add them later, but care must be taken that the system remains in a consistent state: E.g. a device link cannot be added in the midst of a suspend/resume transition, so either commencement of such a transition needs to be prevented with `lock_system_sleep()`, or the device link needs to be added from a function which is guaranteed not to run in parallel to a suspend/resume transition, such as from a device `->probe` callback or a boot-time PCI quirk.

Another example for an inconsistent state would be a device link that represents a driver presence dependency, yet is added from the consumer's `->probe` callback while the supplier hasn't started to probe yet: Had the driver core known about the device link earlier, it wouldn't have probed the consumer in the first place. The onus is thus on the consumer to check presence of the supplier after adding the link, and defer probing on non-presence. [Note that it is valid to create a link from the consumer's `->probe` callback while the supplier is still probing, but the consumer must know that the supplier is functional already at the link creation time (that is the case, for instance, if the consumer has just acquired some resources that would not have been available had the supplier not been functional then).]

If a device link with `DL_FLAG_STATELESS` set (i.e. a stateless device link) is added in the `->probe` callback of the supplier or consumer driver, it is typically deleted in its `->remove` callback for symmetry. That way, if the driver is compiled as a module, the device link is added on module load and orderly deleted on unload. The same restrictions that apply to device link addition (e.g. exclusion of a parallel suspend/resume transition) apply equally to deletion. Device links managed by the driver core are deleted automatically by it.

Several flags may be specified on device link addition, two of which have already been mentioned above: `DL_FLAG_STATELESS` to express that no driver presence dependency is needed (but only correct suspend/resume and shutdown ordering) and `DL_FLAG_PM_RUNTIME` to express that runtime PM integration is desired.

Two other flags are specifically targeted at use cases where the device link is added from the consumer's `->probe` callback: `DL_FLAG_RPM_ACTIVE` can be specified to runtime resume the supplier and prevent it from suspending before the consumer is runtime suspended. `DL_FLAG_AUTOREMOVE_CONSUMER` causes the device link to be automatically purged when the consumer fails to probe or later unbinds.

Similarly, when the device link is added from supplier's `->probe` callback, `DL_FLAG_AUTOREMOVE_SUPPLIER` causes the device link to be automatically purged when the supplier fails to probe or later unbinds.

If neither `DL_FLAG_AUTOREMOVE_CONSUMER` nor `DL_FLAG_AUTOREMOVE_SUPPLIER` is set, `DL_FLAG_AUTOPROBE_CONSUMER` can be used to request the driver core to probe for a driver for the consumer driver on the link automatically after a driver has been bound to the supplier device.

Note, however, that any combinations of `DL_FLAG_AUTOREMOVE_CONSUMER`, `DL_FLAG_AUTOREMOVE_SUPPLIER` or `DL_FLAG_AUTOPROBE_CONSUMER` with

DL_FLAG_STATELESS are invalid and cannot be used.

11.2 Limitations

Driver authors should be aware that a driver presence dependency for managed device links (i.e. when DL_FLAG_STATELESS is not specified on link addition) may cause probing of the consumer to be deferred indefinitely. This can become a problem if the consumer is required to probe before a certain initcall level is reached. Worse, if the supplier driver is blacklisted or missing, the consumer will never be probed.

Moreover, managed device links cannot be deleted directly. They are deleted by the driver core when they are not necessary any more in accordance with the DL_FLAG_AUTOREMOVE_CONSUMER and DL_FLAG_AUTOREMOVE_SUPPLIER flags. However, stateless device links (i.e. device links with DL_FLAG_STATELESS set) are expected to be removed by whoever called device_link_add() to add them with the help of either device_link_del() or device_link_remove().

Passing DL_FLAG_RPM_ACTIVE along with DL_FLAG_STATELESS to device_link_add() may cause the PM-runtime usage counter of the supplier device to remain nonzero after a subsequent invocation of either device_link_del() or device_link_remove() to remove the device link returned by it. This happens if device_link_add() is called twice in a row for the same consumer-supplier pair without removing the link between these calls, in which case allowing the PM-runtime usage counter of the supplier to drop on an attempt to remove the link may cause it to be suspended while the consumer is still PM-runtime-active and that has to be avoided. [To work around this limitation it is sufficient to let the consumer runtime suspend at least once, or call pm_runtime_set_suspended() for it with PM-runtime disabled, between the device_link_add() and device_link_del() or device_link_remove() calls.]

Sometimes drivers depend on optional resources. They are able to operate in a degraded mode (reduced feature set or performance) when those resources are not present. An example is an SPI controller that can use a DMA engine or work in PIO mode. The controller can determine presence of the optional resources at probe time but on non-presence there is no way to know whether they will become available in the near future (due to a supplier driver probing) or never. Consequently it cannot be determined whether to defer probing or not. It would be possible to notify drivers when optional resources become available after probing, but it would come at a high cost for drivers as switching between modes of operation at runtime based on the availability of such resources would be much more complex than a mechanism based on probe deferral. In any case optional resources are beyond the scope of device links.

11.3 Examples

- An MMU device exists alongside a busmaster device, both are in the same power domain. The MMU implements DMA address translation for the busmaster device and shall be runtime resumed and kept active whenever and as long as the busmaster device is active. The busmaster device's driver shall not bind before the MMU is bound. To achieve this, a device link with runtime PM integration is added from the busmaster device (consumer) to the MMU device (supplier). The effect with regards to runtime PM is the same as if the MMU was the parent of the master device.

  The fact that both devices share the same power domain would normally suggest usage of a `struct dev_pm_domain` or `struct generic_pm_domain`, however these are not independent devices that happen to share a power switch, but rather the MMU device serves the busmaster device and is useless without it. A device link creates a synthetic hierarchical relationship between the devices and is thus more apt.

- A Thunderbolt host controller comprises a number of PCIe hotplug ports and an NHI device to manage the PCIe switch. On resume from system sleep, the NHI device needs to re-establish PCI tunnels to attached devices before the hotplug ports can resume. If the hotplug ports were children of the NHI, this resume order would automatically be enforced by the PM core, but unfortunately they're aunts. The solution is to add device links from the hotplug ports (consumers) to the NHI device (supplier). A driver presence dependency is not necessary for this use case.

- Discrete GPUs in hybrid graphics laptops often feature an HDA controller for HDMI/DP audio. In the device hierarchy the HDA controller is a sibling of the VGA device, yet both share the same power domain and the HDA controller is only ever needed when an HDMI/DP display is attached to the VGA device. A device link from the HDA controller (consumer) to the VGA device (supplier) aptly represents this relationship.

- ACPI allows definition of a device start order by way of _DEP objects. A classical example is when ACPI power management methods on one device are implemented in terms of I^2C accesses and require a specific I^2C controller to be present and functional for the power management of the device in question to work.

- In some SoCs a functional dependency exists from display, video codec and video processing IP cores on transparent memory access IP cores that handle burst access and compression/decompression.

11.4 Alternatives

- A `struct dev_pm_domain` can be used to override the bus, class or device type callbacks. It is intended for devices sharing a single on/off switch, however it does not guarantee a specific suspend/resume ordering, this needs to be implemented separately. It also does not by itself track the runtime PM status of the involved devices and turn off the power switch only when all of them are runtime suspended. Furthermore it cannot be used to enforce a specific shutdown ordering or a driver presence dependency.
- A `struct generic_pm_domain` is a lot more heavyweight than a device link and does not allow for shutdown ordering or driver presence dependencies. It also cannot be used on ACPI systems.

11.5 Implementation

The device hierarchy, which – as the name implies – is a tree, becomes a directed acyclic graph once device links are added.

Ordering of these devices during suspend/resume is determined by the dpm_list. During shutdown it is determined by the devices_kset. With no device links present, the two lists are a flattened, one-dimensional representations of the device tree such that a device is placed behind all its ancestors. That is achieved by traversing the ACPI namespace or OpenFirmware device tree top-down and appending devices to the lists as they are discovered.

Once device links are added, the lists need to satisfy the additional constraint that a device is placed behind all its suppliers, recursively. To ensure this, upon addition of the device link the consumer and the entire sub-graph below it (all children and consumers of the consumer) are moved to the end of the list. (Call to `device_reorder_to_tail()` from `device_link_add()`.)

To prevent introduction of dependency loops into the graph, it is verified upon device link addition that the supplier is not dependent on the consumer or any children or consumers of the consumer. (Call to `device_is_dependent()` from `device_link_add()`.) If that constraint is violated, `device_link_add()` will return `NULL` and a `WARNING` will be logged.

Notably this also prevents the addition of a device link from a parent device to a child. However the converse is allowed, i.e. a device link from a child to a parent. Since the driver core already guarantees correct suspend/resume and shutdown ordering between parent and child, such a device link only makes sense if a driver presence dependency is needed on top of that. In this case driver authors should weigh carefully if a device link is at all the right tool for the purpose. A more suitable approach might be to simply use deferred probing or add a device flag causing the parent driver to be probed before the child one.

11.6 State machine

enum **device_link_state**
Device link states.

Constants

DL_STATE_NONE The presence of the drivers is not being tracked.

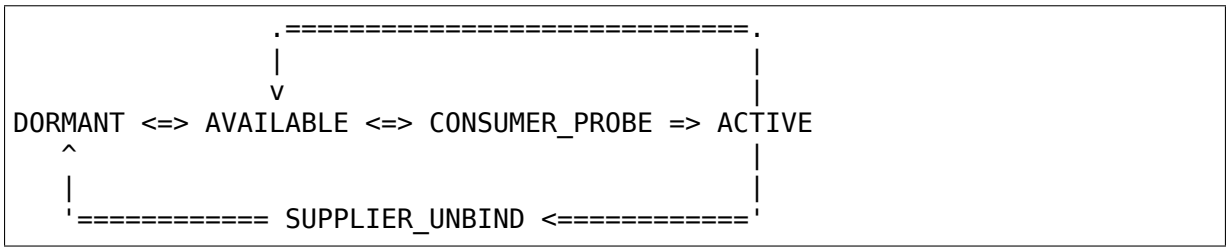
DL_STATE_DORMANT None of the supplier/consumer drivers is present.

DL_STATE_AVAILABLE The supplier driver is present, but the consumer is not.

DL_STATE_CONSUMER_PROBE The consumer is probing (supplier driver present).

DL_STATE_ACTIVE Both the supplier and consumer drivers are present.

DL_STATE_SUPPLIER_UNBIND The supplier driver is unbinding.



- The initial state of a device link is automatically determined by `device_link_add()` based on the driver presence on the supplier and consumer. If the link is created before any devices are probed, it is set to `DL_STATE_DORMANT`.
- When a supplier device is bound to a driver, links to its consumers progress to `DL_STATE_AVAILABLE`. (Call to `device_links_driver_bound()` from `driver_bound()`.)
- Before a consumer device is probed, presence of supplier drivers is verified by checking the consumer device is not in the wait_for_suppliers list and by checking that links to suppliers are in `DL_STATE_AVAILABLE` state. The state of the links is updated to `DL_STATE_CONSUMER_PROBE`. (Call to `device_links_check_suppliers()` from `really_probe()`.) This prevents the supplier from unbinding. (Call to `wait_for_device_probe()` from `device_links_unbind_consumers()`.)
- If the probe fails, links to suppliers revert back to `DL_STATE_AVAILABLE`. (Call to `device_links_no_driver()` from `really_probe()`.)
- If the probe succeeds, links to suppliers progress to `DL_STATE_ACTIVE`. (Call to `device_links_driver_bound()` from `driver_bound()`.)
- When the consumer's driver is later on removed, links to suppliers revert back to `DL_STATE_AVAILABLE`. (Call to `__device_links_no_driver()` from `device_links_driver_cleanup()`, which in turn is called from `__device_release_driver()`.)
- Before a supplier's driver is removed, links to consumers that are not bound to a driver are updated to `DL_STATE_SUPPLIER_UNBIND`. (Call to `device_links_busy()` from `__device_release_driver()`.) This prevents

the consumers from binding. (Call to `device_links_check_suppliers()` from `really_probe()`.) Consumers that are bound are freed from their driver; consumers that are probing are waited for until they are done. (Call to `device_links_unbind_consumers()` from `__device_release_driver()`.) Once all links to consumers are in `DL_STATE_SUPPLIER_UNBIND` state, the supplier driver is released and the links revert to `DL_STATE_DORMANT`. (Call to `device_links_driver_cleanup()` from `__device_release_driver()`.)

11.7 API

struct device_link * **device_link_add**(struct device * consumer, struct device * supplier, u32 flags)

Create a link between two devices.

Parameters

struct device * consumer Consumer end of the link.

struct device * supplier Supplier end of the link.

u32 flags Link flags.

Description

The caller is responsible for the proper synchronization of the link creation with runtime PM. First, setting the DL_FLAG_PM_RUNTIME flag will cause the runtime PM framework to take the link into account. Second, if the DL_FLAG_RPM_ACTIVE flag is set in addition to it, the supplier devices will be forced into the active metastate and reference-counted upon the creation of the link. If DL_FLAG_PM_RUNTIME is not set, DL_FLAG_RPM_ACTIVE will be ignored.

If DL_FLAG_STATELESS is set in **flags**, the caller of this function is expected to release the link returned by it directly with the help of either `device_link_del()` or `device_link_remove()`.

If that flag is not set, however, the caller of this function is handing the management of the link over to the driver core entirely and its return value can only be used to check whether or not the link is present. In that case, the DL_FLAG_AUTOREMOVE_CONSUMER and DL_FLAG_AUTOREMOVE_SUPPLIER device link flags can be used to indicate to the driver core when the link can be safely deleted. Namely, setting one of them in **flags** indicates to the driver core that the link is not going to be used (by the given caller of this function) after unbinding the consumer or supplier driver, respectively, from its device, so the link can be deleted at that point. If none of them is set, the link will be maintained until one of the devices pointed to by it (either the consumer or the supplier) is unregistered.

Also, if DL_FLAG_STATELESS, DL_FLAG_AUTOREMOVE_CONSUMER and DL_FLAG_AUTOREMOVE_SUPPLIER are not set in **flags** (that is, a persistent managed device link is being added), the DL_FLAG_AUTOPROBE_CONSUMER flag can be used to request the driver core to automaticall probe for a consmer driver after successfully binding a driver to the supplier device.

The combination of DL_FLAG_STATELESS and one of DL_FLAG_AUTOREMOVE_CONSUMER, DL_FLAG_AUTOREMOVE_SUPPLIER, or DL_FLAG_AUTOPROBE_CONSUMER set in **flags** at the same time is invalid and will cause NULL to be returned upfront. However, if a device link between the given **consumer** and **supplier** pair exists already when this function is called for them, the existing link will be returned regardless of its current type and status (the link's flags may be modified then). The caller of this function is then expected to treat the link as though it has just been created, so (in particular) if DL_FLAG_STATELESS was passed in **flags**, the link needs to be released explicitly when not needed any more (as stated above).

A side effect of the link creation is re-ordering of dpm_list and the devices_kset list by moving the consumer device and all devices depending on it to the ends of these lists (that does not happen to devices that have not been registered when this function is called).

The supplier device is required to be registered when this function is called and NULL will be returned if that is not the case. The consumer device need not be registered, however.

void **device_link_del**(struct device_link * link)
Delete a stateless link between two devices.

Parameters

struct device_link * link Device link to delete.

Description

The caller must ensure proper synchronization of this function with runtime PM. If the link was added multiple times, it needs to be deleted as often. Care is required for hotplugged devices: Their links are purged on removal and calling `device_link_del()` is then no longer allowed.

void **device_link_remove**(void * consumer, struct device * supplier)
Delete a stateless link between two devices.

Parameters

void * consumer Consumer end of the link.

struct device * supplier Supplier end of the link.

Description

The caller must ensure proper synchronization of this function with runtime PM.

CHAPTER

TWELVE

COMPONENT HELPER FOR AGGREGATE DRIVERS

The component helper allows drivers to collect a pile of sub-devices, including their bound drivers, into an aggregate driver. Various subsystems already provide functions to get hold of such components, e.g. of_clk_get_by_name(). The component helper can be used when such a subsystem-specific way to find a device is not available: The component helper fills the niche of aggregate drivers for specific hardware, where further standardization into a subsystem would not be practical. The common example is when a logical device (e.g. a DRM display driver) is spread around the SoC on various components (scanout engines, blending blocks, transcoders for various outputs and so on).

The component helper also doesn't solve runtime dependencies, e.g. for system suspend and resume operations. See also device links.

Components are registered using `component_add()` and unregistered with `component_del()`, usually from the driver's probe and disconnect functions.

Aggregate drivers first assemble a component match list of what they need using `component_match_add()`. This is then registered as an aggregate driver using `component_master_add_with_match()`, and unregistered using `component_master_del()`.

12.1 API

struct **component_ops**
callbacks for component drivers

Definition

```
struct component_ops {
  int (*bind)(struct device *comp, struct device *master, void *master_
↪data);
  void (*unbind)(struct device *comp, struct device *master, void *master_
↪data);
};
```

Members

bind Called through `component_bind_all()` when the aggregate driver is ready to bind the overall driver.

unbind Called through `component_unbind_all()` when the aggregate driver is ready to bind the overall driver, or when `component_bind_all()` fails part-ways through and needs to unbind some already bound components.

Description

Components are registered with `component_add()` and unregistered with `component_del()`.

struct **component_master_ops**
callback for the aggregate driver

Definition

```
struct component_master_ops {
  int (*bind)(struct device *master);
  void (*unbind)(struct device *master);
};
```

Members

bind Called when all components or the aggregate driver, as specified in the match list passed to `component_master_add_with_match()`, are ready. Usually there are 3 steps to bind an aggregate driver:

1. Allocate a structure for the aggregate driver.
2. Bind all components to the aggregate driver by calling `component_bind_all()` with the aggregate driver structure as opaque pointer data.
3. Register the aggregate driver with the subsystem to publish its interfaces.

Note that the lifetime of the aggregate driver does not align with any of the underlying `struct device` instances. Therefore devm cannot be used and all resources acquired or allocated in this callback must be explicitly released in the **unbind** callback.

unbind Called when either the aggregate driver, using `component_master_del()`, or one of its components, using `component_del()`, is unregistered.

Description

Aggregate drivers are registered with `component_master_add_with_match()` and unregistered with `component_master_del()`.

void **component_match_add**(struct device * master, struct component_match ** matchptr, int (*compare)(struct device *, void *), void * compare_data)
add a component match entry

Parameters

struct device * master device with the aggregate driver

struct component_match ** matchptr pointer to the list of component matches

int (*)(struct device *, void *) compare compare function to match against all components

void * compare_data opaque pointer passed to the **compare** function

Description

Adds a new component match to the list stored in **matchptr**, which the **master** aggregate driver needs to function. The list of component matches pointed to by **matchptr** must be initialized to NULL before adding the first match. This only matches against components added with `component_add()`.

The allocated match list in **matchptr** is automatically released using devm actions.

See also `component_match_add_release()` and `component_match_add_typed()`.

void **component_match_add_release**(struct device * master, struct component_match ** matchptr, void (*release)(struct device *, void *), int (*compare) (struct device *, void *), void * compare_data)

add a component match entry with release callback

Parameters

struct device * master device with the aggregate driver

struct component_match ** matchptr pointer to the list of component matches

void (*)(struct device *, void *) release release function for **compare_data**

int (*)(struct device *, void *) compare compare function to match against all components

void * compare_data opaque pointer passed to the **compare** function

Description

Adds a new component match to the list stored in **matchptr**, which the **master** aggregate driver needs to function. The list of component matches pointed to by **matchptr** must be initialized to NULL before adding the first match. This only matches against components added with `component_add()`.

The allocated match list in **matchptr** is automatically released using devm actions, where upon **release** will be called to free any references held by **compare_data**, e.g. when **compare_data** is a `device_node` that must be released with of_node_put().

See also `component_match_add()` and `component_match_add_typed()`.

void **component_match_add_typed**(struct device * master, struct component_match ** matchptr, int (*compare_typed)(struct device *, int, void *), void * compare_data)

add a component match entry for a typed component

Parameters

struct device * master device with the aggregate driver

struct component_match ** matchptr pointer to the list of component matches

int (*)(struct device *, int, void *) compare_typed compare function to match against all typed components

void * compare_data opaque pointer passed to the **compare** function

Description

Adds a new component match to the list stored in **matchptr**, which the **master** aggregate driver needs to function. The list of component matches pointed to by **matchptr** must be initialized to NULL before adding the first match. This only matches against components added with `component_add_typed()`.

The allocated match list in **matchptr** is automatically released using devm actions.

See also `component_match_add_release()` and `component_match_add_typed()`.

int **component_master_add_with_match**(struct device * dev, const struct component_master_ops * ops, struct component_match * match)
register an aggregate driver

Parameters

struct device * dev device with the aggregate driver

const struct component_master_ops * ops callbacks for the aggregate driver

struct component_match * match component match list for the aggregate driver

Description

Registers a new aggregate driver consisting of the components added to **match** by calling one of the `component_match_add()` functions. Once all components in **match** are available, it will be assembled by calling `component_master_ops.bind` from **ops**. Must be unregistered by calling `component_master_del()`.

void **component_master_del**(struct device * dev, const struct component_master_ops * ops)
unregister an aggregate driver

Parameters

struct device * dev device with the aggregate driver

const struct component_master_ops * ops callbacks for the aggregate driver

Description

Unregisters an aggregate driver registered with `component_master_add_with_match()`. If necessary the aggregate driver is first disassembled by calling `component_master_ops.unbind` from **ops**.

void **component_unbind_all**(struct device * master_dev, void * data)
unbind all components of an aggregate driver

Parameters

struct device * master_dev device with the aggregate driver

void * data opaque pointer, passed to all components

Description

Unbinds all components of the aggregate **dev** by passing **data** to their `component_ops.unbind` functions. Should be called from `component_master_ops.unbind`.

int **component_bind_all**(struct device * master_dev, void * data)
bind all components of an aggregate driver

Parameters

struct device * master_dev device with the aggregate driver

void * data opaque pointer, passed to all components

Description

Binds all components of the aggregate **dev** by passing **data** to their `component_ops.bind` functions. Should be called from `component_master_ops.bind`.

int **component_add_typed**(struct device * dev, const struct component_ops * ops, int subcomponent)
register a component

Parameters

struct device * dev component device

const struct component_ops * ops component callbacks

int subcomponent nonzero identifier for subcomponents

Description

Register a new component for **dev**. Functions in **ops** will be call when the aggregate driver is ready to bind the overall driver by calling `component_bind_all()`. See also `struct component_ops`.

subcomponent must be nonzero and is used to differentiate between multiple components registerd on the same device **dev**. These components are match using `component_match_add_typed()`.

The component needs to be unregistered at driver unload/disconnect by calling `component_del()`.

See also `component_add()`.

int **component_add**(struct device * dev, const struct component_ops * ops)
register a component

Parameters

struct device * dev component device

const struct component_ops * ops component callbacks

Description

Register a new component for **dev**. Functions in **ops** will be called when the aggregate driver is ready to bind the overall driver by calling `component_bind_all()`. See also `struct component_ops`.

The component needs to be unregistered at driver unload/disconnect by calling `component_del()`.

See also `component_add_typed()` for a variant that allows multipled different components on the same device.

void **component_del**(struct device * dev, const struct component_ops * ops)
unregister a component

Parameters

struct device * dev component device

const struct component_ops * ops component callbacks

Description

Unregister a component added with `component_add()`. If the component is bound into an aggregate driver, this will force the entire aggregate driver, including all its components, to be unbound.

CHAPTER

THIRTEEN

MESSAGE-BASED DEVICES

13.1 Fusion message devices

u8 **mpt_register**(MPT_CALLBACK cbfunc, MPT_DRIVER_CLASS dclass, char * func_name)
Register protocol-specific main callback handler.

Parameters

MPT_CALLBACK cbfunc callback function pointer

MPT_DRIVER_CLASS dclass Protocol driver's class (MPT_DRIVER_CLASS enum value)

char * func_name call function's name

This routine is called by a protocol-specific driver (SCSI host, LAN, SCSI target) to register its reply callback routine. Each protocol-specific driver must do this before it will be able to use any IOC resources, such as obtaining request frames.

NOTES

The SCSI protocol driver currently calls this routine thrice in order to register separate callbacks; one for "normal" SCSI IO; one for MptScsiTaskMgmt requests; one for Scan/DV requests.

Returns u8 valued "handle" in the range (and S.O.D. order) {N,⋯,7,6,5,⋯,1} if successful. A return value of MPT_MAX_PROTOCOL_DRIVERS (including zero!) should be considered an error by the caller.

void **mpt_deregister**(u8 cb_idx)
Deregister a protocol drivers resources.

Parameters

u8 cb_idx previously registered callback handle

Each protocol-specific driver should call this routine when its module is unloaded.

int **mpt_event_register**(u8 cb_idx, MPT_EVHANDLER ev_cbfunc)
Register protocol-specific event callback handler.

Parameters

u8 cb_idx previously registered (via mpt_register) callback handle

MPT_EVHANDLER ev_cbfunc callback function

This routine can be called by one or more protocol-specific drivers if/when they choose to be notified of MPT events.

Returns 0 for success.

void **mpt_event_deregister**(u8 cb_idx)
Deregister protocol-specific event callback handler

Parameters

u8 cb_idx previously registered callback handle

Each protocol-specific driver should call this routine when it does not (or can no longer) handle events, or when its module is unloaded.

int **mpt_reset_register**(u8 cb_idx, MPT_RESETHANDLER reset_func)
Register protocol-specific IOC reset handler.

Parameters

u8 cb_idx previously registered (via mpt_register) callback handle

MPT_RESETHANDLER reset_func reset function

This routine can be called by one or more protocol-specific drivers if/when they choose to be notified of IOC resets.

Returns 0 for success.

void **mpt_reset_deregister**(u8 cb_idx)
Deregister protocol-specific IOC reset handler.

Parameters

u8 cb_idx previously registered callback handle

Each protocol-specific driver should call this routine when it does not (or can no longer) handle IOC reset handling, or when its module is unloaded.

int **mpt_device_driver_register**(struct mpt_pci_driver * dd_cbfunc, u8 cb_idx)
Register device driver hooks

Parameters

struct mpt_pci_driver * dd_cbfunc driver callbacks struct

u8 cb_idx MPT protocol driver index

void **mpt_device_driver_deregister**(u8 cb_idx)
DeRegister device driver hooks

Parameters

u8 cb_idx MPT protocol driver index

MPT_FRAME_HDR* **mpt_get_msg_frame**(u8 cb_idx, MPT_ADAPTER * ioc)
Obtain an MPT request frame from the pool

Parameters

u8 cb_idx Handle of registered MPT protocol driver

MPT_ADAPTER * ioc Pointer to MPT adapter structure

Obtain an MPT request frame from the pool (of 1024) that are allocated per MPT adapter.

Returns pointer to a MPT request frame or NULL if none are available or IOC is not active.

void **mpt_put_msg_frame**(u8 cb_idx, MPT_ADAPTER * ioc, MPT_FRAME_HDR * mf)

Send a protocol-specific MPT request frame to an IOC

Parameters

u8 cb_idx Handle of registered MPT protocol driver

MPT_ADAPTER * ioc Pointer to MPT adapter structure

MPT_FRAME_HDR * mf Pointer to MPT request frame

This routine posts an MPT request frame to the request post FIFO of a specific MPT adapter.

void **mpt_put_msg_frame_hi_pri**(u8 cb_idx, MPT_ADAPTER * ioc, MPT_FRAME_HDR * mf)

Send a hi-pri protocol-specific MPT request frame

Parameters

u8 cb_idx Handle of registered MPT protocol driver

MPT_ADAPTER * ioc Pointer to MPT adapter structure

MPT_FRAME_HDR * mf Pointer to MPT request frame

Send a protocol-specific MPT request frame to an IOC using hi-priority request queue.

This routine posts an MPT request frame to the request post FIFO of a specific MPT adapter.

void **mpt_free_msg_frame**(MPT_ADAPTER * ioc, MPT_FRAME_HDR * mf)

Place MPT request frame back on FreeQ.

Parameters

MPT_ADAPTER * ioc Pointer to MPT adapter structure

MPT_FRAME_HDR * mf Pointer to MPT request frame

This routine places a MPT request frame back on the MPT adapter's FreeQ.

int **mpt_send_handshake_request**(u8 cb_idx, MPT_ADAPTER * ioc, int reqBytes, u32 * req, int sleepFlag)

Send MPT request via doorbell handshake method.

Parameters

u8 cb_idx Handle of registered MPT protocol driver

MPT_ADAPTER * ioc Pointer to MPT adapter structure

int reqBytes Size of the request in bytes

u32 * req Pointer to MPT request frame

int sleepFlag Use schedule if CAN_SLEEP else use udelay.

This routine is used exclusively to send MptScsiTaskMgmt requests since they are required to be sent via doorbell handshake.

NOTE

It is the callers responsibility to byte-swap fields in the request which are greater than 1 byte in size.

Returns 0 for success, non-zero for failure.

int **mpt_verify_adapter**(int iocid, MPT_ADAPTER ** iocpp)
Given IOC identifier, set pointer to its adapter structure.

Parameters

int iocid IOC unique identifier (integer)

MPT_ADAPTER ** iocpp Pointer to pointer to IOC adapter

Given a unique IOC identifier, set pointer to the associated MPT adapter structure.

Returns iocid and sets iocpp if iocid is found. Returns -1 if iocid is not found.

int **mpt_attach**(struct pci_dev * pdev, const struct pci_device_id * id)
Install a PCI intelligent MPT adapter.

Parameters

struct pci_dev * pdev Pointer to pci_dev structure

const struct pci_device_id * id PCI device ID information

This routine performs all the steps necessary to bring the IOC of a MPT adapter to a OPERATIONAL state. This includes registering memory regions, registering the interrupt, and allocating request and reply memory pools.

This routine also pre-fetches the LAN MAC address of a Fibre Channel MPT adapter.

Returns 0 for success, non-zero for failure.

TODO: Add support for polled controllers

void **mpt_detach**(struct pci_dev * pdev)
Remove a PCI intelligent MPT adapter.

Parameters

struct pci_dev * pdev Pointer to pci_dev structure

int **mpt_suspend**(struct pci_dev * pdev, pm_message_t state)
Fusion MPT base driver suspend routine.

Parameters

struct pci_dev * pdev Pointer to pci_dev structure

pm_message_t state new state to enter

int **mpt_resume**(struct pci_dev * pdev)
Fusion MPT base driver resume routine.

Parameters

struct pci_dev * pdev Pointer to pci_dev structure

u32 **mpt_GetIocState**(MPT_ADAPTER * ioc, int cooked)
Get the current state of a MPT adapter.

Parameters

MPT_ADAPTER * ioc Pointer to MPT_ADAPTER structure

int cooked Request raw or cooked IOC state

Returns all IOC Doorbell register bits if cooked==0, else just the Doorbell bits in MPI_IOC_STATE_MASK.

int **mpt_alloc_fw_memory**(MPT_ADAPTER * ioc, int size)
allocate firmware memory

Parameters

MPT_ADAPTER * ioc Pointer to MPT_ADAPTER structure

int size total FW bytes

If memory has already been allocated, the same (cached) value is returned.

Return 0 if successful, or non-zero for failure

void **mpt_free_fw_memory**(MPT_ADAPTER * ioc)
free firmware memory

Parameters

MPT_ADAPTER * ioc Pointer to MPT_ADAPTER structure

If alt_img is NULL, delete from ioc structure. Else, delete a secondary image in same format.

int **mptbase_sas_persist_operation**(MPT_ADAPTER * ioc, u8 persist_opcode)
Perform operation on SAS Persistent Table

Parameters

MPT_ADAPTER * ioc Pointer to MPT_ADAPTER structure

u8 persist_opcode see below

MPI_SAS_OP_CLEAR_NOT_PRESENT	Free all persist TargetID mappings for devices not currently present.
MPI_SAS_OP_CLEAR_ALL_PERSISTENT	Clear all persist TargetID mappings

NOTE

Don’t use not this function during interrupt time.

Returns 0 for success, non-zero error

int **mpt_raid_phys_disk_pg0**(MPT_ADAPTER * ioc, u8 phys_disk_num, RaidPhysDiskPage0_t * phys_disk)
returns phys disk page zero

Parameters

MPT_ADAPTER * ioc Pointer to a Adapter Structure

u8 phys_disk_num io unit unique phys disk num generated by the ioc

RaidPhysDiskPage0_t * phys_disk requested payload data returned

Return

0 on success -EFAULT if read of config page header fails or data pointer not NULL -ENOMEM if pci_alloc failed

int **mpt_raid_phys_disk_get_num_paths**(MPT_ADAPTER * ioc, u8 phys_disk_num)
returns number paths associated to this phys_num

Parameters

MPT_ADAPTER * ioc Pointer to a Adapter Structure

u8 phys_disk_num io unit unique phys disk num generated by the ioc

Return

returns number paths

int **mpt_raid_phys_disk_pg1**(MPT_ADAPTER * ioc, u8 phys_disk_num, RaidPhysDiskPage1_t * phys_disk)
returns phys disk page 1

Parameters

MPT_ADAPTER * ioc Pointer to a Adapter Structure

u8 phys_disk_num io unit unique phys disk num generated by the ioc

RaidPhysDiskPage1_t * phys_disk requested payload data returned

Return

0 on success -EFAULT if read of config page header fails or data pointer not NULL -ENOMEM if pci_alloc failed

int **mpt_findImVolumes**(MPT_ADAPTER * ioc)
Identify IDs of hidden disks and RAID Volumes

Parameters

MPT_ADAPTER * ioc Pointer to a Adapter Strucutre

Return

0 on success -EFAULT if read of config page header fails or data pointer not NULL -ENOMEM if pci_alloc failed

int **mpt_config**(MPT_ADAPTER * ioc, CONFIGPARMS * pCfg)
Generic function to issue config message

Parameters

MPT_ADAPTER * ioc Pointer to an adapter structure

CONFIGPARMS * pCfg Pointer to a configuration structure. Struct contains action, page address, direction, physical address and pointer to a configuration page header Page header is updated.

Returns 0 for success -EPERM if not allowed due to ISR context -EAGAIN if no msg frames currently available -EFAULT for non-successful reply or no reply (timeout)

void **mpt_print_ioc_summary**(MPT_ADAPTER * ioc, char * buffer, int * size, int len, int showlan)
Write ASCII summary of IOC to a buffer.

Parameters

MPT_ADAPTER * ioc Pointer to MPT_ADAPTER structure

char * buffer Pointer to buffer where IOC summary info should be written

int * size Pointer to number of bytes we wrote (set by this routine)

int len Offset at which to start writing in buffer

int showlan Display LAN stuff?

This routine writes (english readable) ASCII text, which represents a summary of IOC information, to a buffer.

int **mpt_set_taskmgmt_in_progress_flag**(MPT_ADAPTER * ioc)
set flags associated with task management

Parameters

MPT_ADAPTER * ioc Pointer to MPT_ADAPTER structure

Returns 0 for SUCCESS or -1 if FAILED.

If -1 is return, then it was not possible to set the flags

void **mpt_clear_taskmgmt_in_progress_flag**(MPT_ADAPTER * ioc)
clear flags associated with task management

Parameters

MPT_ADAPTER * ioc Pointer to MPT_ADAPTER structure

void **mpt_halt_firmware**(MPT_ADAPTER * ioc)
Halts the firmware if it is operational and panic the kernel

Parameters

MPT_ADAPTER * ioc Pointer to MPT_ADAPTER structure

int **mpt_Soft_Hard_ResetHandler**(MPT_ADAPTER * ioc, int sleepFlag)
Try less expensive reset

Parameters

MPT_ADAPTER * ioc Pointer to MPT_ADAPTER structure

int sleepFlag Indicates if sleep or schedule must be called.

Returns 0 for SUCCESS or -1 if FAILED. Try for softreset first, only if it fails go for expensive HardReset.

int **mpt_HardResetHandler**(MPT_ADAPTER * ioc, int sleepFlag)
Generic reset handler

Parameters

MPT_ADAPTER * ioc Pointer to MPT_ADAPTER structure

int sleepFlag Indicates if sleep or schedule must be called.

Issues SCSI Task Management call based on input arg values. If TaskMgmt fails, returns associated SCSI request.

Remark: _HardResetHandler can be invoked from an interrupt thread (timer) or a non-interrupt thread. In the former, must not call schedule().

Note

A return of -1 is a FATAL error case, as it means a FW reload/initialization failed.

Returns 0 for SUCCESS or -1 if FAILED.

const char * **mptscsih_info**(struct Scsi_Host * SChost)
Return information about MPT adapter

Parameters

struct Scsi_Host * SChost Pointer to Scsi_Host structure

(linux scsi_host_template.info routine)

Returns pointer to buffer where information was written.

int **mptscsih_qcmd**(struct scsi_cmnd * SCpnt)
Primary Fusion MPT SCSI initiator IO start routine.

Parameters

struct scsi_cmnd * SCpnt Pointer to scsi_cmnd structure

(linux scsi_host_template.queuecommand routine) This is the primary SCSI IO start routine. Create a MPI SCSIIORequest from a linux scsi_cmnd request and send it to the IOC.

Returns 0. (rtn value discarded by linux scsi mid-layer)

int **mptscsih_IssueTaskMgmt**(MPT_SCSI_HOST * hd, u8 type, u8 channel,
u8 id, u64 lun, int ctx2abort, ulong timeout)
Generic send Task Management function.

Parameters

MPT_SCSI_HOST * hd Pointer to MPT_SCSI_HOST structure

u8 type Task Management type

u8 channel channel number for task management

u8 id Logical Target ID for reset (if appropriate)

u64 lun Logical Unit for reset (if appropriate)

int ctx2abort Context for the task to be aborted (if appropriate)

ulong timeout timeout for task management control

Remark: _HardResetHandler can be invoked from an interrupt thread (timer) or a non-interrupt thread. In the former, must not call schedule().

Not all fields are meaningfull for all task types.

Returns 0 for SUCCESS, or FAILED.

int **mptscsih_abort**(struct scsi_cmnd * SCpnt)
Abort linux scsi_cmnd routine, new_eh variant

Parameters

struct scsi_cmnd * SCpnt Pointer to scsi_cmnd structure, IO to be aborted

(linux scsi_host_template.eh_abort_handler routine)

Returns SUCCESS or FAILED.

int **mptscsih_dev_reset**(struct scsi_cmnd * SCpnt)
Perform a SCSI TARGET_RESET! new_eh variant

Parameters

struct scsi_cmnd * SCpnt Pointer to scsi_cmnd structure, IO which reset is due to

(linux scsi_host_template.eh_dev_reset_handler routine)

Returns SUCCESS or FAILED.

int **mptscsih_bus_reset**(struct scsi_cmnd * SCpnt)
Perform a SCSI BUS_RESET! new_eh variant

Parameters

struct scsi_cmnd * SCpnt Pointer to scsi_cmnd structure, IO which reset is due to

(linux scsi_host_template.eh_bus_reset_handler routine)

Returns SUCCESS or FAILED.

int **mptscsih_host_reset**(struct scsi_cmnd * SCpnt)
Perform a SCSI host adapter RESET (new_eh variant)

Parameters

struct scsi_cmnd * SCpnt Pointer to scsi_cmnd structure, IO which reset is due to

(linux scsi_host_template.eh_host_reset_handler routine)

Returns SUCCESS or FAILED.

int **mptscsih_taskmgmt_complete**(MPT_ADAPTER * ioc, MPT_FRAME_HDR * mf, MPT_FRAME_HDR * mr)
Registered with Fusion MPT base driver

Parameters

MPT_ADAPTER * ioc Pointer to MPT_ADAPTER structure

MPT_FRAME_HDR * mf Pointer to SCSI task mgmt request frame

MPT_FRAME_HDR * mr Pointer to SCSI task mgmt reply frame

This routine is called from mptbase.c::mpt_interrupt() at the completion of any SCSI task management request. This routine is registered with the MPT (base) driver at driver load/init time via the `mpt_register()` API call.

Returns 1 indicating alloc'd request frame ptr should be freed.

struct scsi_cmnd * **mptscsih_get_scsi_lookup**(MPT_ADAPTER * ioc, int i)
retrieves scmd entry

Parameters

MPT_ADAPTER * ioc Pointer to MPT_ADAPTER structure

int i index into the array

Description

Returns the scsi_cmd pointer

CHAPTER

FOURTEEN

INFINIBAND AND REMOTE DMA (RDMA) INTERFACES

14.1 Introduction and Overview

TBD

14.2 InfiniBand core interfaces

struct iwpm_nlmsg_request * **iwpm_get_nlmsg_request**(__u32 nlmsg_seq,
u8 nl_client,
gfp_t gfp)

Allocate and initialize netlink message request

Parameters

__u32 nlmsg_seq Sequence number of the netlink message

u8 nl_client The index of the netlink client

gfp_t gfp Indicates how the memory for the request should be allocated

Description

Returns the newly allocated netlink request object if successful, otherwise returns NULL

void **iwpm_free_nlmsg_request**(struct kref * kref)

Deallocate netlink message request

Parameters

struct kref * kref Holds reference of netlink message request

struct iwpm_nlmsg_request * **iwpm_find_nlmsg_request**(__u32 echo_seq)

Find netlink message request in the request list

Parameters

__u32 echo_seq Sequence number of the netlink request to find

Description

Returns the found netlink message request, if not found, returns NULL

int **iwpm_wait_complete_req**(struct iwpm_nlmsg_request * nlmsg_request)

Block while servicing the netlink request

Parameters

struct iwpm_nlmsg_request * nlmsg_request Netlink message request to service

Description

Wakes up, after the request is completed or expired Returns 0 if the request is complete without error

int **iwpm_get_nlmsg_seq**(void)
Get the sequence number for a netlink message to send to the port mapper

Parameters

void no arguments

Description

Returns the sequence number for the netlink message.

void **iwpm_add_remote_info**(struct iwpm_remote_info * reminfo)
Add remote address info of the connecting peer to the remote info hash table

Parameters

struct iwpm_remote_info * reminfo The remote info to be added

int **iwpm_valid_client**(u8 nl_client)
Check if the port mapper client is valid

Parameters

u8 nl_client The index of the netlink client

Description

Valid clients need to call iwpm_init() before using the port mapper

void **iwpm_set_valid**(u8 nl_client, int valid)
Set the port mapper client to valid or not

Parameters

u8 nl_client The index of the netlink client

int valid 1 if valid or 0 if invalid

u32 **iwpm_check_registration**(u8 nl_client, u32 reg)
Check if the client registration matches the given one

Parameters

u8 nl_client The index of the netlink client

u32 reg The given registration type to compare with

Description

Call iwpm_register_pid() to register a client Returns true if the client registration matches reg, otherwise returns false

void **iwpm_set_registration**(u8 nl_client, u32 reg)
Set the client registration

Parameters

u8 nl_client The index of the netlink client

u32 reg Registration type to set

u32 **iwpm_get_registration**(u8 nl_client)

Parameters

u8 nl_client The index of the netlink client

Description

Returns the client registration type

int **iwpm_send_mapinfo**(u8 nl_client, int iwpm_pid)
Send local and mapped IPv4/IPv6 address info of a client to the user space port mapper

Parameters

u8 nl_client The index of the netlink client

int iwpm_pid The pid of the user space port mapper

Description

If successful, returns the number of sent mapping info records

int **iwpm_mapinfo_available**(void)
Check if any mapping info records is available in the hash table

Parameters

void no arguments

Description

Returns 1 if mapping information is available, otherwise returns 0

int **iwpm_compare_sockaddr**(struct sockaddr_storage * a_sockaddr, struct sockaddr_storage * b_sockaddr)
Compare two sockaddr storage structs

Parameters

struct sockaddr_storage * a_sockaddr first sockaddr to compare

struct sockaddr_storage * b_sockaddr second sockaddr to compare

Return

0 if they are holding the same ip/tcp address info, otherwise returns 1

int **iwpm_validate_nlmsg_attr**(struct nlattr * nltb, int nla_count)
Check for NULL netlink attributes

Parameters

struct nlattr * nltb Holds address of each netlink message attributes

int nla_count Number of netlink message attributes

Description

Returns error if any of the nla_count attributes is NULL

struct sk_buff * **iwpm_create_nlmsg**(u32 nl_op, struct nlmsghdr ** nlh, int nl_client)
Allocate skb and form a netlink message

Parameters

u32 nl_op Netlink message opcode

struct nlmsghdr ** nlh Holds address of the netlink message header in skb

int nl_client The index of the netlink client

Description

Returns the newly allcated skb, or NULL if the tailroom of the skb is insufficient to store the message header and payload

int **iwpm_parse_nlmsg**(struct netlink_callback * cb, int policy_max, const struct nla_policy * nlmsg_policy, struct nlattr * nltb, const char * msg_type)
Validate and parse the received netlink message

Parameters

struct netlink_callback * cb Netlink callback structure

int policy_max Maximum attribute type to be expected

const struct nla_policy * nlmsg_policy Validation policy

struct nlattr * nltb Array to store policy_max parsed elements

const char * msg_type Type of netlink message

Description

Returns 0 on success or a negative error code

void **iwpm_print_sockaddr**(struct sockaddr_storage * sockaddr, char * msg)
Print IPv4/IPv6 address and TCP port

Parameters

struct sockaddr_storage * sockaddr Socket address to print

char * msg Message to print

int **iwpm_send_hello**(u8 nl_client, int iwpm_pid, u16 abi_version)
Send hello response to iwpmd

Parameters

u8 nl_client The index of the netlink client

int iwpm_pid The pid of the user space port mapper

u16 abi_version The kernel's abi_version

Description

Returns 0 on success or a negative error code

int **ib_process_cq_direct**(struct ib_cq * cq, int budget)
process a CQ in caller context

Parameters

struct ib_cq * cq CQ to process

int budget number of CQEs to poll for

Description

This function is used to process all outstanding CQ entries. It does not offload CQ processing to a different context and does not ask for completion interrupts from the HCA. Using direct processing on CQ with non IB_POLL_DIRECT type may trigger concurrent processing.

Note

do not pass -1 as `budget` unless it is guaranteed that the number of completions that will be processed is small.

struct ib_cq * **__ib_alloc_cq_user**(struct ib_device * dev, void * private, int nr_cqe, int comp_vector, enum ib_poll_context poll_ctx, const char * caller, struct ib_udata * udata)
allocate a completion queue

Parameters

struct ib_device * dev device to allocate the CQ for

void * private driver private data, accessible from cq->cq_context

int nr_cqe number of CQEs to allocate

int comp_vector HCA completion vectors for this CQ

enum ib_poll_context poll_ctx context to poll the CQ from.

const char * caller module owner name.

struct ib_udata * udata Valid user data or NULL for kernel object

Description

This is the proper interface to allocate a CQ for in-kernel users. A CQ allocated with this interface will automatically be polled from the specified context. The ULP must use wr->wr_cqe instead of wr->wr_id to use this CQ abstraction.

struct ib_cq * **__ib_alloc_cq_any**(struct ib_device * dev, void * private, int nr_cqe, enum ib_poll_context poll_ctx, const char * caller)
allocate a completion queue

Parameters

struct ib_device * dev device to allocate the CQ for

void * private driver private data, accessible from cq->cq_context

int nr_cqe number of CQEs to allocate

enum ib_poll_context poll_ctx context to poll the CQ from

const char * caller module owner name

Description

Attempt to spread ULP Completion Queues over each device's interrupt vectors. A simple best-effort mechanism is used.

void **ib_free_cq_user**(struct ib_cq * cq, struct ib_udata * udata)
free a completion queue

Parameters

struct ib_cq * cq completion queue to free.

struct ib_udata * udata User data or NULL for kernel object

struct ib_cq * **ib_cq_pool_get**(struct ib_device * dev, unsigned int nr_cqe, int comp_vector_hint, enum ib_poll_context poll_ctx)
Find the least used completion queue that matches a given cpu hint (or least used for wild card affinity) and fits nr_cqe.

Parameters

struct ib_device * dev rdma device

unsigned int nr_cqe number of needed cqe entries

int comp_vector_hint completion vector hint (-1) for the driver to assign a comp vector based on internal counter

enum ib_poll_context poll_ctx cq polling context

Description

Finds a cq that satisfies **comp_vector_hint** and **nr_cqe** requirements and claim entries in it for us. In case there is no available cq, allocate a new cq with the requirements and add it to the device pool. IB_POLL_DIRECT cannot be used for shared cqs so it is not a valid value for **poll_ctx**.

void **ib_cq_pool_put**(struct ib_cq * cq, unsigned int nr_cqe)
Return a CQ taken from a shared pool.

Parameters

struct ib_cq * cq The CQ to return.

unsigned int nr_cqe The max number of cqes that the user had requested.

int **ib_cm_listen**(struct ib_cm_id * cm_id, __be64 service_id, __be64 service_mask)
Initiates listening on the specified service ID for connection and service ID resolution requests.

Parameters

struct ib_cm_id * cm_id Connection identifier associated with the listen request.

__be64 service_id Service identifier matched against incoming connection and service ID resolution requests. The service ID should be specified network-

byte order. If set to IB_CM_ASSIGN_SERVICE_ID, the CM will assign a service ID to the caller.

__be64 service_mask Mask applied to service ID used to listen across a range of service IDs. If set to 0, the service ID is matched exactly. This parameter is ignored if `service_id` is set to IB_CM_ASSIGN_SERVICE_ID.

struct ib_cm_id * **ib_cm_insert_listen**(struct ib_device * device, ib_cm_handler cm_handler, __be64 service_id)

Parameters

struct ib_device * device Device associated with the cm_id. All related communication will be associated with the specified device.

ib_cm_handler cm_handler Callback invoked to notify the user of CM events.

__be64 service_id Service identifier matched against incoming connection and service ID resolution requests. The service ID should be specified network-byte order. If set to IB_CM_ASSIGN_SERVICE_ID, the CM will assign a service ID to the caller.

Description

If there's an existing ID listening on that same device and service ID, return it.

Callers should call ib_destroy_cm_id when done with the listener ID.

int **rdma_rw_ctx_init**(struct rdma_rw_ctx * ctx, struct ib_qp * qp, u8 port_num, struct scatterlist * sg, u32 sg_cnt, u32 sg_offset, u64 remote_addr, u32 rkey, enum dma_data_direction dir)

initialize a RDMA READ/WRITE context

Parameters

struct rdma_rw_ctx * ctx context to initialize

struct ib_qp * qp queue pair to operate on

u8 port_num port num to which the connection is bound

struct scatterlist * sg scatterlist to READ/WRITE from/to

u32 sg_cnt number of entries in **sg**

u32 sg_offset current byte offset into **sg**

u64 remote_addr remote address to read/write (relative to **rkey**)

u32 rkey remote key to operate on

enum dma_data_direction dir `DMA_TO_DEVICE` for RDMA WRITE, `DMA_FROM_DEVICE` for RDMA READ

Description

Returns the number of WQEs that will be needed on the workqueue if successful, or a negative error code.

int **rdma_rw_ctx_signature_init**(struct rdma_rw_ctx * ctx, struct ib_qp * qp, u8 port_num, struct scatterlist * sg, u32 sg_cnt, struct scatterlist * prot_sg, u32 prot_sg_cnt, struct ib_sig_attrs * sig_attrs, u64 remote_addr, u32 rkey, enum dma_data_direction dir)

initialize a RW context with signature offload

Parameters

struct rdma_rw_ctx * ctx context to initialize

struct ib_qp * qp queue pair to operate on

u8 port_num port num to which the connection is bound

struct scatterlist * sg scatterlist to READ/WRITE from/to

u32 sg_cnt number of entries in **sg**

struct scatterlist * prot_sg scatterlist to READ/WRITE protection information from/to

u32 prot_sg_cnt number of entries in **prot_sg**

struct ib_sig_attrs * sig_attrs signature offloading algorithms

u64 remote_addr remote address to read/write (relative to **rkey**)

u32 rkey remote key to operate on

enum dma_data_direction dir `DMA_TO_DEVICE` for RDMA WRITE, `DMA_FROM_DEVICE` for RDMA READ

Description

Returns the number of WQEs that will be needed on the workqueue if successful, or a negative error code.

struct ib_send_wr * **rdma_rw_ctx_wrs**(struct rdma_rw_ctx * ctx, struct ib_qp * qp, u8 port_num, struct ib_cqe * cqe, struct ib_send_wr * chain_wr)

return chain of WRs for a RDMA READ or WRITE operation

Parameters

struct rdma_rw_ctx * ctx context to operate on

struct ib_qp * qp queue pair to operate on

u8 port_num port num to which the connection is bound

struct ib_cqe * cqe completion queue entry for the last WR

struct ib_send_wr * chain_wr WR to append to the posted chain

Description

Return the WR chain for the set of RDMA READ/WRITE operations described by **ctx**, as well as any memory registration operations needed. If **chain_wr** is non-NULL the WR it points to will be appended to the chain of WRs posted. If **chain_wr** is not set **cqe** must be set so that the caller gets a completion notification.

int **rdma_rw_ctx_post**(struct rdma_rw_ctx * ctx, struct ib_qp * qp, u8 port_num, struct ib_cqe * cqe, struct ib_send_wr * chain_wr)

post a RDMA READ or RDMA WRITE operation

Parameters

struct rdma_rw_ctx * ctx context to operate on

struct ib_qp * qp queue pair to operate on

u8 port_num port num to which the connection is bound

struct ib_cqe * cqe completion queue entry for the last WR

struct ib_send_wr * chain_wr WR to append to the posted chain

Description

Post the set of RDMA READ/WRITE operations described by **ctx**, as well as any memory registration operations needed. If **chain_wr** is non-NULL the WR it points to will be appended to the chain of WRs posted. If **chain_wr** is not set **cqe** must be set so that the caller gets a completion notification.

void **rdma_rw_ctx_destroy**(struct rdma_rw_ctx * ctx, struct ib_qp * qp, u8 port_num, struct scatterlist * sg, u32 sg_cnt, enum dma_data_direction dir)

release all resources allocated by rdma_rw_ctx_init

Parameters

struct rdma_rw_ctx * ctx context to release

struct ib_qp * qp queue pair to operate on

u8 port_num port num to which the connection is bound

struct scatterlist * sg scatterlist that was used for the READ/WRITE

u32 sg_cnt number of entries in **sg**

enum dma_data_direction dir `DMA_TO_DEVICE` for RDMA WRITE, `DMA_FROM_DEVICE` for RDMA READ

void **rdma_rw_ctx_destroy_signature**(struct rdma_rw_ctx * ctx, struct ib_qp * qp, u8 port_num, struct scatterlist * sg, u32 sg_cnt, struct scatterlist * prot_sg, u32 prot_sg_cnt, enum dma_data_direction dir)

release all resources allocated by rdma_rw_ctx_signature_init

Parameters

struct rdma_rw_ctx * ctx context to release

struct ib_qp * qp queue pair to operate on

u8 port_num port num to which the connection is bound

struct scatterlist * sg scatterlist that was used for the READ/WRITE

u32 sg_cnt number of entries in **sg**

struct scatterlist * prot_sg scatterlist that was used for the READ/WRITE of the PI

u32 prot_sg_cnt number of entries in **prot_sg**

enum dma_data_direction dir DMA_TO_DEVICE for RDMA WRITE, DMA_FROM_DEVICE for RDMA READ

unsigned int **rdma_rw_mr_factor**(struct ib_device * device, u8 port_num, unsigned int maxpages)
return number of MRs required for a payload

Parameters

struct ib_device * device device handling the connection

u8 port_num port num to which the connection is bound

unsigned int maxpages maximum payload pages per rdma_rw_ctx

Description

Returns the number of MRs the device requires to move **maxpayload** bytes. The returned value is used during transport creation to compute max_rdma_ctxts and the size of the transport's Send and Send Completion Queues.

bool **rdma_dev_access_netns**(const struct ib_device * dev, const struct net * net)
Return whether an rdma device can be accessed from a specified net namespace or not.

Parameters

const struct ib_device * dev Pointer to rdma device which needs to be checked

const struct net * net Pointer to net namesapce for which access to be checked

Description

When the rdma device is in shared mode, it ignores the net namespace. When the rdma device is exclusive to a net namespace, rdma device net namespace is checked against the specified one.

void **ib_device_put**(struct ib_device * device)
Release IB device reference

Parameters

struct ib_device * device device whose reference to be released

Description

ib_device_put() releases reference to the IB device to allow it to be unregistered and eventually free.

struct ib_device * **ib_device_get_by_name**(const char * name, enum rdma_driver_id driver_id)
Find an IB device by name

Parameters

const char * name The name to look for

enum rdma_driver_id driver_id The driver ID that must match (RDMA_DRIVER_UNKNOWN matches all)

Description

Find and hold an ib_device by its name. The caller must call `ib_device_put()` on the returned pointer.

struct ib_device * **_ib_alloc_device**(size_t size)
allocate an IB device struct

Parameters

size_t size size of structure to allocate

Description

Low-level drivers should use ib_alloc_device() to allocate `struct ib_device`. **size** is the size of the structure to be allocated, including any private data used by the low-level driver. `ib_dealloc_device()` must be used to free structures allocated with ib_alloc_device().

void **ib_dealloc_device**(struct ib_device * device)
free an IB device struct

Parameters

struct ib_device * device structure to free

Description

Free a structure allocated with ib_alloc_device().

int **ib_register_device**(struct ib_device * device, const char * name)
Register an IB device with IB core

Parameters

struct ib_device * device Device to register

const char * name unique string device name. This may include a '%' which will cause a unique index to be added to the passed device name.

Description

Low-level drivers use `ib_register_device()` to register their devices with the IB core. All registered clients will receive a callback for each device that is added. **device** must be allocated with ib_alloc_device().

If the driver uses ops.dealloc_driver and calls any `ib_unregister_device()` asynchronously then the device pointer may become freed as soon as this function returns.

void **ib_unregister_device**(struct ib_device * ib_dev)
Unregister an IB device

Parameters

struct ib_device * ib_dev The device to unregister

Description

Unregister an IB device. All clients will receive a remove callback.

Callers should call this routine only once, and protect against races with registration. Typically it should only be called as part of a remove callback in an implementation of driver core' s struct device_driver and related.

If ops.dealloc_driver is used then ib_dev will be freed upon return from this function.

void **ib_unregister_device_and_put**(struct ib_device * ib_dev)
Unregister a device while holding a 'get'

Parameters

struct ib_device * ib_dev The device to unregister

Description

This is the same as `ib_unregister_device()`, except it includes an internal `ib_device_put()` that should match a 'get' obtained by the caller.

It is safe to call this routine concurrently from multiple threads while holding the 'get' . When the function returns the device is fully unregistered.

Drivers using this flow MUST use the driver_unregister callback to clean up their resources associated with the device and dealloc it.

void **ib_unregister_driver**(enum rdma_driver_id driver_id)
Unregister all IB devices for a driver

Parameters

enum rdma_driver_id driver_id The driver to unregister

Description

This implements a fence for device unregistration. It only returns once all devices associated with the driver_id have fully completed their unregistration and returned from ib_unregister_device*().

If device' s are not yet unregistered it goes ahead and starts unregistering them.

This does not block creation of new devices with the given driver_id, that is the responsibility of the caller.

void **ib_unregister_device_queued**(struct ib_device * ib_dev)
Unregister a device using a work queue

Parameters

struct ib_device * ib_dev The device to unregister

Description

This schedules an asynchronous unregistration using a WQ for the device. A driver should use this to avoid holding locks while doing unregistration, such as holding the RTNL lock.

Drivers using this API must use ib_unregister_driver before module unload to ensure that all scheduled unregistrations have completed.

int **ib_register_client**(struct ib_client * client)
Register an IB client

Parameters

struct ib_client * client Client to register

Description

Upper level users of the IB drivers can use `ib_register_client()` to register callbacks for IB device addition and removal. When an IB device is added, each registered client's add method will be called (in the order the clients were registered), and when a device is removed, each client's remove method will be called (in the reverse order that clients were registered). In addition, when `ib_register_client()` is called, the client will receive an add callback for all devices already registered.

void **ib_unregister_client**(struct ib_client * client)
Unregister an IB client

Parameters

struct ib_client * client Client to unregister

Description

Upper level users use `ib_unregister_client()` to remove their client registration. When `ib_unregister_client()` is called, the client will receive a remove callback for each IB device still registered.

This is a full fence, once it returns no client callbacks will be called, or are running in another thread.

void **ib_set_client_data**(struct ib_device * device, struct ib_client * client,
void * data)
Set IB client context

Parameters

struct ib_device * device Device to set context for

struct ib_client * client Client to set context for

void * data Context to set

Description

`ib_set_client_data()` sets client context data that can be retrieved with ib_get_client_data(). This can only be called while the client is registered to the device, once the ib_client remove() callback returns this cannot be called.

void **ib_register_event_handler**(struct ib_event_handler * event_handler)
Register an IB event handler

Parameters

struct ib_event_handler * event_handler Handler to register

Description

`ib_register_event_handler()` registers an event handler that will be called back when asynchronous IB events occur (as defined in chapter 11 of the InfiniBand Architecture Specification). This callback occurs in workqueue context.

void **ib_unregister_event_handler**(struct ib_event_handler * event_handler)

Unregister an event handler

Parameters

struct ib_event_handler * event_handler Handler to unregister

Description

Unregister an event handler registered with `ib_register_event_handler()`.

int **ib_query_port**(struct ib_device * device, u8 port_num, struct ib_port_attr * port_attr)

Query IB port attributes

Parameters

struct ib_device * device Device to query

u8 port_num Port number to query

struct ib_port_attr * port_attr Port attributes

Description

`ib_query_port()` returns the attributes of a port through the **port_attr** pointer.

int **ib_device_set_netdev**(struct ib_device * ib_dev, struct net_device * ndev, unsigned int port)

Associate the ib_dev with an underlying net_device

Parameters

struct ib_device * ib_dev Device to modify

struct net_device * ndev net_device to affiliate, may be NULL

unsigned int port IB port the net_device is connected to

Description

Drivers should use this to link the ib_device to a netdev so the netdev shows up in interfaces like ib_enum_roce_netdev. Only one netdev may be affiliated with any port.

The caller must ensure that the given ndev is not unregistered or unregistering, and that either the ib_device is unregistered or `ib_device_set_netdev()` is called with NULL when the ndev sends a NETDEV_UNREGISTER event.

struct ib_device * **ib_device_get_by_netdev**(struct net_device * ndev, enum rdma_driver_id driver_id)

Find an IB device associated with a netdev

Parameters

struct net_device * ndev netdev to locate

enum rdma_driver_id driver_id The driver ID that must match (RDMA_DRIVER_UNKNOWN matches all)

Description

Find and hold an ib_device that is associated with a netdev via `ib_device_set_netdev()`. The caller must call `ib_device_put()` on the returned pointer.

int **ib_query_pkey**(struct ib_device * device, u8 port_num, u16 index, u16 * pkey)
Get P_Key table entry

Parameters

struct ib_device * device Device to query

u8 port_num Port number to query

u16 index P_Key table index to query

u16 * pkey Returned P_Key

Description

`ib_query_pkey()` fetches the specified P_Key table entry.

int **ib_modify_device**(struct ib_device * device, int device_modify_mask, struct ib_device_modify * device_modify)
Change IB device attributes

Parameters

struct ib_device * device Device to modify

int device_modify_mask Mask of attributes to change

struct ib_device_modify * device_modify New attribute values

Description

`ib_modify_device()` changes a device's attributes as specified by the **device_modify_mask** and **device_modify** structure.

int **ib_modify_port**(struct ib_device * device, u8 port_num, int port_modify_mask, struct ib_port_modify * port_modify)
Modifies the attributes for the specified port.

Parameters

struct ib_device * device The device to modify.

u8 port_num The number of the port to modify.

int port_modify_mask Mask used to specify which attributes of the port to change.

struct ib_port_modify * port_modify New attribute values for the port.

Description

`ib_modify_port()` changes a port's attributes as specified by the **port_modify_mask** and **port_modify** structure.

int **ib_find_gid**(struct ib_device * device, union ib_gid * gid, u8 * port_num, u16 * index)

Returns the port number and GID table index where a specified GID value occurs. Its searches only for IB link layer.

Parameters

struct ib_device * device The device to query.

union ib_gid * gid The GID value to search for.

u8 * port_num The port number of the device where the GID value was found.

u16 * index The index into the GID table where the GID was found. This parameter may be NULL.

int **ib_find_pkey**(struct ib_device * device, u8 port_num, u16 pkey, u16 * index)

Returns the PKey table index where a specified PKey value occurs.

Parameters

struct ib_device * device The device to query.

u8 port_num The port number of the device to search for the PKey.

u16 pkey The PKey value to search for.

u16 * index The index into the PKey table where the PKey was found.

struct net_device * **ib_get_net_dev_by_params**(struct ib_device * dev, u8 port, u16 pkey, const union ib_gid * gid, const struct sockaddr * addr)

Return the appropriate net_dev for a received CM request

Parameters

struct ib_device * dev An RDMA device on which the request has been received.

u8 port Port number on the RDMA device.

u16 pkey The Pkey the request came on.

const union ib_gid * gid A GID that the net_dev uses to communicate.

const struct sockaddr * addr Contains the IP address that the request specified as its destination.

struct ib_pd * **__ib_alloc_pd**(struct ib_device * device, unsigned int flags, const char * caller)

Allocates an unused protection domain.

Parameters

struct ib_device * device The device on which to allocate the protection domain.

unsigned int flags protection domain flags

const char * caller caller's build-time module name

Description

A protection domain object provides an association between QPs, shared receive queues, address handles, memory regions, and memory windows.

Every PD has a local_dma_lkey which can be used as the lkey value for local memory operations.

void **ib_dealloc_pd_user**(struct ib_pd * pd, struct ib_udata * udata)
Deallocates a protection domain.

Parameters

struct ib_pd * pd The protection domain to deallocate.

struct ib_udata * udata Valid user data or NULL for kernel object

Description

It is an error to call this function while any resources in the pd still exist. The caller is responsible to synchronously destroy them and guarantee no new allocations will happen.

void **rdma_copy_ah_attr**(struct rdma_ah_attr * dest, const struct rdma_ah_attr * src)
Copy rdma ah attribute from source to destination.

Parameters

struct rdma_ah_attr * dest Pointer to destination ah_attr. Contents of the destination pointer is assumed to be invalid and attribute are overwritten.

const struct rdma_ah_attr * src Pointer to source ah_attr.

void **rdma_replace_ah_attr**(struct rdma_ah_attr * old, const struct rdma_ah_attr * new)
Replace valid ah_attr with new new one.

Parameters

struct rdma_ah_attr * old Pointer to existing ah_attr which needs to be replaced. old is assumed to be valid or zero'd

const struct rdma_ah_attr * new Pointer to the new ah_attr.

Description

`rdma_replace_ah_attr()` first releases any reference in the old ah_attr if old the ah_attr is valid; after that it copies the new attribute and holds the reference to the replaced ah_attr.

void **rdma_move_ah_attr**(struct rdma_ah_attr * dest, struct rdma_ah_attr * src)
Move ah_attr pointed by source to destination.

Parameters

struct rdma_ah_attr * dest Pointer to destination ah_attr to copy to. dest is assumed to be valid or zero'd

struct rdma_ah_attr * src Pointer to the new ah_attr.

Description

`rdma_move_ah_attr()` first releases any reference in the destination ah_attr if it is valid. This also transfers ownership of internal references from src to dest, making src invalid in the process. No new reference of the src ah_attr is taken.

struct ib_ah * **rdma_create_ah**(struct ib_pd * pd, struct rdma_ah_attr * ah_attr, u32 flags)

Creates an address handle for the given address vector.

Parameters

struct ib_pd * pd The protection domain associated with the address handle.

struct rdma_ah_attr * ah_attr The attributes of the address vector.

u32 flags Create address handle flags (see enum rdma_create_ah_flags).

Description

It returns 0 on success and returns appropriate error code on error. The address handle is used to reference a local or global destination in all UD QP post sends.

struct ib_ah * **rdma_create_user_ah**(struct ib_pd * pd, struct rdma_ah_attr * ah_attr, struct ib_udata * udata)

Creates an address handle for the given address vector. It resolves destination mac address for ah attribute of RoCE type.

Parameters

struct ib_pd * pd The protection domain associated with the address handle.

struct rdma_ah_attr * ah_attr The attributes of the address vector.

struct ib_udata * udata pointer to user's input output buffer information need by provider driver.

Description

It returns 0 on success and returns appropriate error code on error. The address handle is used to reference a local or global destination in all UD QP post sends.

void **rdma_move_grh_sgid_attr**(struct rdma_ah_attr * attr, union ib_gid * dgid, u32 flow_label, u8 hop_limit, u8 traffic_class, const struct ib_gid_attr * sgid_attr)

Sets the sgid attribute of GRH, taking ownership of the reference

Parameters

struct rdma_ah_attr * attr Pointer to AH attribute structure

union ib_gid * dgid Destination GID

u32 flow_label Flow label

u8 hop_limit Hop limit

u8 traffic_class traffic class

const struct ib_gid_attr * sgid_attr Pointer to SGID attribute

Description

This takes ownership of the sgid_attr reference. The caller must ensure `rdma_destroy_ah_attr()` is called before destroying the rdma_ah_attr after calling this function.

void **rdma_destroy_ah_attr**(struct rdma_ah_attr * ah_attr)
Release reference to SGID attribute of ah attribute.

Parameters

struct rdma_ah_attr * ah_attr Pointer to ah attribute

Description

Release reference to the SGID attribute of the ah attribute if it is non NULL. It is safe to call this multiple times, and safe to call it on a zero initialized ah_attr.

struct ib_srq * **ib_create_srq_user**(struct ib_pd * pd, struct ib_srq_init_attr * srq_init_attr, struct ib_usrq_object * uobject, struct ib_udata * udata)
Creates a SRQ associated with the specified protection domain.

Parameters

struct ib_pd * pd The protection domain associated with the SRQ.

struct ib_srq_init_attr * srq_init_attr A list of initial attributes required to create the SRQ. If SRQ creation succeeds, then the attributes are updated to the actual capabilities of the created SRQ. **uobject** - uobject pointer if this is not a kernel SRQ **udata** - udata pointer if this is not a kernel SRQ

struct ib_usrq_object * uobject undescribed

struct ib_udata * udata undescribed

Description

srq_attr->max_wr and srq_attr->max_sge are read the determine the requested size of the SRQ, and set to the actual values allocated on return. If ib_create_srq() succeeds, then max_wr and max_sge will always be at least as large as the requested values.

struct ib_qp * **ib_create_qp**(struct ib_pd * pd, struct ib_qp_init_attr * qp_init_attr)
Creates a kernel QP associated with the specified protection domain.

Parameters

struct ib_pd * pd The protection domain associated with the QP.

struct ib_qp_init_attr * qp_init_attr A list of initial attributes required to create the QP. If QP creation succeeds, then the attributes are updated to the actual capabilities of the created QP.

NOTE

for user qp use ib_create_qp_user with valid udata!

int **ib_modify_qp_with_udata**(struct ib_qp * ib_qp, struct ib_qp_attr * attr, int attr_mask, struct ib_udata * udata)
Modifies the attributes for the specified QP.

Parameters

struct ib_qp * ib_qp The QP to modify.

struct ib_qp_attr * attr On input, specifies the QP attributes to modify. On output, the current values of selected QP attributes are returned.

int attr_mask A bit-mask used to specify which attributes of the QP are being modified.

struct ib_udata * udata pointer to user's input output buffer information are being modified. It returns 0 on success and returns appropriate error code on error.

struct ib_mr * **ib_alloc_mr_user**(struct ib_pd * pd, enum ib_mr_type mr_type, u32 max_num_sg, struct ib_udata * udata)

Allocates a memory region

Parameters

struct ib_pd * pd protection domain associated with the region

enum ib_mr_type mr_type memory region type

u32 max_num_sg maximum sg entries available for registration.

struct ib_udata * udata user data or null for kernel objects

Notes

Memory registeration page/sg lists must not exceed max_num_sg. For mr_type IB_MR_TYPE_MEM_REG, the total length cannot exceed max_num_sg * used_page_size.

struct ib_mr * **ib_alloc_mr_integrity**(struct ib_pd * pd, u32 max_num_data_sg, u32 max_num_meta_sg)

Allocates an integrity memory region

Parameters

struct ib_pd * pd protection domain associated with the region

u32 max_num_data_sg maximum data sg entries available for registration

u32 max_num_meta_sg maximum metadata sg entries available for registration

Notes

Memory registration page/sg lists must not exceed max_num_sg, also the integrity page/sg lists must not exceed max_num_meta_sg.

struct ib_wq * **ib_create_wq**(struct ib_pd * pd, struct ib_wq_init_attr * wq_attr)

Creates a WQ associated with the specified protection domain.

Parameters

struct ib_pd * pd The protection domain associated with the WQ.

struct ib_wq_init_attr * wq_attr A list of initial attributes required to create the WQ. If WQ creation succeeds, then the attributes are updated to the actual capabilities of the created WQ.

Description

wq_attr->max_wr and wq_attr->max_sge determine the requested size of the WQ, and set to the actual values allocated on return. If `ib_create_wq()` succeeds, then max_wr and max_sge will always be at least as large as the requested values.

int **ib_destroy_wq**(struct ib_wq * wq, struct ib_udata * udata)
Destroys the specified user WQ.

Parameters

struct ib_wq * wq The WQ to destroy.

struct ib_udata * udata Valid user data

int **ib_modify_wq**(struct ib_wq * wq, struct ib_wq_attr * wq_attr, u32 wq_attr_mask)
Modifies the specified WQ.

Parameters

struct ib_wq * wq The WQ to modify.

struct ib_wq_attr * wq_attr On input, specifies the WQ attributes to modify.

u32 wq_attr_mask A bit-mask used to specify which attributes of the WQ are being modified. On output, the current values of selected WQ attributes are returned.

int **ib_map_mr_sg_pi**(struct ib_mr * mr, struct scatterlist * data_sg, int data_sg_nents, unsigned int * data_sg_offset, struct scatterlist * meta_sg, int meta_sg_nents, unsigned int * meta_sg_offset, unsigned int page_size)
Map the dma mapped SG lists for PI (protection information) and set an appropriate memory region for registration.

Parameters

struct ib_mr * mr memory region

struct scatterlist * data_sg dma mapped scatterlist for data

int data_sg_nents number of entries in data_sg

unsigned int * data_sg_offset offset in bytes into data_sg

struct scatterlist * meta_sg dma mapped scatterlist for metadata

int meta_sg_nents number of entries in meta_sg

unsigned int * meta_sg_offset offset in bytes into meta_sg

unsigned int page_size page vector desired page size

Description

Constraints: - The MR must be allocated with type IB_MR_TYPE_INTEGRITY.

After this completes successfully, the memory region is ready for registration.

Return

0 on success.

int **ib_map_mr_sg**(struct ib_mr * mr, struct scatterlist * sg, int sg_nents, unsigned int * sg_offset, unsigned int page_size)
Map the largest prefix of a dma mapped SG list and set it the memory region.

Parameters

struct ib_mr * mr memory region

struct scatterlist * sg dma mapped scatterlist

int sg_nents number of entries in sg

unsigned int * sg_offset offset in bytes into sg

unsigned int page_size page vector desired page size

Description

Constraints:

- The first sg element is allowed to have an offset.
- Each sg element must either be aligned to page_size or virtually contiguous to the previous element. In case an sg element has a non-contiguous offset, the mapping prefix will not include it.
- The last sg element is allowed to have length less than page_size.
- If sg_nents total byte length exceeds the mr max_num_sge * page_size then only max_num_sg entries will be mapped.
- If the MR was allocated with type IB_MR_TYPE_SG_GAPS, none of these constraints holds and the page_size argument is ignored.

Returns the number of sg elements that were mapped to the memory region.

After this completes successfully, the memory region is ready for registration.

int **ib_sg_to_pages**(struct ib_mr * mr, struct scatterlist * sgl, int sg_nents, unsigned int * sg_offset_p, int (*set_page)(struct ib_mr *, u64))
Convert the largest prefix of a sg list to a page vector

Parameters

struct ib_mr * mr memory region

struct scatterlist * sgl dma mapped scatterlist

int sg_nents number of entries in sg

unsigned int * sg_offset_p

IN	start offset in bytes into sg
OUT	offset in bytes for element n of the sg of the first byte that has not been processed where n is the return value of this function.

int (*)(struct ib_mr *, u64) set_page driver page assignment function pointer

Description

Core service helper for drivers to convert the largest prefix of given sg list to a page vector. The sg list prefix converted is the prefix that meet the requirements of ib_map_mr_sg.

Returns the number of sg elements that were assigned to a page vector.

void **ib_drain_sq**(struct ib_qp * qp)
Block until all SQ CQEs have been consumed by the application.

Parameters

struct ib_qp * qp queue pair to drain

Description

If the device has a provider-specific drain function, then call that. Otherwise call the generic drain function __ib_drain_sq().

The caller must:

ensure there is room in the CQ and SQ for the drain work request and completion.

allocate the CQ using ib_alloc_cq().

ensure that there are no other contexts that are posting WRs concurrently. Otherwise the drain is not guaranteed.

void **ib_drain_rq**(struct ib_qp * qp)
Block until all RQ CQEs have been consumed by the application.

Parameters

struct ib_qp * qp queue pair to drain

Description

If the device has a provider-specific drain function, then call that. Otherwise call the generic drain function __ib_drain_rq().

The caller must:

ensure there is room in the CQ and RQ for the drain work request and completion.

allocate the CQ using ib_alloc_cq().

ensure that there are no other contexts that are posting WRs concurrently. Otherwise the drain is not guaranteed.

void **ib_drain_qp**(struct ib_qp * qp)
Block until all CQEs have been consumed by the application on both the RQ and SQ.

Parameters

struct ib_qp * qp queue pair to drain

Description

The caller must:

ensure there is room in the CQ(s), SQ, and RQ for drain work requests and completions.

allocate the CQs using ib_alloc_cq().

ensure that there are no other contexts that are posting WRs concurrently. Otherwise the drain is not guaranteed.

void **ib_pack**(const struct ib_field * desc, int desc_len, void * structure, void * buf)
Pack a structure into a buffer

Parameters

const struct ib_field * desc Array of structure field descriptions

int desc_len Number of entries in **desc**

void * structure Structure to pack from

void * buf Buffer to pack into

Description

ib_pack() packs a list of structure fields into a buffer, controlled by the array of fields in **desc**.

void **ib_unpack**(const struct ib_field * desc, int desc_len, void * buf, void * structure)
Unpack a buffer into a structure

Parameters

const struct ib_field * desc Array of structure field descriptions

int desc_len Number of entries in **desc**

void * buf Buffer to unpack from

void * structure Structure to unpack into

Description

ib_pack() unpacks a list of structure fields from a buffer, controlled by the array of fields in **desc**.

void **ib_sa_cancel_query**(int id, struct ib_sa_query * query)
try to cancel an SA query

Parameters

int id ID of query to cancel

struct ib_sa_query * query query pointer to cancel

Description

Try to cancel an SA query. If the id and query don't match up or the query has already completed, nothing is done. Otherwise the query is canceled and will complete with a status of -EINTR.

int **ib_init_ah_attr_from_path**(struct ib_device * device, u8 port_num, struct sa_path_rec * rec, struct rdma_ah_attr * ah_attr, const struct ib_gid_attr * gid_attr)
Initialize address handle attributes based on an SA path record.

Parameters

struct ib_device * device Device associated ah attributes initialization.

u8 port_num Port on the specified device.

struct sa_path_rec * rec path record entry to use for ah attributes initialization.

struct rdma_ah_attr * ah_attr address handle attributes to initialization from path record.

const struct ib_gid_attr * gid_attr SGID attribute to consider during initialization.

Description

When `ib_init_ah_attr_from_path()` returns success, (a) for IB link layer it optionally contains a reference to SGID attribute when GRH is present for IB link layer. (b) for RoCE link layer it contains a reference to SGID attribute. User must invoke `rdma_destroy_ah_attr()` to release reference to SGID attributes which are initialized using `ib_init_ah_attr_from_path()`.

int **ib_sa_path_rec_get**(struct ib_sa_client * client, struct ib_device * device, u8 port_num, struct sa_path_rec * rec, ib_sa_comp_mask comp_mask, unsigned long timeout_ms, gfp_t gfp_mask, void (*callback)(int status, struct sa_path_rec *resp, void *context), void * context, struct ib_sa_query ** sa_query)

Start a Path get query

Parameters

struct ib_sa_client * client SA client

struct ib_device * device device to send query on

u8 port_num port number to send query on

struct sa_path_rec * rec Path Record to send in query

ib_sa_comp_mask comp_mask component mask to send in query

unsigned long timeout_ms time to wait for response

gfp_t gfp_mask GFP mask to use for internal allocations

void (*)(int status, struct sa_path_rec *resp, void *context) callback function called when query completes, times out or is canceled

void * context opaque user context passed to callback

struct ib_sa_query ** sa_query query context, used to cancel query

Description

Send a Path Record Get query to the SA to look up a path. The callback function will be called when the query completes (or fails); status is 0 for a successful response, -EINTR if the query is canceled, -ETIMEDOUT is the query timed out, or -EIO if an error occurred sending the query. The resp parameter of the callback is only valid if status is 0.

If the return value of `ib_sa_path_rec_get()` is negative, it is an error code. Otherwise it is a query ID that can be used to cancel the query.

int **ib_sa_service_rec_query**(struct ib_sa_client * client, struct ib_device * device, u8 port_num, u8 method, struct ib_sa_service_rec * rec, ib_sa_comp_mask comp_mask, unsigned long timeout_ms, gfp_t gfp_mask, void (*callback)(int status, struct ib_sa_service_rec *resp, void *context), void * context, struct ib_sa_query ** sa_query)

Start Service Record operation

Parameters

struct ib_sa_client * client SA client

struct ib_device * device device to send request on

u8 port_num port number to send request on

u8 method SA method - should be get, set, or delete

struct ib_sa_service_rec * rec Service Record to send in request

ib_sa_comp_mask comp_mask component mask to send in request

unsigned long timeout_ms time to wait for response

gfp_t gfp_mask GFP mask to use for internal allocations

void (*)(int status, struct ib_sa_service_rec *resp, void *context) callback function called when request completes, times out or is canceled

void * context opaque user context passed to callback

struct ib_sa_query ** sa_query request context, used to cancel request

Description

Send a Service Record set/get/delete to the SA to register, unregister or query a service record. The callback function will be called when the request completes (or fails); status is 0 for a successful response, -EINTR if the query is canceled, -ETIMEDOUT is the query timed out, or -EIO if an error occurred sending the query. The resp parameter of the callback is only valid if status is 0.

If the return value of `ib_sa_service_rec_query()` is negative, it is an error code. Otherwise it is a request ID that can be used to cancel the query.

int **ib_ud_header_init**(int payload_bytes, int lrh_present, int eth_present, int vlan_present, int grh_present, int ip_version, int udp_present, int immediate_present, struct ib_ud_header * header)

Initialize UD header structure

Parameters

int payload_bytes Length of packet payload

int lrh_present specify if LRH is present

int eth_present specify if Eth header is present

int vlan_present packet is tagged vlan

int grh_present GRH flag (if non-zero, GRH will be included)

int ip_version if non-zero, IP header, V4 or V6, will be included

int udp_present if non-zero, UDP header will be included

int immediate_present specify if immediate data is present

struct ib_ud_header * header Structure to initialize

int **ib_ud_header_pack**(struct ib_ud_header * header, void * buf)
Pack UD header struct into wire format

Parameters

struct ib_ud_header * header UD header struct

void * buf Buffer to pack into

Description

`ib_ud_header_pack()` packs the UD header structure **header** into wire format in the buffer **buf**.

int **ib_ud_header_unpack**(void * buf, struct ib_ud_header * header)
Unpack UD header struct from wire format

Parameters

void * buf Buffer to pack into

struct ib_ud_header * header UD header struct

Description

`ib_ud_header_pack()` unpacks the UD header structure **header** from wire format in the buffer **buf**.

unsigned long **ib_umem_find_best_pgsz**(struct ib_umem * umem, unsigned long pgsz_bitmap, unsigned long virt)
Find best HW page size to use for this MR

Parameters

struct ib_umem * umem umem struct

unsigned long pgsz_bitmap bitmap of HW supported page sizes

unsigned long virt IOVA

Description

This helper is intended for HW that support multiple page sizes but can do only a single page size in an MR.

Returns 0 if the umem requires page sizes not supported by the driver to be mapped. Drivers always supporting PAGE_SIZE or smaller will never see a 0 result.

struct ib_umem * **ib_umem_get**(struct ib_device * device, unsigned long addr, size_t size, int access)
Pin and DMA map userspace memory.

Parameters

struct ib_device * device IB device to connect UMEM

unsigned long addr userspace virtual address to start at

size_t size length of region to pin

int access IB_ACCESS_xxx flags for memory being pinned

void **ib_umem_release**(struct ib_umem * umem)
release memory pinned with ib_umem_get

Parameters

struct ib_umem * umem umem struct to release

struct ib_umem_odp * **ib_umem_odp_alloc_implicit**(struct ib_device * device, int access)
Allocate a parent implicit ODP umem

Parameters

struct ib_device * device IB device to create UMEM

int access ib_reg_mr access flags

Description

Implicit ODP umems do not have a VA range and do not have any page lists. They exist only to hold the per_mm reference to help the driver create children umems.

struct ib_umem_odp * **ib_umem_odp_alloc_child**(struct ib_umem_odp * root, unsigned long addr, size_t size, const struct mmu_interval_notifier_ops * ops)
Allocate a child ODP umem under an implicit parent ODP umem

Parameters

struct ib_umem_odp * root The parent umem enclosing the child. This must be allocated using ib_alloc_implicit_odp_umem()

unsigned long addr The starting userspace VA

size_t size The length of the userspace VA

const struct mmu_interval_notifier_ops * ops undescribed

struct ib_umem_odp * **ib_umem_odp_get**(struct ib_device * device, unsigned long addr, size_t size, int access, const struct mmu_interval_notifier_ops * ops)
Create a umem_odp for a userspace va

Parameters

struct ib_device * device IB device struct to get UMEM

unsigned long addr userspace virtual address to start at

size_t size length of region to pin

int access IB_ACCESS_xxx flags for memory being pinned

const struct mmu_interval_notifier_ops * ops undescribed

Description

The driver should use when the access flags indicate ODP memory. It avoids pinning, instead, stores the mm for future page fault handling in conjunction with MMU notifiers.

int **ib_umem_odp_map_dma_pages**(struct ib_umem_odp * umem_odp, u64 user_virt, u64 bcnt, u64 access_mask, unsigned long current_seq)

Pin and DMA map userspace memory in an ODP MR.

Parameters

struct ib_umem_odp * umem_odp the umem to map and pin

u64 user_virt the address from which we need to map.

u64 bcnt the minimal number of bytes to pin and map. The mapping might be bigger due to alignment, and may also be smaller in case of an error pinning or mapping a page. The actual pages mapped is returned in the return value.

u64 access_mask bit mask of the requested access permissions for the given range.

unsigned long current_seq the MMU notifiers sequance value for synchronization with invalidations. the sequance number is read from umem_odp->notifiers_seq before calling this function

Description

Pins the range of pages passed in the argument, and maps them to DMA addresses. The DMA addresses of the mapped pages is updated in umem_odp->dma_list.

Returns the number of pages mapped in success, negative error code for failure. An -EAGAIN error code is returned when a concurrent mmu notifier prevents the function from completing its task. An -ENOENT error code indicates that userspace process is being terminated and mm was already destroyed.

14.3 RDMA Verbs transport library

int **rvt_fast_reg_mr**(struct rvt_qp * qp, struct ib_mr * ibmr, u32 key, int access)

fast register physical MR

Parameters

struct rvt_qp * qp the queue pair where the work request comes from

struct ib_mr * ibmr the memory region to be registered

u32 key updated key for this memory region

int access access flags for this memory region

Description

Returns 0 on success.

int **rvt_invalidate_rkey**(struct rvt_qp * qp, u32 rkey)
invalidate an MR rkey

Parameters

struct rvt_qp * qp queue pair associated with the invalidate op

u32 rkey rkey to invalidate

Description

Returns 0 on success.

int **rvt_lkey_ok**(struct rvt_lkey_table * rkt, struct rvt_pd * pd, struct rvt_sge * isge, struct rvt_sge * last_sge, struct ib_sge * sge, int acc)
check IB SGE for validity and initialize

Parameters

struct rvt_lkey_table * rkt table containing lkey to check SGE against

struct rvt_pd * pd protection domain

struct rvt_sge * isge outgoing internal SGE

struct rvt_sge * last_sge last outgoing SGE written

struct ib_sge * sge SGE to check

int acc access flags

Description

Check the IB SGE for validity and initialize our internal version of it.

Increments the reference count when a new sge is stored.

Return

0 if compressed, 1 if added , otherwise returns -errno.

int **rvt_rkey_ok**(struct rvt_qp * qp, struct rvt_sge * sge, u32 len, u64 vaddr, u32 rkey, int acc)
check the IB virtual address, length, and RKEY

Parameters

struct rvt_qp * qp qp for validation

struct rvt_sge * sge SGE state

u32 len length of data

u64 vaddr virtual address to place data

u32 rkey rkey to check

int acc access flags

Return

1 if successful, otherwise 0.

Description

increments the reference count upon success

__be32 **rvt_compute_aeth**(struct rvt_qp * qp)
compute the AETH (syndrome + MSN)

Parameters

struct rvt_qp * qp the queue pair to compute the AETH for

Description

Returns the AETH.

void **rvt_get_credit**(struct rvt_qp * qp, u32 aeth)
flush the send work queue of a QP

Parameters

struct rvt_qp * qp the qp who’s send work queue to flush

u32 aeth the Acknowledge Extended Transport Header

Description

The QP s_lock should be held.

u32 **rvt_restart_sge**(struct rvt_sge_state * ss, struct rvt_swqe * wqe,
u32 len)
rewind the sge state for a wqe

Parameters

struct rvt_sge_state * ss the sge state pointer

struct rvt_swqe * wqe the wqe to rewind

u32 len the data length from the start of the wqe in bytes

Description

Returns the remaining data length.

int **rvt_check_ah**(struct ib_device * ibdev, struct rdma_ah_attr * ah_attr)
validate the attributes of AH

Parameters

struct ib_device * ibdev the ib device

struct rdma_ah_attr * ah_attr the attributes of the AH

Description

If driver supports a more detailed check_ah function call back to it otherwise just check the basics.

Return

0 on success

struct rvt_dev_info * **rvt_alloc_device**(size_t size, int nports)
allocate rdi

Parameters

size_t size how big of a structure to allocate

int nports number of ports to allocate array slots for

Description

Use IB core device alloc to allocate space for the rdi which is assumed to be inside of the ib_device. Any extra space that drivers require should be included in size.

We also allocate a port array based on the number of ports.

Return

pointer to allocated rdi

void **rvt_dealloc_device**(struct rvt_dev_info * rdi)
deallocate rdi

Parameters

struct rvt_dev_info * rdi structure to free

Description

Free a structure allocated with `rvt_alloc_device()`

int **rvt_register_device**(struct rvt_dev_info * rdi)
register a driver

Parameters

struct rvt_dev_info * rdi main dev structure for all of rdmavt operations

Description

It is up to drivers to allocate the rdi and fill in the appropriate information.

Return

0 on success otherwise an errno.

void **rvt_unregister_device**(struct rvt_dev_info * rdi)
remove a driver

Parameters

struct rvt_dev_info * rdi rvt dev struct

int **rvt_init_port**(struct rvt_dev_info * rdi, struct rvt_ibport * port, int port_index, u16 * pkey_table)
init internal data for driver port

Parameters

struct rvt_dev_info * rdi rvt_dev_info struct

struct rvt_ibport * port rvt port

int port_index 0 based index of ports, different from IB core port num

u16 * pkey_table pkey_table for **port**

Description

Keep track of a list of ports. No need to have a detach port. They persist until the driver goes away.

Return

always 0

bool **rvt_cq_enter**(struct rvt_cq * cq, struct ib_wc * entry, bool solicited)
add a new entry to the completion queue

Parameters

struct rvt_cq * cq completion queue

struct ib_wc * entry work completion entry to add

bool solicited true if **entry** is solicited

Description

This may be called with qp->s_lock held.

Return

return true on success, else return false if cq is full.

int **rvt_error_qp**(struct rvt_qp * qp, enum ib_wc_status err)
put a QP into the error state

Parameters

struct rvt_qp * qp the QP to put into the error state

enum ib_wc_status err the receive completion error to signal if a RWQE is active

Description

Flushes both send and receive work queues.

Return

true if last WQE event should be generated. The QP r_lock and s_lock should be held and interrupts disabled. If we are already in error state, just return.

int **rvt_get_rwqe**(struct rvt_qp * qp, bool wr_id_only)
copy the next RWQE into the QP’ s RWQE

Parameters

struct rvt_qp * qp the QP

bool wr_id_only update qp->r_wr_id only, not qp->r_sge

Description

Return -1 if there is a local error, 0 if no RWQE is available, otherwise return 1.

Can be called from interrupt level.

void **rvt_comm_est**(struct rvt_qp * qp)
handle trap with QP established

Parameters

struct rvt_qp * qp the QP

void **rvt_add_rnr_timer**(struct rvt_qp * qp, u32 aeth)
add/start an rnr timer on the QP

Parameters

struct rvt_qp * qp the QP

u32 aeth aeth of RNR timeout, simulated aeth for loopback

void **rvt_stop_rc_timers**(struct rvt_qp * qp)
stop all timers

Parameters

struct rvt_qp * qp the QP stop any pending timers

void **rvt_del_timers_sync**(struct rvt_qp * qp)
wait for any timeout routines to exit

Parameters

struct rvt_qp * qp the QP

struct rvt_qp_iter * **rvt_qp_iter_init**(struct rvt_dev_info * rdi, u64 v, void (*cb)(struct rvt_qp *qp, u64 v))
initial for QP iteration

Parameters

struct rvt_dev_info * rdi rvt devinfo

u64 v u64 value

void (*)(struct rvt_qp *qp, u64 v) cb user-defined callback

Description

This returns an iterator suitable for iterating QPs in the system.

The **cb** is a user-defined callback and **v** is a 64-bit value passed to and relevant for processing in the **cb**. An example use case would be to alter QP processing based on criteria not part of the rvt_qp.

Use cases that require memory allocation to succeed must preallocate appropriately.

Return

a pointer to an rvt_qp_iter or NULL

int **rvt_qp_iter_next**(struct rvt_qp_iter * iter)
return the next QP in iter

Parameters

struct rvt_qp_iter * iter the iterator

Description

Fine grained QP iterator suitable for use with debugfs seq_file mechanisms.

Updates iter->qp with the current QP when the return value is 0.

Return

0 - iter->qp is valid 1 - no more QPs

void **rvt_qp_iter**(struct rvt_dev_info * rdi, u64 v, void (*cb)(struct rvt_qp *qp, u64 v))
iterate all QPs

Parameters

struct rvt_dev_info * rdi rvt devinfo

u64 v a 64-bit value

void (*)(struct rvt_qp *qp, u64 v) cb a callback

Description

This provides a way for iterating all QPs.

The **cb** is a user-defined callback and **v** is a 64-bit value passed to and relevant for processing in the cb. An example use case would be to alter QP processing based on criteria not part of the rvt_qp.

The code has an internal iterator to simplify non seq_file use cases.

void **rvt_copy_sge**(struct rvt_qp * qp, struct rvt_sge_state * ss, void * data, u32 length, bool release, bool copy_last)
copy data to SGE memory

Parameters

struct rvt_qp * qp associated QP

struct rvt_sge_state * ss the SGE state

void * data the data to copy

u32 length the length of the data

bool release boolean to release MR

bool copy_last do a separate copy of the last 8 bytes

void **rvt_ruc_loopback**(struct rvt_qp * sqp)
handle UC and RC loopback requests

Parameters

struct rvt_qp * sqp the sending QP

Description

This is called from rvt_do_send() to forward a WQE addressed to the same HFI Note that although we are single threaded due to the send engine, we still have to protect against post_send(). We don't have to worry about receive interrupts since this is a connected protocol and all packets will pass through here.

struct rvt_mcast * **rvt_mcast_find**(struct rvt_ibport * ibp, union ib_gid * mgid, u16 lid)
search the global table for the given multicast GID/LID

Parameters

struct rvt_ibport * ibp the IB port structure

union ib_gid * mgid the multicast GID to search for

u16 lid the multicast LID portion of the multicast address (host order)

NOTE

It is valid to have 1 MLID with multiple MGIDs. It is not valid to have 1 MGID with multiple MLIDs.

Description

The caller is responsible for decrementing the reference count if found.

Return

NULL if not found.

desc_cache kmem cache for tx dataout

int **iscsi_iser_pdu_alloc**(struct iscsi_task * task, uint8_t opcode)
allocate an iscsi-iser PDU

Parameters

struct iscsi_task * task iscsi task

uint8_t opcode iscsi command opcode

Description

Notes: This routine can't fail, just assign iscsi task hdr and max hdr size.

int **iser_initialize_task_headers**(struct iscsi_task * task, struct iser_tx_desc * tx_desc)
Initialize task headers

Parameters

struct iscsi_task * task iscsi task

struct iser_tx_desc * tx_desc iser tx descriptor

Notes

This routine may race with iser teardown flow for scsi error handling TMFs. So for TMF we should acquire the state mutex to avoid dereferencing the IB device which may have already been terminated.

int **iscsi_iser_task_init**(struct iscsi_task * task)
Initialize iscsi-iser task

Parameters

struct iscsi_task * task iscsi task

Description

Initialize the task for the scsi command or mgmt command.

Return

Returns zero on success or -ENOMEM when failing to init task headers (dma mapping error).

int **iscsi_iser_mtask_xmit**(struct iscsi_conn * conn, struct iscsi_task * task)
xmit management (immediate) task

Parameters

struct iscsi_conn * conn iscsi connection

struct iscsi_task * task task management task

Notes

The function can return -EAGAIN in which case caller must call it again later, or recover. '0' return code means successful xmit.

int **iscsi_iser_task_xmit**(struct iscsi_task * task)
xmit iscsi-iser task

Parameters

struct iscsi_task * task iscsi task

Return

zero on success or escalates $error on failure.

void **iscsi_iser_cleanup_task**(struct iscsi_task * task)
cleanup an iscsi-iser task

Parameters

struct iscsi_task * task iscsi task

Notes

In case the RDMA device is already NULL (might have been removed in DEVICE_REMOVAL CM event it will bail-out without doing dma unmapping.

u8 **iscsi_iser_check_protection**(struct iscsi_task * task, sector_t * sector)
check protection information status of task.

Parameters

struct iscsi_task * task iscsi task

sector_t * sector error sector if exsists (output)

Return

zero if no data-integrity errors have occured 0x1: data-integrity error occured in the guard-block 0x2: data-integrity error occured in the reference tag 0x3: data-integrity error occured in the application tag

In addition the error sector is marked.

struct iscsi_cls_conn * **iscsi_iser_conn_create**(struct iscsi_cls_session * cls_session, uint32_t conn_idx)
create a new iscsi-iser connection

Parameters

struct iscsi_cls_session * cls_session iscsi class connection

uint32_t conn_idx connection index within the session (for MCS)

Return

iscsi_cls_conn when iscsi_conn_setup succeeds or NULL otherwise.

int **iscsi_iser_conn_bind**(struct iscsi_cls_session * cls_session, struct iscsi_cls_conn * cls_conn, uint64_t transport_eph, int is_leading)
bind iscsi and iser connection structures

Parameters

struct iscsi_cls_session * cls_session iscsi class session

struct iscsi_cls_conn * cls_conn iscsi class connection

uint64_t transport_eph transport end-point handle

int is_leading indicate if this is the session leading connection (MCS)

Return

zero on success, $error if iscsi_conn_bind fails and -EINVAL in case end-point doesn't exsits anymore or iser connection state is not UP (teardown already started).

int **iscsi_iser_conn_start**(struct iscsi_cls_conn * cls_conn)
start iscsi-iser connection

Parameters

struct iscsi_cls_conn * cls_conn iscsi class connection

Notes

Here iser intialize (or re-initialize) stop_completion as from this point iscsi must call conn_stop in session/connection teardown so iser transport must wait for it.

void **iscsi_iser_conn_stop**(struct iscsi_cls_conn * cls_conn, int flag)
stop iscsi-iser connection

Parameters

struct iscsi_cls_conn * cls_conn iscsi class connection

int flag indicate if recover or terminate (passed as is)

Notes

Calling iscsi_conn_stop might theoretically race with DEVICE_REMOVAL event and dereference a previously freed RDMA device handle, so we call it under iser the state lock to protect against this kind of race.

void **iscsi_iser_session_destroy**(struct iscsi_cls_session * cls_session)
destroy iscsi-iser session

Parameters

struct iscsi_cls_session * cls_session iscsi class session

Description

Removes and free iscsi host.

struct iscsi_cls_session * **iscsi_iser_session_create**(struct iscsi_endpoint * ep, uint16_t cmds_max, uint16_t qdepth, uint32_t initial_cmdsn)

create an iscsi-iser session

Parameters

struct iscsi_endpoint * ep iscsi end-point handle

uint16_t cmds_max maximum commands in this session

uint16_t qdepth session command queue depth

uint32_t initial_cmdsn initiator command sequnce number

Description

Allocates and adds a scsi host, expose DIF supprot if exists, and sets up an iscsi session.

struct iscsi_endpoint * **iscsi_iser_ep_connect**(struct Scsi_Host * shost, struct sockaddr * dst_addr, int non_blocking)

Initiate iSER connection establishment

Parameters

struct Scsi_Host * shost scsi_host

struct sockaddr * dst_addr destination address

int non_blocking indicate if routine can block

Description

Allocate an iscsi endpoint, an iser_conn structure and bind them. After that start RDMA connection establishment via rdma_cm. We don't allocate iser_conn embedded in iscsi_endpoint since in teardown the endpoint will be destroyed at ep_disconnect while iser_conn will cleanup its resources asynchronuously.

Return

iscsi_endpoint created by iscsi layer or ERR_PTR(error) if fails.

int **iscsi_iser_ep_poll**(struct iscsi_endpoint * ep, int timeout_ms)

poll for iser connection establishment to complete

Parameters

struct iscsi_endpoint * ep iscsi endpoint (created at ep_connect)

int timeout_ms polling timeout allowed in ms.

Description

This routine boils down to waiting for up_completion signaling that cma_id got CONNECTED event.

Return

1 if succeeded in connection establishment, 0 if timeout expired (libiscsi will retry will kick in) or -1 if interrupted by signal or more likely iser connection state transitioned to TEMINATING or DOWN during the wait period.

void **iscsi_iser_ep_disconnect**(struct iscsi_endpoint * ep)
Initiate connection teardown process

Parameters

struct iscsi_endpoint * ep iscsi endpoint handle

Description

This routine is not blocked by iser and RDMA termination process completion as we queue a deffered work for iser/RDMA destruction and cleanup or actually call it immediately in case we didn't pass iscsi conn bind/start stage, thus it is safe.

int **iser_send_command**(struct iscsi_conn * conn, struct iscsi_task * task)
send command PDU

Parameters

struct iscsi_conn * conn link to matching iscsi connection

struct iscsi_task * task SCSI command task

int **iser_send_data_out**(struct iscsi_conn * conn, struct iscsi_task * task, struct iscsi_data * hdr)
send data out PDU

Parameters

struct iscsi_conn * conn link to matching iscsi connection

struct iscsi_task * task SCSI command task

struct iscsi_data * hdr pointer to the LLD's iSCSI message header

int **iser_alloc_fastreg_pool**(struct ib_conn * ib_conn, unsigned cmds_max, unsigned int size)
Creates pool of fast_reg descriptors for fast registration work requests.

Parameters

struct ib_conn * ib_conn connection RDMA resources

unsigned cmds_max max number of SCSI commands for this connection

unsigned int size max number of pages per map request

Return

0 on success, or errno code on failure

void **iser_free_fastreg_pool**(struct ib_conn * ib_conn)
releases the pool of fast_reg descriptors

Parameters

struct ib_conn * ib_conn connection RDMA resources

void **iser_free_ib_conn_res**(struct iser_conn * iser_conn, bool destroy)
release IB related resources

Parameters

struct iser_conn * iser_conn iser connection struct

bool destroy indicator if we need to try to release the iser device and memory regoins pool (only iscsi shutdown and DEVICE_REMOVAL will use this).

Description

This routine is called with the iser state mutex held so the cm_id removal is out of here. It is Safe to be invoked multiple times.

void **iser_conn_release**(struct iser_conn * iser_conn)
Frees all conn objects and deallocs conn descriptor

Parameters

struct iser_conn * iser_conn iSER connection context

int **iser_conn_terminate**(struct iser_conn * iser_conn)
triggers start of the disconnect procedures and waits for them to be done

Parameters

struct iser_conn * iser_conn iSER connection context

Description

Called with state mutex held

int **iser_post_send**(struct ib_conn * ib_conn, struct iser_tx_desc * tx_desc, bool signal)
Initiate a Send DTO operation

Parameters

struct ib_conn * ib_conn connection RDMA resources

struct iser_tx_desc * tx_desc iSER TX descriptor

bool signal true to send work request as SIGNALED

Return

0 on success, -1 on failure

14.4.2 Omni-Path (OPA) Virtual NIC support

struct **opa_veswport_info**
OPA vnic port information

Definition

```
struct opa_veswport_info {
  struct opa_vesw_info          vesw;
  struct opa_per_veswport_info  vport;
};
```

Members

vesw OPA vnic switch information

vport OPA vnic per port information

Description

On host, each of the virtual ethernet ports belongs to a different virtual ethernet switches.

struct **opa_veswport_mactable_entry**
single entry in the forwarding table

Definition

```
struct opa_veswport_mactable_entry {
  u8 mac_addr[ETH_ALEN];
  u8 mac_addr_mask[ETH_ALEN];
  __be32 dlid_sd;
};
```

Members

mac_addr MAC address

mac_addr_mask MAC address bit mask

dlid_sd Matching DLID and side data

Description

On the host each virtual ethernet port will have a forwarding table. These tables are used to map a MAC to a LID and other data. For more details see struct opa_veswport_mactable_entries. This is the structure of a single mactable entry

struct **opa_veswport_mactable**
Forwarding table array

Definition

```
struct opa_veswport_mactable {
  __be16 offset;
  __be16 num_entries;
  __be32 mac_tbl_digest;
  struct opa_veswport_mactable_entry  tbl_entries[];
};
```

Members

offset mac table starting offset

num_entries Number of entries to get or set

mac_tbl_digest mac table digest

tbl_entries Array of table entries

Description

The EM sends down this structure in a MAD indicating the starting offset in the forwarding table that this entry is to be loaded into and the number of entries that that this MAD instance contains The mac_tbl_digest has been added to this MAD structure. It will be set by the EM and it will be used by the EM to check if there are any discrepancies with this value and the value maintained by the EM in the case of VNIC port being deleted or unloaded A new instantiation of a VNIC will always have a value of zero. This value is stored as part of the vnic adapter structure and will be accessed by the GET and SET routines for both the mactable entries and the veswport info.

struct **opa_veswport_trap**
Trap message sent to EM by VNIC

Definition

```
struct opa_veswport_trap {
  __be16 fabric_id;
  __be16 veswid;
  __be32 veswportnum;
  __be16 opaportnum;
  u8 veswportindex;
  u8 opcode;
  __be32 reserved;
};
```

Members

fabric_id 10 bit fabric id

veswid 12 bit virtual ethernet switch id

veswportnum logical port number on the Virtual switch

opaportnum physical port num (redundant on host)

veswportindex switch port index on opa port 0 based

opcode operation

reserved 32 bit for alignment

Description

The VNIC will send trap messages to the Ethernet manager to inform it about changes to the VNIC config, behaviour etc. This is the format of the trap payload.

struct **opa_vnic_iface_mac_entry**
single entry in the mac list

Definition

```
struct opa_vnic_iface_mac_entry {

void **opa_vnic_vema_report_event**(struct opa_vnic_adapter * adapter, u8 event)
sent trap to report the specified event

Parameters

struct opa_vnic_adapter * adapter vnic port adapter

u8 event event to be reported

Description

This function calls vema api to sent a trap for the given event.

void **opa_vnic_get_summary_counters**(struct opa_vnic_adapter * adapter, struct opa_veswport_summary_counters * cntrs)
get summary counters

Parameters

struct opa_vnic_adapter * adapter vnic port adapter

struct opa_veswport_summary_counters * cntrs pointer to destination summary counters structure

Description

This function populates the summary counters that is maintained by the given adapter to destination address provided.

void **opa_vnic_get_error_counters**(struct opa_vnic_adapter * adapter, struct opa_veswport_error_counters * cntrs)
get error counters

Parameters

struct opa_vnic_adapter * adapter vnic port adapter

struct opa_veswport_error_counters * cntrs pointer to destination error counters structure

Description

This function populates the error counters that is maintained by the given adapter to destination address provided.

void **opa_vnic_get_vesw_info**(struct opa_vnic_adapter * adapter, struct opa_vesw_info * info)

- Get the vesw information

Parameters

struct opa_vnic_adapter * adapter vnic port adapter

struct opa_vesw_info * info pointer to destination vesw info structure

Description

This function copies the vesw info that is maintained by the given adapter to destination address provided.

void **opa_vnic_set_vesw_info**(struct opa_vnic_adapter * adapter, struct opa_vesw_info * info)

- Set the vesw information

Parameters

struct opa_vnic_adapter * adapter vnic port adapter

struct opa_vesw_info * info pointer to vesw info structure

Description

This function updates the vesw info that is maintained by the given adapter with vesw info provided. Reserved fields are stored and returned back to EM as is.

void **opa_vnic_get_per_veswport_info**(struct opa_vnic_adapter * adapter, struct opa_per_veswport_info * info)

- Get the vesw per port information

Parameters

struct opa_vnic_adapter * adapter vnic port adapter

struct opa_per_veswport_info * info pointer to destination vport info structure

Description

This function copies the vesw per port info that is maintained by the given adapter to destination address provided. Note that the read only fields are not copied.

void **opa_vnic_set_per_veswport_info**(struct opa_vnic_adapter * adapter, struct opa_per_veswport_info * info)

- Set vesw per port information

Parameters

struct opa_vnic_adapter * adapter vnic port adapter

struct opa_per_veswport_info * info pointer to vport info structure

Description

This function updates the vesw per port info that is maintained by the given adapter with vesw per port info provided. Reserved fields are stored and returned back to EM as is.

void **opa_vnic_query_mcast_macs**(struct opa_vnic_adapter * adapter, struct opa_veswport_iface_macs * macs)

query multicast mac list

Parameters

struct opa_vnic_adapter * adapter vnic port adapter

struct opa_veswport_iface_macs * macs pointer mac list

Description

This function populates the provided mac list with the configured multicast addresses in the adapter.

void **opa_vnic_query_ucast_macs**(struct opa_vnic_adapter * adapter, struct opa_veswport_iface_macs * macs)

query unicast mac list

Parameters

struct opa_vnic_adapter * adapter vnic port adapter

struct opa_veswport_iface_macs * macs pointer mac list

Description

This function populates the provided mac list with the configured unicast addresses in the adapter.

struct **opa_vnic_vema_port**

- VNIC VEMA port details

Definition

```
struct opa_vnic_vema_port {
  struct opa_vnic_ctrl_port      *cport;

  u64 tid;
  u8 port_num;
  struct xarray                   vports;
  struct ib_event_handler         event_handler;
  struct mutex                    lock;
};
```

Members

cport pointer to port

mad_agent pointer to mad agent for port

class_port_info Class port info information.

tid Transaction id

port_num OPA port number

vports vnic ports

event_handler ib event handler

lock adapter interface lock

u8 **vema_get_vport_num**(struct opa_vnic_vema_mad * recvd_mad)

- Get the vnic from the mad

Parameters

struct opa_vnic_vema_mad * recvd_mad Received mad

Return

returns value of the vnic port number

struct opa_vnic_adapter * **vema_get_vport_adapter**(struct opa_vnic_vema_mad * recvd_mad, struct opa_vnic_vema_port * port)

- Get vnic port adapter from recvd mad

Parameters

struct opa_vnic_vema_mad * recvd_mad received mad

struct opa_vnic_vema_port * port ptr to port struct on which MAD was recvd

Return

vnic adapter

bool **vema_mac_tbl_req_ok**(struct opa_veswport_mactable * mac_tbl)

- Check if mac request has correct values

Parameters

struct opa_veswport_mactable * mac_tbl mac table

Description

This function checks for the validity of the offset and number of entries required.

Return

true if offset and num_entries are valid

struct opa_vnic_adapter * **vema_add_vport**(struct opa_vnic_vema_port * port, u8 vport_num)

- Add a new vnic port

Parameters

struct opa_vnic_vema_port * port ptr to opa_vnic_vema_port struct

u8 vport_num vnic port number (to be added)

Description

Return a pointer to the vnic adapter structure

void **vema_get_class_port_info**(struct opa_vnic_vema_port * port, struct opa_vnic_vema_mad * recvd_mad, struct opa_vnic_vema_mad * rsp_mad)

- Get class info for port

Parameters

struct opa_vnic_vema_port * port Port on whic MAD was received

struct opa_vnic_vema_mad * recvd_mad pointer to the received mad

struct opa_vnic_vema_mad * rsp_mad pointer to respose mad

Description

This function copies the latest class port info value set for the port and stores it for generating traps

void **vema_set_class_port_info**(struct opa_vnic_vema_port * port, struct opa_vnic_vema_mad * recvd_mad, struct opa_vnic_vema_mad * rsp_mad)

- Get class info for port

Parameters

struct opa_vnic_vema_port * port Port on whic MAD was received

struct opa_vnic_vema_mad * recvd_mad pointer to the received mad

struct opa_vnic_vema_mad * rsp_mad pointer to respose mad

Description

This function updates the port class info for the specific vnic and sets up the response mad data

void **vema_get_veswport_info**(struct opa_vnic_vema_port * port, struct opa_vnic_vema_mad * recvd_mad, struct opa_vnic_vema_mad * rsp_mad)

- Get veswport info

Parameters

struct opa_vnic_vema_port * port source port on which MAD was received

struct opa_vnic_vema_mad * recvd_mad pointer to the received mad

struct opa_vnic_vema_mad * rsp_mad pointer to respose mad

void **vema_set_veswport_info**(struct opa_vnic_vema_port * port, struct opa_vnic_vema_mad * recvd_mad, struct opa_vnic_vema_mad * rsp_mad)

- Set veswport info

Parameters

struct opa_vnic_vema_port * port source port on which MAD was received

struct opa_vnic_vema_mad * recvd_mad pointer to the received mad

struct opa_vnic_vema_mad * rsp_mad pointer to respose mad

Description

This function gets the port class infor for vnic

void **vema_get_mac_entries**(struct opa_vnic_vema_port * port, struct opa_vnic_vema_mad * recvd_mad, struct opa_vnic_vema_mad * rsp_mad)

- Get MAC entries in VNIC MAC table

Parameters

struct opa_vnic_vema_port * port source port on which MAD was received

struct opa_vnic_vema_mad * recvd_mad pointer to the received mad

struct opa_vnic_vema_mad * rsp_mad pointer to respose mad

Description

This function gets the MAC entries that are programmed into the VNIC MAC forwarding table. It checks for the validity of the index into the MAC table and the number of entries that are to be retrieved.

void **vema_set_mac_entries**(struct opa_vnic_vema_port * port, struct opa_vnic_vema_mad * recvd_mad, struct opa_vnic_vema_mad * rsp_mad)

- Set MAC entries in VNIC MAC table

Parameters

struct opa_vnic_vema_port * port source port on which MAD was received

struct opa_vnic_vema_mad * recvd_mad pointer to the received mad

struct opa_vnic_vema_mad * rsp_mad pointer to respose mad

Description

This function sets the MAC entries in the VNIC forwarding table It checks for the validity of the index and the number of forwarding table entries to be programmed.

void **vema_set_delete_vesw**(struct opa_vnic_vema_port * port, struct opa_vnic_vema_mad * recvd_mad, struct opa_vnic_vema_mad * rsp_mad)

- Reset VESW info to POD values

Parameters

struct opa_vnic_vema_port * port source port on which MAD was received

struct opa_vnic_vema_mad * recvd_mad pointer to the received mad

struct opa_vnic_vema_mad * rsp_mad pointer to respose mad

Description

This function clears all the fields of veswport info for the requested vesw and sets them back to the power-on default values. It does not delete the vesw.

void **vema_get_mac_list**(struct opa_vnic_vema_port * port, struct opa_vnic_vema_mad * recvd_mad, struct opa_vnic_vema_mad * rsp_mad, u16 attr_id)

- Get the unicast/multicast macs.

Parameters

struct opa_vnic_vema_port * port source port on which MAD was received

struct opa_vnic_vema_mad * recvd_mad Received mad contains fields to set vnic parameters

struct opa_vnic_vema_mad * rsp_mad Response mad to be built

u16 attr_id Attribute ID indicating multicast or unicast mac list

void **vema_get_summary_counters**(struct opa_vnic_vema_port * port, struct opa_vnic_vema_mad * recvd_mad, struct opa_vnic_vema_mad * rsp_mad)

- Gets summary counters.

Parameters

struct opa_vnic_vema_port * port source port on which MAD was received

struct opa_vnic_vema_mad * recvd_mad Received mad contains fields to set vnic parameters

struct opa_vnic_vema_mad * rsp_mad Response mad to be built

void **vema_get_error_counters**(struct opa_vnic_vema_port * port, struct opa_vnic_vema_mad * recvd_mad, struct opa_vnic_vema_mad * rsp_mad)

- Gets summary counters.

Parameters

struct opa_vnic_vema_port * port source port on which MAD was received

struct opa_vnic_vema_mad * recvd_mad Received mad contains fields to set vnic parameters

struct opa_vnic_vema_mad * rsp_mad Response mad to be built

void **vema_get**(struct opa_vnic_vema_port * port, struct opa_vnic_vema_mad * recvd_mad, struct opa_vnic_vema_mad * rsp_mad)

- Process received get MAD

Parameters

struct opa_vnic_vema_port * port source port on which MAD was received

struct opa_vnic_vema_mad * recvd_mad Received mad

struct opa_vnic_vema_mad * rsp_mad Response mad to be built

void **vema_set**(struct opa_vnic_vema_port * port, struct opa_vnic_vema_mad * recvd_mad, struct opa_vnic_vema_mad * rsp_mad)

- Process received set MAD

Parameters

struct opa_vnic_vema_port * port source port on which MAD was received

struct opa_vnic_vema_mad * recvd_mad Received mad contains fields to set vnic parameters

struct opa_vnic_vema_mad * rsp_mad Response mad to be built

void **vema_send**(struct ib_mad_agent * mad_agent, struct ib_mad_send_wc * mad_wc)

- Send handler for VEMA MAD agent

Parameters

struct ib_mad_agent * mad_agent pointer to the mad agent

struct ib_mad_send_wc * mad_wc pointer to mad send work completion information

Description

Free all the data structures associated with the sent MAD

void **vema_recv**(struct ib_mad_agent * mad_agent, struct ib_mad_send_buf * send_buf, struct ib_mad_recv_wc * mad_wc)

- Recv handler for VEMA MAD agent

Parameters

struct ib_mad_agent * mad_agent pointer to the mad agent

struct ib_mad_send_buf * send_buf Send buffer if found, else NULL

struct ib_mad_recv_wc * mad_wc pointer to mad send work completion information

Description

Handle only set and get methods and respond to other methods as unsupported. Allocate response buffer and address handle for the response MAD.

struct opa_vnic_vema_port * **vema_get_port**(struct opa_vnic_ctrl_port * cport, u8 port_num)

- Gets the opa_vnic_vema_port

Parameters

struct opa_vnic_ctrl_port * cport pointer to control dev

u8 port_num Port number

Description

This function loops through the ports and returns the opa_vnic_vema port structure that is associated with the OPA port number

Return

ptr to requested opa_vnic_vema_port strucure if success, NULL if not

void **opa_vnic_vema_send_trap**(struct opa_vnic_adapter * adapter, struct __opa_veswport_trap * data, u32 lid)

- This function sends a trap to the EM

Parameters

struct opa_vnic_adapter * adapter pointer to vnic adapter

struct __opa_veswport_trap * data pointer to trap data filled by calling function

u32 lid issuers lid (encap_slid from vesw_port_info)

Description

This function is called from the VNIC driver to send a trap if there is somethng the EM should be notified about. These events currently are 1) UNICAST INTERFACE MACADDRESS changes 2) MULTICAST INTERFACE MACADDRESS changes 3) ETHERNET LINK STATUS changes While allocating the send mad the remote site qpn used is 1 as this is the well known QP.

void **vema_unregister**(struct opa_vnic_ctrl_port * cport)

- Unregisters agent

Parameters

struct opa_vnic_ctrl_port * cport pointer to control port

Description

This deletes the registration by VEMA for MADs

int **vema_register**(struct opa_vnic_ctrl_port * cport)

- Registers agent

Parameters

struct opa_vnic_ctrl_port * cport pointer to control port

Description

This function registers the handlers for the VEMA MADs

Return

returns 0 on success. non zero otherwise

void **opa_vnic_ctrl_config_dev**(struct opa_vnic_ctrl_port * cport, bool en)

- This function sends a trap to the EM by way of ib_modify_port to indicate support for ethernet on the fabric.

Parameters

struct opa_vnic_ctrl_port * cport pointer to control port

bool en enable or disable ethernet on fabric support

int **opa_vnic_vema_add_one**(struct ib_device * device)

- Handle new ib device

Parameters

struct ib_device * device ib device pointer

Description

Allocate the vnic control port and initialize it.

void **opa_vnic_vema_rem_one**(struct ib_device * device, void * client_data)

- Handle ib device removal

Parameters

struct ib_device * device ib device pointer

void * client_data ib client data

Description

Uninitialize and free the vnic control port.

14.4.3 InfiniBand SCSI RDMA protocol target support

enum **srpt_command_state**
SCSI command state managed by SRPT

Constants

SRPT_STATE_NEW New command arrived and is being processed.

SRPT_STATE_NEED_DATA Processing a write or bidir command and waiting for data arrival.

SRPT_STATE_DATA_IN Data for the write or bidir command arrived and is being processed.

SRPT_STATE_CMD_RSP_SENT SRP_RSP for SRP_CMD has been sent.

SRPT_STATE_MGMT Processing a SCSI task management command.

SRPT_STATE_MGMT_RSP_SENT SRP_RSP for SRP_TSK_MGMT has been sent.

SRPT_STATE_DONE Command processing finished successfully, command processing has been aborted or command processing failed.

struct **srpt_ioctx**
shared SRPT I/O context information

Definition

```
struct srpt_ioctx {
  struct ib_cqe           cqe;
  void *buf;
  dma_addr_t dma;
  uint32_t offset;
  uint32_t index;
};
```

Members

cqe Completion queue element.

buf Pointer to the buffer.

dma DMA address of the buffer.

offset Offset of the first byte in **buf** and **dma** that is actually used.

index Index of the I/O context in its ioctx_ring array.

struct **srpt_recv_ioctx**
SRPT receive I/O context

Definition

```
struct srpt_recv_ioctx {
  struct srpt_ioctx       ioctx;
  struct list_head        wait_list;
  int byte_len;
};
```

Members

ioctx See above.

wait_list Node for insertion in srpt_rdma_ch.cmd_wait_list.

byte_len Number of bytes in **ioctx.buf**.

struct **srpt_send_ioctx**
SRPT send I/O context

Definition

```
struct srpt_send_ioctx {
  struct srpt_ioctx       ioctx;
  struct srpt_rdma_ch     *ch;
  struct srpt_recv_ioctx  *recv_ioctx;
  struct srpt_rw_ctx      s_rw_ctx;
  struct srpt_rw_ctx      *rw_ctxs;
  struct scatterlist      imm_sg;
  struct ib_cqe           rdma_cqe;
  enum srpt_command_state state;
  struct se_cmd           cmd;
  u8 n_rdma;
  u8 n_rw_ctx;
  bool queue_status_only;
  u8 sense_data[TRANSPORT_SENSE_BUFFER];
};
```

Members

ioctx See above.

ch Channel pointer.

recv_ioctx Receive I/O context associated with this send I/O context. Only used for processing immediate data.

s_rw_ctx **rw_ctxs** points here if only a single rw_ctx is needed.

rw_ctxs RDMA read/write contexts.

imm_sg Scatterlist for immediate data.

rdma_cqe RDMA completion queue element.

state I/O context state.

cmd Target core command data structure.

n_rdma Number of work requests needed to transfer this ioctx.

n_rw_ctx Size of rw_ctxs array.

queue_status_only Send a SCSI status back to the initiator but no data.

sense_data Sense data to be sent to the initiator.

enum **rdma_ch_state**
SRP channel state

Constants

CH_CONNECTING QP is in RTR state; waiting for RTU.

CH_LIVE QP is in RTS state.

CH_DISCONNECTING DREQ has been sent and waiting for DREP or DREQ has been received.

CH_DRAINING DREP has been received or waiting for DREP timed out and last work request has been queued.

CH_DISCONNECTED Last completion has been received.

struct **srpt_rdma_ch**
RDMA channel

Definition

```
struct srpt_rdma_ch {
  struct srpt_nexus       *nexus;
  struct ib_qp            *qp;
  union {
    struct {
      struct ib_cm_id         *cm_id;
    } ib_cm;
    struct {
      struct rdma_cm_id       *cm_id;
    } rdma_cm;
  };
  struct ib_cq            *cq;
  struct ib_cqe           zw_cqe;
  struct rcu_head         rcu;
  struct kref             kref;
  struct completion       *closed;
  int rq_size;
  u32 max_rsp_size;
  atomic_t sq_wr_avail;
  struct srpt_port        *sport;
  int max_ti_iu_len;
  atomic_t req_lim;
  atomic_t req_lim_delta;
  u16 imm_data_offset;
  spinlock_t spinlock;
  enum rdma_ch_state      state;
  struct kmem_cache       *rsp_buf_cache;
  struct srpt_send_ioctx  **ioctx_ring;
  struct kmem_cache       *req_buf_cache;
  struct srpt_recv_ioctx  **ioctx_recv_ring;
  struct list_head        list;
  struct list_head        cmd_wait_list;
  uint16_t pkey;
  bool using_rdma_cm;
  bool processing_wait_list;
  struct se_session       *sess;
  u8 sess_name[40];
  struct work_struct      release_work;
};
```

Members

nexus I_T nexus this channel is associated with.

qp IB queue pair used for communicating over this channel.

{unnamed_union} anonymous

ib_cm See below.

ib_cm.cm_id IB CM ID associated with the channel.

rdma_cm See below.

rdma_cm.cm_id RDMA CM ID associated with the channel.

cq IB completion queue for this channel.

zw_cqe Zero-length write CQE.

rcu RCU head.

kref kref for this channel.

closed Completion object that will be signaled as soon as a new channel object with the same identity can be created.

rq_size IB receive queue size.

max_rsp_size Maximum size of an RSP response message in bytes.

sq_wr_avail number of work requests available in the send queue.

sport pointer to the information of the HCA port used by this channel.

max_ti_iu_len maximum target-to-initiator information unit length.

req_lim request limit: maximum number of requests that may be sent by the initiator without having received a response.

req_lim_delta Number of credits not yet sent back to the initiator.

imm_data_offset Offset from start of SRP_CMD for immediate data.

spinlock Protects free_list and state.

state channel state. See also enum rdma_ch_state.

rsp_buf_cache kmem_cache for **ioctx_ring**.

ioctx_ring Send ring.

req_buf_cache kmem_cache for **ioctx_recv_ring**.

ioctx_recv_ring Receive I/O context ring.

list Node in srpt_nexus.ch_list.

cmd_wait_list List of SCSI commands that arrived before the RTU event. This list contains struct srpt_ioctx elements and is protected against concurrent modification by the cm_id spinlock.

pkey P_Key of the IB partition for this SRP channel.

using_rdma_cm Whether the RDMA/CM or IB/CM is used for this channel.

processing_wait_list Whether or not cmd_wait_list is being processed.

sess Session information associated with this SRP channel.

sess_name Session name.

release_work Allows scheduling of srpt_release_channel().

struct **srpt_nexus**
I_T nexus

Definition

```
struct srpt_nexus {
  struct rcu_head         rcu;
  struct list_head        entry;
  struct list_head        ch_list;
  u8 i_port_id[16];
  u8 t_port_id[16];
};
```

Members

rcu RCU head for this data structure.

entry srpt_port.nexus_list list node.

ch_list struct srpt_rdma_ch list. Protected by srpt_port.mutex.

i_port_id 128-bit initiator port identifier copied from SRP_LOGIN_REQ.

t_port_id 128-bit target port identifier copied from SRP_LOGIN_REQ.

struct **srpt_port_attrib**
attributes for SRPT port

Definition

```
struct srpt_port_attrib {
  u32 srp_max_rdma_size;
  u32 srp_max_rsp_size;
  u32 srp_sq_size;
  bool use_srq;
};
```

Members

srp_max_rdma_size Maximum size of SRP RDMA transfers for new connections.

srp_max_rsp_size Maximum size of SRP response messages in bytes.

srp_sq_size Shared receive queue (SRQ) size.

use_srq Whether or not to use SRQ.

struct **srpt_tpg**
information about a single “target portal group”

Definition

```
struct srpt_tpg {
  struct list_head        entry;
  struct srpt_port_id     *sport_id;
  struct se_portal_group  tpg;
};
```

Members

entry Entry in **sport_id->tpg_list**.

sport_id Port name this TPG is associated with.

tpg LIO TPG data structure.

Description

Zero or more target portal groups are associated with each port name (srpt_port_id). With each TPG an ACL list is associated.

struct **srpt_port_id**
information about an RDMA port name

Definition

```
struct srpt_port_id {
  struct mutex            mutex;
  struct list_head        tpg_list;
  struct se_wwn           wwn;
  char name[64];
};
```

Members

mutex Protects **tpg_list** changes.

tpg_list TPGs associated with the RDMA port name.

wwn WWN associated with the RDMA port name.

name ASCII representation of the port name.

Description

Multiple sysfs directories can be associated with a single RDMA port. This data structure represents a single (port, name) pair.

struct **srpt_port**
information associated by SRPT with a single IB port

Definition

```
struct srpt_port {
  struct srpt_device      *sdev;
  struct ib_mad_agent     *mad_agent;
  bool enabled;
  u8 port;
  u32 sm_lid;
  u32 lid;
  union ib_gid            gid;
  struct work_struct      work;
  struct srpt_port_id     port_guid_id;
  struct srpt_port_id     port_gid_id;
  struct srpt_port_attrib port_attrib;
  atomic_t refcount;
  struct completion       *freed_channels;
  struct mutex            mutex;
  struct list_head        nexus_list;
};
```

Members

sdev backpointer to the HCA information.

mad_agent per-port management datagram processing information.

enabled Whether or not this target port is enabled.

port one-based port number.

sm_lid cached value of the port's sm_lid.

lid cached value of the port's lid.

gid cached value of the port's gid.

work work structure for refreshing the aforementioned cached values.

port_guid_id target port GUID

port_gid_id target port GID

port_attrib Port attributes that can be accessed through configfs.

refcount Number of objects associated with this port.

freed_channels Completion that will be signaled once **refcount** becomes 0.

mutex Protects nexus_list.

nexus_list Nexus list. See also srpt_nexus.entry.

struct **srpt_device**
information associated by SRPT with a single HCA

Definition

```
struct srpt_device {
  struct ib_device        *device;
  struct ib_pd            *pd;
  u32 lkey;
  struct ib_srq           *srq;
  struct ib_cm_id         *cm_id;
  int srq_size;
  struct mutex            sdev_mutex;
  bool use_srq;
  struct kmem_cache       *req_buf_cache;
  struct srpt_recv_ioctx  **ioctx_ring;
  struct ib_event_handler event_handler;
  struct list_head        list;
  struct srpt_port        port[];
};
```

Members

device Backpointer to the struct ib_device managed by the IB core.

pd IB protection domain.

lkey L_Key (local key) with write access to all local memory.

srq Per-HCA SRQ (shared receive queue).

cm_id Connection identifier.

srq_size SRQ size.

sdev_mutex Serializes use_srq changes.

use_srq Whether or not to use SRQ.

req_buf_cache kmem_cache for **ioctx_ring** buffers.

ioctx_ring Per-HCA SRQ.

event_handler Per-HCA asynchronous IB event handler.

list Node in srpt_dev_list.

port Information about the ports owned by this HCA.

void **srpt_event_handler**(struct ib_event_handler * handler, struct ib_event * event)
asynchronous IB event callback function

Parameters

struct ib_event_handler * handler IB event handler registered by `ib_register_event_handler()`.

struct ib_event * event Description of the event that occurred.

Description

Callback function called by the InfiniBand core when an asynchronous IB event occurs. This callback may occur in interrupt context. See also section 11.5.2, Set Asynchronous Event Handler in the InfiniBand Architecture Specification.

void **srpt_srq_event**(struct ib_event * event, void * ctx)
SRQ event callback function

Parameters

struct ib_event * event Description of the event that occurred.

void * ctx Context pointer specified at SRQ creation time.

void **srpt_qp_event**(struct ib_event * event, struct srpt_rdma_ch * ch)
QP event callback function

Parameters

struct ib_event * event Description of the event that occurred.

struct srpt_rdma_ch * ch SRPT RDMA channel.

void **srpt_set_ioc**(u8 * c_list, u32 slot, u8 value)
initialize a IOUnitInfo structure

Parameters

u8 * c_list controller list.

u32 slot one-based slot number.

u8 value four-bit value.

Description

Copies the lowest four bits of value in element slot of the array of four bit elements called c_list (controller list). The index slot is one-based.

void **srpt_get_class_port_info**(struct ib_dm_mad * mad)
copy ClassPortInfo to a management datagram

Parameters

struct ib_dm_mad * mad Datagram that will be sent as response to DM_ATTR_CLASS_PORT_INFO.

Description

See also section 16.3.3.1 ClassPortInfo in the InfiniBand Architecture Specification.

void **srpt_get_iou**(struct ib_dm_mad * mad)
write IOUnitInfo to a management datagram

Parameters

struct ib_dm_mad * mad Datagram that will be sent as response to DM_ATTR_IOU_INFO.

Description

See also section 16.3.3.3 IOUnitInfo in the InfiniBand Architecture Specification. See also section B.7, table B.6 in the SRP r16a document.

void **srpt_get_ioc**(struct srpt_port * sport, u32 slot, struct ib_dm_mad * mad)
write IOControllerprofile to a management datagram

Parameters

struct srpt_port * sport HCA port through which the MAD has been received.

u32 slot Slot number specified in DM_ATTR_IOC_PROFILE query.

struct ib_dm_mad * mad Datagram that will be sent as response to DM_ATTR_IOC_PROFILE.

Description

See also section 16.3.3.4 IOControllerProfile in the InfiniBand Architecture Specification. See also section B.7, table B.7 in the SRP r16a document.

void **srpt_get_svc_entries**(u64 ioc_guid, u16 slot, u8 hi, u8 lo, struct ib_dm_mad * mad)
write ServiceEntries to a management datagram

Parameters

u64 ioc_guid I/O controller GUID to use in reply.

u16 slot I/O controller number.

u8 hi End of the range of service entries to be specified in the reply.

u8 lo Start of the range of service entries to be specified in the reply..

struct ib_dm_mad * mad Datagram that will be sent as response to DM_ATTR_SVC_ENTRIES.

Description

See also section 16.3.3.5 ServiceEntries in the InfiniBand Architecture Specification. See also section B.7, table B.8 in the SRP r16a document.

void **srpt_mgmt_method_get**(struct srpt_port * sp, struct ib_mad * rq_mad, struct ib_dm_mad * rsp_mad)
process a received management datagram

Parameters

struct srpt_port * sp HCA port through which the MAD has been received.

struct ib_mad * rq_mad received MAD.

struct ib_dm_mad * rsp_mad response MAD.

void **srpt_mad_send_handler**(struct ib_mad_agent * mad_agent, struct ib_mad_send_wc * mad_wc)
MAD send completion callback

Parameters

struct ib_mad_agent * mad_agent Return value of ib_register_mad_agent().

struct ib_mad_send_wc * mad_wc Work completion reporting that the MAD has been sent.

void **srpt_mad_recv_handler**(struct ib_mad_agent * mad_agent, struct ib_mad_send_buf * send_buf, struct ib_mad_recv_wc * mad_wc)
MAD reception callback function

Parameters

struct ib_mad_agent * mad_agent Return value of ib_register_mad_agent().

struct ib_mad_send_buf * send_buf Not used.

struct ib_mad_recv_wc * mad_wc Work completion reporting that a MAD has been received.

int **srpt_refresh_port**(struct srpt_port * sport)
configure a HCA port

Parameters

struct srpt_port * sport SRPT HCA port.

Description

Enable InfiniBand management datagram processing, update the cached sm_lid, lid and gid values, and register a callback function for processing MADs on the specified port.

Note

It is safe to call this function more than once for the same port.

void **srpt_unregister_mad_agent**(struct srpt_device * sdev)
unregister MAD callback functions

Parameters

struct srpt_device * sdev SRPT HCA pointer.

Note

It is safe to call this function more than once for the same device.

struct srpt_ioctx * **srpt_alloc_ioctx**(struct srpt_device * sdev, int ioctx_size, struct kmem_cache * buf_cache, enum dma_data_direction dir)

allocate a SRPT I/O context structure

Parameters

struct srpt_device * sdev SRPT HCA pointer.

int ioctx_size I/O context size.

struct kmem_cache * buf_cache I/O buffer cache.

enum dma_data_direction dir DMA data direction.

void **srpt_free_ioctx**(struct srpt_device * sdev, struct srpt_ioctx * ioctx, struct kmem_cache * buf_cache, enum dma_data_direction dir)

free a SRPT I/O context structure

Parameters

struct srpt_device * sdev SRPT HCA pointer.

struct srpt_ioctx * ioctx I/O context pointer.

struct kmem_cache * buf_cache I/O buffer cache.

enum dma_data_direction dir DMA data direction.

struct srpt_ioctx ** **srpt_alloc_ioctx_ring**(struct srpt_device * sdev, int ring_size, int ioctx_size, struct kmem_cache * buf_cache, int alignment_offset, enum dma_data_direction dir)

allocate a ring of SRPT I/O context structures

Parameters

struct srpt_device * sdev Device to allocate the I/O context ring for.

int ring_size Number of elements in the I/O context ring.

int ioctx_size I/O context size.

struct kmem_cache * buf_cache I/O buffer cache.

int alignment_offset Offset in each ring buffer at which the SRP information unit starts.

enum dma_data_direction dir DMA data direction.

void **srpt_free_ioctx_ring**(struct srpt_ioctx ** ioctx_ring, struct srpt_device * sdev, int ring_size, struct kmem_cache * buf_cache, enum dma_data_direction dir)

free the ring of SRPT I/O context structures

Parameters

struct srpt_ioctx ** ioctx_ring I/O context ring to be freed.

struct srpt_device * sdev SRPT HCA pointer.

int ring_size Number of ring elements.

struct kmem_cache * buf_cache I/O buffer cache.

enum dma_data_direction dir DMA data direction.

enum srpt_command_state **srpt_set_cmd_state**(struct srpt_send_ioctx * ioctx, enum srpt_command_state new)
set the state of a SCSI command

Parameters

struct srpt_send_ioctx * ioctx Send I/O context.

enum srpt_command_state new New I/O context state.

Description

Does not modify the state of aborted commands. Returns the previous command state.

bool **srpt_test_and_set_cmd_state**(struct srpt_send_ioctx * ioctx, enum srpt_command_state old, enum srpt_command_state new)
test and set the state of a command

Parameters

struct srpt_send_ioctx * ioctx Send I/O context.

enum srpt_command_state old Current I/O context state.

enum srpt_command_state new New I/O context state.

Description

Returns true if and only if the previous command state was equal to ‘old’.

int **srpt_post_recv**(struct srpt_device * sdev, struct srpt_rdma_ch * ch, struct srpt_recv_ioctx * ioctx)
post an IB receive request

Parameters

struct srpt_device * sdev SRPT HCA pointer.

struct srpt_rdma_ch * ch SRPT RDMA channel.

struct srpt_recv_ioctx * ioctx Receive I/O context pointer.

int **srpt_zerolength_write**(struct srpt_rdma_ch * ch)
perform a zero-length RDMA write

Parameters

struct srpt_rdma_ch * ch SRPT RDMA channel.

Description

A quote from the InfiniBand specification: C9-88: For an HCA responder using Reliable Connection service, for each zero-length RDMA READ or WRITE request, the R_Key shall not be validated, even if the request includes Immediate data.

int **srpt_get_desc_tbl**(struct srpt_recv_ioctx * recv_ioctx, struct srpt_send_ioctx * ioctx, struct srp_cmd * srp_cmd, enum dma_data_direction * dir, struct scatterlist ** sg, unsigned int * sg_cnt, u64 * data_len, u16 imm_data_offset)
parse the data descriptors of a SRP_CMD request

Parameters

struct srpt_recv_ioctx * recv_ioctx I/O context associated with the received command **srp_cmd**.

struct srpt_send_ioctx * ioctx I/O context that will be used for responding to the initiator.

struct srp_cmd * srp_cmd Pointer to the SRP_CMD request data.

enum dma_data_direction * dir Pointer to the variable to which the transfer direction will be written.

struct scatterlist ** sg [out] scatterlist for the parsed SRP_CMD.

unsigned int * sg_cnt [out] length of **sg**.

u64 * data_len Pointer to the variable to which the total data length of all descriptors in the SRP_CMD request will be written.

u16 imm_data_offset [in] Offset in SRP_CMD requests at which immediate data starts.

Description

This function initializes ioctx->nrbuf and ioctx->r_bufs.

Returns -EINVAL when the SRP_CMD request contains inconsistent descriptors; -ENOMEM when memory allocation fails and zero upon success.

int **srpt_init_ch_qp**(struct srpt_rdma_ch * ch, struct ib_qp * qp)
initialize queue pair attributes

Parameters

struct srpt_rdma_ch * ch SRPT RDMA channel.

struct ib_qp * qp Queue pair pointer.

Description

Initialized the attributes of queue pair 'qp' by allowing local write, remote read and remote write. Also transitions 'qp' to state IB_QPS_INIT.

int **srpt_ch_qp_rtr**(struct srpt_rdma_ch * ch, struct ib_qp * qp)
change the state of a channel to 'ready to receive' (RTR)

Parameters

struct srpt_rdma_ch * ch channel of the queue pair.

struct ib_qp * qp queue pair to change the state of.

Description

Returns zero upon success and a negative value upon failure.

Note

currently a struct ib_qp_attr takes 136 bytes on a 64-bit system. If this structure ever becomes larger, it might be necessary to allocate it dynamically instead of on the stack.

int **srpt_ch_qp_rts**(struct srpt_rdma_ch * ch, struct ib_qp * qp)
change the state of a channel to 'ready to send' (RTS)

Parameters

struct srpt_rdma_ch * ch channel of the queue pair.

struct ib_qp * qp queue pair to change the state of.

Description

Returns zero upon success and a negative value upon failure.

Note

currently a struct ib_qp_attr takes 136 bytes on a 64-bit system. If this structure ever becomes larger, it might be necessary to allocate it dynamically instead of on the stack.

int **srpt_ch_qp_err**(struct srpt_rdma_ch * ch)
set the channel queue pair state to 'error'

Parameters

struct srpt_rdma_ch * ch SRPT RDMA channel.

struct srpt_send_ioctx * **srpt_get_send_ioctx**(struct srpt_rdma_ch * ch)
obtain an I/O context for sending to the initiator

Parameters

struct srpt_rdma_ch * ch SRPT RDMA channel.

int **srpt_abort_cmd**(struct srpt_send_ioctx * ioctx)
abort a SCSI command

Parameters

struct srpt_send_ioctx * ioctx I/O context associated with the SCSI command.

void **srpt_rdma_read_done**(struct ib_cq * cq, struct ib_wc * wc)
RDMA read completion callback

Parameters

struct ib_cq * cq Completion queue.

struct ib_wc * wc Work completion.

Description

XXX: what is now target_execute_cmd used to be asynchronous, and unmapping the data that has been transferred via IB RDMA had to be postponed until the check_stop_free() callback. None of this is necessary anymore and needs to be cleaned up.

int **srpt_build_cmd_rsp**(struct srpt_rdma_ch * ch, struct srpt_send_ioctx * ioctx, u64 tag, int status)
build a SRP_RSP response

Parameters

struct srpt_rdma_ch * ch RDMA channel through which the request has been received.

struct srpt_send_ioctx * ioctx I/O context associated with the SRP_CMD request. The response will be built in the buffer ioctx->buf points at and hence this function will overwrite the request data.

u64 tag tag of the request for which this response is being generated.

int status value for the STATUS field of the SRP_RSP information unit.

Description

Returns the size in bytes of the SRP_RSP response.

An SRP_RSP response contains a SCSI status or service response. See also section 6.9 in the SRP r16a document for the format of an SRP_RSP response. See also SPC-2 for more information about sense data.

int **srpt_build_tskmgmt_rsp**(struct srpt_rdma_ch * ch, struct srpt_send_ioctx * ioctx, u8 rsp_code, u64 tag)
build a task management response

Parameters

struct srpt_rdma_ch * ch RDMA channel through which the request has been received.

struct srpt_send_ioctx * ioctx I/O context in which the SRP_RSP response will be built.

u8 rsp_code RSP_CODE that will be stored in the response.

u64 tag Tag of the request for which this response is being generated.

Description

Returns the size in bytes of the SRP_RSP response.

An SRP_RSP response contains a SCSI status or service response. See also section 6.9 in the SRP r16a document for the format of an SRP_RSP response.

void **srpt_handle_cmd**(struct srpt_rdma_ch * ch, struct srpt_recv_ioctx * recv_ioctx, struct srpt_send_ioctx * send_ioctx)
process a SRP_CMD information unit

Parameters

struct srpt_rdma_ch * ch SRPT RDMA channel.

struct srpt_recv_ioctx * recv_ioctx Receive I/O context.

struct srpt_send_ioctx * send_ioctx Send I/O context.

void **srpt_handle_tsk_mgmt**(struct srpt_rdma_ch * ch, struct srpt_recv_ioctx * recv_ioctx, struct srpt_send_ioctx * send_ioctx)
process a SRP_TSK_MGMT information unit

Parameters

struct srpt_rdma_ch * ch SRPT RDMA channel.

struct srpt_recv_ioctx * recv_ioctx Receive I/O context.

struct srpt_send_ioctx * send_ioctx Send I/O context.

Description

Returns 0 if and only if the request will be processed by the target core.

For more information about SRP_TSK_MGMT information units, see also section 6.7 in the SRP r16a document.

bool **srpt_handle_new_iu**(struct srpt_rdma_ch * ch, struct srpt_recv_ioctx * recv_ioctx)
process a newly received information unit

Parameters

struct srpt_rdma_ch * ch RDMA channel through which the information unit has been received.

struct srpt_recv_ioctx * recv_ioctx Receive I/O context associated with the information unit.

void **srpt_send_done**(struct ib_cq * cq, struct ib_wc * wc)
send completion callback

Parameters

struct ib_cq * cq Completion queue.

struct ib_wc * wc Work completion.

Note

Although this has not yet been observed during tests, at least in theory it is possible that the `srpt_get_send_ioctx()` call invoked by `srpt_handle_new_iu()` fails. This is possible because the req_lim_delta value in each response is set to one, and it is possible that this response makes the initiator send a new request before the send completion for that response has been processed. This could e.g. happen if the call to srpt_put_send_iotcx() is delayed because of a higher priority interrupt or if IB retransmission causes generation of the send completion to be delayed. Incoming information units for which `srpt_get_send_ioctx()` fails are queued on cmd_wait_list. The code below processes these delayed requests one at a time.

int **srpt_create_ch_ib**(struct srpt_rdma_ch * ch)
create receive and send completion queues

Parameters

struct srpt_rdma_ch * ch SRPT RDMA channel.

bool **srpt_close_ch**(struct srpt_rdma_ch * ch)
close a RDMA channel

Parameters

struct srpt_rdma_ch * ch SRPT RDMA channel.

Description

Make sure all resources associated with the channel will be deallocated at an appropriate time.

Returns true if and only if the channel state has been modified into CH_DRAINING.

int **srpt_cm_req_recv**(struct srpt_device *const sdev, struct ib_cm_id * ib_cm_id, struct rdma_cm_id * rdma_cm_id, u8 port_num, __be16 pkey, const struct srp_login_req * req, const char * src_addr)
process the event IB_CM_REQ_RECEIVED

Parameters

struct srpt_device *const sdev HCA through which the login request was received.

struct ib_cm_id * ib_cm_id IB/CM connection identifier in case of IB/CM.

struct rdma_cm_id * rdma_cm_id RDMA/CM connection identifier in case of RDMA/CM.

u8 port_num Port through which the REQ message was received.

__be16 pkey P_Key of the incoming connection.

const struct srp_login_req * req SRP login request.

const char * src_addr GID (IB/CM) or IP address (RDMA/CM) of the port that submitted the login request.

Description

Ownership of the cm_id is transferred to the target session if this function returns zero. Otherwise the caller remains the owner of cm_id.

void **srpt_cm_rtu_recv**(struct srpt_rdma_ch * ch)
process an IB_CM_RTU_RECEIVED or USER_ESTABLISHED event

Parameters

struct srpt_rdma_ch * ch SRPT RDMA channel.

Description

An RTU (ready to use) message indicates that the connection has been established and that the recipient may begin transmitting.

int **srpt_cm_handler**(struct ib_cm_id * cm_id, const struct ib_cm_event * event)
IB connection manager callback function

Parameters

struct ib_cm_id * cm_id IB/CM connection identifier.

const struct ib_cm_event * event IB/CM event.

Description

A non-zero return value will cause the caller destroy the CM ID.

Note

`srpt_cm_handler()` must only return a non-zero value when transferring ownership of the cm_id to a channel by `srpt_cm_req_recv()` failed. Returning a non-zero value in any other case will trigger a race with the ib_destroy_cm_id() call in srpt_release_channel().

void **srpt_queue_response**(struct se_cmd * cmd)
transmit the response to a SCSI command

Parameters

struct se_cmd * cmd SCSI target command.

Description

Callback function called by the TCM core. Must not block since it can be invoked on the context of the IB completion handler.

int **srpt_release_sport**(struct srpt_port * sport)
disable login and wait for associated channels

Parameters

struct srpt_port * sport SRPT HCA port.

int **srpt_add_one**(struct ib_device * device)
InfiniBand device addition callback function

Parameters

struct ib_device * device Describes a HCA.

void **srpt_remove_one**(struct ib_device * device, void * client_data)
InfiniBand device removal callback function

Parameters

struct ib_device * device Describes a HCA.

void * client_data The value passed as the third argument to `ib_set_client_data()`.

void **srpt_close_session**(struct se_session * se_sess)
forcibly close a session

Parameters

struct se_session * se_sess SCSI target session.

Description

Callback function invoked by the TCM core to clean up sessions associated with a node ACL when the user invokes rmdir /sys/kernel/config/target/$driver/$port/$tpg/acls/$i_port_id

u32 **srpt_sess_get_index**(struct se_session * se_sess)
return the value of scsiAttIntrPortIndex (SCSI-MIB)

Parameters

struct se_session * se_sess SCSI target session.

Description

A quote from RFC 4455 (SCSI-MIB) about this MIB object: This object represents an arbitrary integer used to uniquely identify a particular attached remote initiator port to a particular SCSI target port within a particular SCSI target device within a particular SCSI instance.

int **srpt_parse_i_port_id**(u8 i_port_id, const char * name)
parse an initiator port ID

Parameters

u8 i_port_id Binary 128-bit port ID.

const char * name ASCII representation of a 128-bit initiator port ID.

struct se_portal_group * **srpt_make_tpg**(struct se_wwn * wwn, const char * name)
configfs callback invoked for mkdir /sys/kernel/config/target/$driver/$port/$tpg

Parameters

struct se_wwn * wwn Corresponds to $driver/$port.

const char * name $tpg.

void **srpt_drop_tpg**(struct se_portal_group * tpg)
configfs callback invoked for rmdir /sys/kernel/config/target/$driver/$port/$tpg

Parameters

struct se_portal_group * tpg Target portal group to deregister.

struct se_wwn * **srpt_make_tport**(struct target_fabric_configfs * tf, struct config_group * group, const char * name)
configfs callback invoked for mkdir /sys/kernel/config/target/$driver/$port

Parameters

struct target_fabric_configfs * tf Not used.

struct config_group * group Not used.

const char * name $port.

void **srpt_drop_tport**(struct se_wwn * wwn)
configfs callback invoked for rmdir /sys/kernel/config/target/$driver/$port

Parameters

struct se_wwn * wwn $port.

int **srpt_init_module**(void)
kernel module initialization

Parameters

void no arguments

Note

Since `ib_register_client()` registers callback functions, and since at least one of these callback functions (`srpt_add_one()`) calls target core functions, this driver must be registered with the target core before `ib_register_client()` is called.

14.4.4 iSCSI Extensions for RDMA (iSER) target support

void **isert_conn_terminate**(struct isert_conn * isert_conn)
Initiate connection termination

Parameters

struct isert_conn * isert_conn isert connection struct

Notes

In case the connection state is BOUND, move state to TEMINATING and start teardown sequence (rdma_disconnect). In case the connection state is UP, complete flush as well.

Description

This routine must be called with mutex held. Thus it is safe to call multiple times.

void **isert_put_unsol_pending_cmds**(struct iscsi_conn * conn)
Drop commands waiting for unsolicitate dataout

Parameters

struct iscsi_conn * conn iscsi connection

Description

We might still have commands that are waiting for unsolicited dataouts messages. We must put the extra reference on those before blocking on the target_wait_for_session_cmds

CHAPTER

FIFTEEN

SOUND DEVICES

void **snd_card_unref**(struct snd_card * card)
Unreference the card object

Parameters

struct snd_card * card the card object to unreference

Description

Call this function for the card object that was obtained via `snd_card_ref()` or `snd_lookup_minor_data()`.

snd_printk(fmt, ⋯)
printk wrapper

Parameters

fmt format string

... variable arguments

Description

Works like `printk()` but prints the file and the line of the caller when configured with CONFIG_SND_VERBOSE_PRINTK.

snd_printd(fmt, ⋯)
debug printk

Parameters

fmt format string

... variable arguments

Description

Works like `snd_printk()` for debugging purposes. Ignored when CONFIG_SND_DEBUG is not set.

snd_BUG()
give a BUG warning message and stack trace

Parameters

Description

Calls WARN() if CONFIG_SND_DEBUG is set. Ignored when CONFIG_SND_DEBUG is not set.

snd_printd_ratelimit()

Parameters

snd_BUG_ON(cond)
debugging check macro

Parameters

cond condition to evaluate

Description

Has the same behavior as WARN_ON when CONFIG_SND_DEBUG is set, otherwise just evaluates the conditional and returns the value.

snd_printdd(format, ⋯)
debug printk

Parameters

format format string

... variable arguments

Description

Works like `snd_printk()` for debugging purposes. Ignored when CONFIG_SND_DEBUG_VERBOSE is not set.

int **register_sound_special_device**(const struct file_operations * fops, int unit, struct device * dev)
register a special sound node

Parameters

const struct file_operations * fops File operations for the driver

int unit Unit number to allocate

struct device * dev device pointer

Allocate a special sound device by minor number from the sound subsystem.

Return

The allocated number is returned on success. On failure, a negative error code is returned.

int **register_sound_mixer**(const struct file_operations * fops, int dev)
register a mixer device

Parameters

const struct file_operations * fops File operations for the driver

int dev Unit number to allocate

Allocate a mixer device. Unit is the number of the mixer requested. Pass -1 to request the next free mixer unit.

Return

On success, the allocated number is returned. On failure, a negative error code is returned.

int **register_sound_dsp**(const struct file_operations * fops, int dev)
register a DSP device

Parameters

const struct file_operations * fops File operations for the driver

int dev Unit number to allocate

Allocate a DSP device. Unit is the number of the DSP requested. Pass -1 to request the next free DSP unit.

This function allocates both the audio and dsp device entries together and will always allocate them as a matching pair - eg dsp3/audio3

Return

On success, the allocated number is returned. On failure, a negative error code is returned.

void **unregister_sound_special**(int unit)
unregister a special sound device

Parameters

int unit unit number to allocate

Release a sound device that was allocated with register_sound_special(). The unit passed is the return value from the register function.

void **unregister_sound_mixer**(int unit)
unregister a mixer

Parameters

int unit unit number to allocate

Release a sound device that was allocated with `register_sound_mixer()`. The unit passed is the return value from the register function.

void **unregister_sound_dsp**(int unit)
unregister a DSP device

Parameters

int unit unit number to allocate

Release a sound device that was allocated with `register_sound_dsp()`. The unit passed is the return value from the register function.

Both of the allocated units are released together automatically.

int **snd_pcm_stream_linked**(struct snd_pcm_substream * substream)
Check whether the substream is linked with others

Parameters

struct snd_pcm_substream * substream substream to check

Description

Returns true if the given substream is being linked with others.

snd_pcm_stream_lock_irqsave(substream, flags)
Lock the PCM stream

Parameters

substream PCM substream

flags irq flags

Description

This locks the PCM stream like `snd_pcm_stream_lock()` but with the local IRQ (only when nonatomic is false). In nonatomic case, this is identical as `snd_pcm_stream_lock()`.

snd_pcm_group_for_each_entry(s, substream)
iterate over the linked substreams

Parameters

s the iterator

substream the substream

Description

Iterate over the all linked substreams to the given **substream**. When **substream** isn't linked with any others, this gives returns **substream** itself once.

int **snd_pcm_running**(struct snd_pcm_substream * substream)
Check whether the substream is in a running state

Parameters

struct snd_pcm_substream * substream substream to check

Description

Returns true if the given substream is in the state RUNNING, or in the state DRAINING for playback.

ssize_t **bytes_to_samples**(struct snd_pcm_runtime * runtime, ssize_t size)
Unit conversion of the size from bytes to samples

Parameters

struct snd_pcm_runtime * runtime PCM runtime instance

ssize_t size size in bytes

snd_pcm_sframes_t **bytes_to_frames**(struct snd_pcm_runtime * runtime,
ssize_t size)
Unit conversion of the size from bytes to frames

Parameters

struct snd_pcm_runtime * runtime PCM runtime instance

ssize_t size size in bytes

ssize_t **samples_to_bytes**(struct snd_pcm_runtime * runtime, ssize_t size)
Unit conversion of the size from samples to bytes

Parameters

struct snd_pcm_runtime * runtime PCM runtime instance

ssize_t size size in samples

ssize_t **frames_to_bytes**(struct snd_pcm_runtime * runtime, snd_pcm_sframes_t size)
Unit conversion of the size from frames to bytes

Parameters

struct snd_pcm_runtime * runtime PCM runtime instance

snd_pcm_sframes_t size size in frames

int **frame_aligned**(struct snd_pcm_runtime * runtime, ssize_t bytes)
Check whether the byte size is aligned to frames

Parameters

struct snd_pcm_runtime * runtime PCM runtime instance

ssize_t bytes size in bytes

size_t **snd_pcm_lib_buffer_bytes**(struct snd_pcm_substream * substream)
Get the buffer size of the current PCM in bytes

Parameters

struct snd_pcm_substream * substream PCM substream

size_t **snd_pcm_lib_period_bytes**(struct snd_pcm_substream * substream)
Get the period size of the current PCM in bytes

Parameters

struct snd_pcm_substream * substream PCM substream

snd_pcm_uframes_t **snd_pcm_playback_avail**(struct snd_pcm_runtime * runtime)
Get the available (writable) space for playback

Parameters

struct snd_pcm_runtime * runtime PCM runtime instance

Description

Result is between 0 …(boundary - 1)

snd_pcm_uframes_t **snd_pcm_capture_avail**(struct snd_pcm_runtime * runtime)
Get the available (readable) space for capture

Parameters

struct snd_pcm_runtime * runtime PCM runtime instance

Description

Result is between 0 …(boundary - 1)

snd_pcm_sframes_t **snd_pcm_playback_hw_avail**(struct snd_pcm_runtime * runtime)
Get the queued space for playback

Parameters

struct snd_pcm_runtime * runtime PCM runtime instance

snd_pcm_sframes_t **snd_pcm_capture_hw_avail**(struct snd_pcm_runtime * runtime)
Get the free space for capture

Parameters

struct snd_pcm_runtime * runtime PCM runtime instance

int **snd_pcm_playback_ready**(struct snd_pcm_substream * substream)
check whether the playback buffer is available

Parameters

struct snd_pcm_substream * substream the pcm substream instance

Description

Checks whether enough free space is available on the playback buffer.

Return

Non-zero if available, or zero if not.

int **snd_pcm_capture_ready**(struct snd_pcm_substream * substream)
check whether the capture buffer is available

Parameters

struct snd_pcm_substream * substream the pcm substream instance

Description

Checks whether enough capture data is available on the capture buffer.

Return

Non-zero if available, or zero if not.

int **snd_pcm_playback_data**(struct snd_pcm_substream * substream)
check whether any data exists on the playback buffer

Parameters

struct snd_pcm_substream * substream the pcm substream instance

Description

Checks whether any data exists on the playback buffer.

Return

Non-zero if any data exists, or zero if not. If stop_threshold is bigger or equal to boundary, then this function returns always non-zero.

int **snd_pcm_playback_empty**(struct snd_pcm_substream * substream)
check whether the playback buffer is empty

Parameters

struct snd_pcm_substream * substream the pcm substream instance

Description

Checks whether the playback buffer is empty.

Return

Non-zero if empty, or zero if not.

int **snd_pcm_capture_empty**(struct snd_pcm_substream * substream)
check whether the capture buffer is empty

Parameters

struct snd_pcm_substream * substream the pcm substream instance

Description

Checks whether the capture buffer is empty.

Return

Non-zero if empty, or zero if not.

void **snd_pcm_trigger_done**(struct snd_pcm_substream * substream, struct snd_pcm_substream * master)
Mark the master substream

Parameters

struct snd_pcm_substream * substream the pcm substream instance

struct snd_pcm_substream * master the linked master substream

Description

When multiple substreams of the same card are linked and the hardware supports the single-shot operation, the driver calls this in the loop in `snd_pcm_group_for_each_entry()` for marking the substream as “done”. Then most of trigger operations are performed only to the given master substream.

The trigger_master mark is cleared at timestamp updates at the end of trigger operations.

unsigned int **params_channels**(const struct snd_pcm_hw_params * p)
Get the number of channels from the hw params

Parameters

const struct snd_pcm_hw_params * p hw params

unsigned int **params_rate**(const struct snd_pcm_hw_params * p)
Get the sample rate from the hw params

Parameters

const struct snd_pcm_hw_params * p hw params

unsigned int **params_period_size**(const struct snd_pcm_hw_params * p)
Get the period size (in frames) from the hw params

Parameters

const struct snd_pcm_hw_params * p hw params

unsigned int **params_periods**(const struct snd_pcm_hw_params * p)
Get the number of periods from the hw params

Parameters

const struct snd_pcm_hw_params * p hw params

unsigned int **params_buffer_size**(const struct snd_pcm_hw_params * p)
Get the buffer size (in frames) from the hw params

Parameters

const struct snd_pcm_hw_params * p hw params

unsigned int **params_buffer_bytes**(const struct snd_pcm_hw_params * p)
Get the buffer size (in bytes) from the hw params

Parameters

const struct snd_pcm_hw_params * p hw params

int **snd_pcm_hw_constraint_single**(struct snd_pcm_runtime * runtime, snd_pcm_hw_param_t var, unsigned int val)
Constrain parameter to a single value

Parameters

struct snd_pcm_runtime * runtime PCM runtime instance

snd_pcm_hw_param_t var The hw_params variable to constrain

unsigned int val The value to constrain to

Return

Positive if the value is changed, zero if it's not changed, or a negative error code.

int **snd_pcm_format_cpu_endian**(snd_pcm_format_t format)
Check the PCM format is CPU-endian

Parameters

snd_pcm_format_t format the format to check

Return

1 if the given PCM format is CPU-endian, 0 if opposite, or a negative error code if endian not specified.

void **snd_pcm_set_runtime_buffer**(struct snd_pcm_substream * substream, struct snd_dma_buffer * bufp)
Set the PCM runtime buffer

Parameters

struct snd_pcm_substream * substream PCM substream to set

struct snd_dma_buffer * bufp the buffer information, NULL to clear

Description

Copy the buffer information to runtime->dma_buffer when **bufp** is non-NULL. Otherwise it clears the current buffer information.

void **snd_pcm_gettime**(struct snd_pcm_runtime * runtime, struct timespec64 * tv)
Fill the timespec64 depending on the timestamp mode

Parameters

struct snd_pcm_runtime * runtime PCM runtime instance

struct timespec64 * tv timespec64 to fill

int **snd_pcm_lib_alloc_vmalloc_buffer**(struct snd_pcm_substream * substream, size_t size)
allocate virtual DMA buffer

Parameters

struct snd_pcm_substream * substream the substream to allocate the buffer to

size_t size the requested buffer size, in bytes

Description

Allocates the PCM substream buffer using vmalloc(), i.e., the memory is contiguous in kernel virtual space, but not in physical memory. Use this if the buffer is accessed by kernel code but not by device DMA.

Return

1 if the buffer was changed, 0 if not changed, or a negative error code.

int **snd_pcm_lib_alloc_vmalloc_32_buffer**(struct snd_pcm_substream * substream, size_t size)
allocate 32-bit-addressable buffer

Parameters

struct snd_pcm_substream * substream the substream to allocate the buffer to

size_t size the requested buffer size, in bytes

Description

This function works like `snd_pcm_lib_alloc_vmalloc_buffer()`, but uses vmalloc_32(), i.e., the pages are allocated from 32-bit-addressable memory.

Return

1 if the buffer was changed, 0 if not changed, or a negative error code.

dma_addr_t **snd_pcm_sgbuf_get_addr**(struct snd_pcm_substream * substream, unsigned int ofs)
Get the DMA address at the corresponding offset

Parameters

struct snd_pcm_substream * substream PCM substream

unsigned int ofs byte offset

void * **snd_pcm_sgbuf_get_ptr**(struct snd_pcm_substream * substream, unsigned int ofs)
Get the virtual address at the corresponding offset

Parameters

struct snd_pcm_substream * substream PCM substream

unsigned int ofs byte offset

unsigned int **snd_pcm_sgbuf_get_chunk_size**(struct snd_pcm_substream * substream, unsigned int ofs, unsigned int size)
Compute the max size that fits within the contig. page from the given size

Parameters

struct snd_pcm_substream * substream PCM substream

unsigned int ofs byte offset

unsigned int size byte size to examine

void **snd_pcm_mmap_data_open**(struct vm_area_struct * area)
increase the mmap counter

Parameters

struct vm_area_struct * area VMA

Description

PCM mmap callback should handle this counter properly

void **snd_pcm_mmap_data_close**(struct vm_area_struct * area)
decrease the mmap counter

Parameters

struct vm_area_struct * area VMA

Description

PCM mmap callback should handle this counter properly

void **snd_pcm_limit_isa_dma_size**(int dma, size_t * max)
Get the max size fitting with ISA DMA transfer

Parameters

int dma DMA number

size_t * max pointer to store the max size

const char * **snd_pcm_stream_str**(struct snd_pcm_substream * substream)
Get a string naming the direction of a stream

Parameters

struct snd_pcm_substream * substream the pcm substream instance

Return

A string naming the direction of the stream.

struct snd_pcm_substream * **snd_pcm_chmap_substream**(struct snd_pcm_chmap * info, unsigned int idx)
get the PCM substream assigned to the given chmap info

Parameters

struct snd_pcm_chmap * info chmap information

unsigned int idx the substream number index

u64 **pcm_format_to_bits**(snd_pcm_format_t pcm_format)
Strong-typed conversion of pcm_format to bitwise

Parameters

snd_pcm_format_t pcm_format PCM format

pcm_for_each_format(f)
helper to iterate for each format type

Parameters

f the iterator variable in snd_pcm_format_t type

const char * **snd_pcm_format_name**(snd_pcm_format_t format)
Return a name string for the given PCM format

Parameters

snd_pcm_format_t format PCM format

int **snd_pcm_new_stream**(struct snd_pcm * pcm, int stream, int substream_count)
create a new PCM stream

Parameters

struct snd_pcm * pcm the pcm instance

int stream the stream direction, SNDRV_PCM_STREAM_XXX

int substream_count the number of substreams

Description

Creates a new stream for the pcm. The corresponding stream on the pcm must have been empty before calling this, i.e. zero must be given to the argument of `snd_pcm_new()`.

Return

Zero if successful, or a negative error code on failure.

int **snd_pcm_new**(struct snd_card * card, const char * id, int device, int playback_count, int capture_count, struct snd_pcm ** rpcm)
create a new PCM instance

Parameters

struct snd_card * card the card instance

const char * id the id string

int device the device index (zero based)

int playback_count the number of substreams for playback

int capture_count the number of substreams for capture

struct snd_pcm ** rpcm the pointer to store the new pcm instance

Description

Creates a new PCM instance.

The pcm operators have to be set afterwards to the new instance via `snd_pcm_set_ops()`.

Return

Zero if successful, or a negative error code on failure.

int **snd_pcm_new_internal**(struct snd_card * card, const char * id, int device, int playback_count, int capture_count, struct snd_pcm ** rpcm)
create a new internal PCM instance

Parameters

struct snd_card * card the card instance

const char * id the id string

int device the device index (zero based - shared with normal PCMs)

int playback_count the number of substreams for playback

int capture_count the number of substreams for capture

struct snd_pcm ** rpcm the pointer to store the new pcm instance

Description

Creates a new internal PCM instance with no userspace device or procfs entries. This is used by ASoC Back End PCMs in order to create a PCM that will only be used internally by kernel drivers. i.e. it cannot be opened by userspace. It provides existing ASoC components drivers with a substream and access to any private data.

The pcm operators have to be set afterwards to the new instance via `snd_pcm_set_ops()`.

Return

Zero if successful, or a negative error code on failure.

int **snd_pcm_notify**(struct snd_pcm_notify * notify, int nfree)
Add/remove the notify list

Parameters

struct snd_pcm_notify * notify PCM notify list

int nfree 0 = register, 1 = unregister

Description

This adds the given notifier to the global list so that the callback is called for each registered PCM devices. This exists only for PCM OSS emulation, so far.

int **snd_device_new**(struct snd_card * card, enum snd_device_type type, void * device_data, const struct snd_device_ops * ops)
create an ALSA device component

Parameters

struct snd_card * card the card instance

enum snd_device_type type the device type, SNDRV_DEV_XXX

void * device_data the data pointer of this device

const struct snd_device_ops * ops the operator table

Description

Creates a new device component for the given data pointer. The device will be assigned to the card and managed together by the card.

The data pointer plays a role as the identifier, too, so the pointer address must be unique and unchanged.

Return

Zero if successful, or a negative error code on failure.

void **snd_device_disconnect**(struct snd_card * card, void * device_data)
disconnect the device

Parameters

struct snd_card * card the card instance

void * device_data the data pointer to disconnect

Description

Turns the device into the disconnection state, invoking dev_disconnect callback, if the device was already registered.

Usually called from `snd_card_disconnect()`.

Return

Zero if successful, or a negative error code on failure or if the device not found.

void **snd_device_free**(struct snd_card * card, void * device_data)
release the device from the card

Parameters

struct snd_card * card the card instance

void * device_data the data pointer to release

Description

Removes the device from the list on the card and invokes the callbacks, dev_disconnect and dev_free, corresponding to the state. Then release the device.

int **snd_device_register**(struct snd_card * card, void * device_data)
register the device

Parameters

struct snd_card * card the card instance

void * device_data the data pointer to register

Description

Registers the device which was already created via `snd_device_new()`. Usually this is called from `snd_card_register()`, but it can be called later if any new devices are created after invocation of `snd_card_register()`.

Return

Zero if successful, or a negative error code on failure or if the device not found.

int **snd_device_get_state**(struct snd_card * card, void * device_data)
Get the current state of the given device

Parameters

struct snd_card * card the card instance

void * device_data the data pointer to release

Description

Returns the current state of the given device object. For the valid device, either **SNDRV_DEV_BUILD**, **SNDRV_DEV_REGISTERED** or **SNDRV_DEV_DISCONNECTED** is returned. Or for a non-existing device, -1 is returned as an error.

int **snd_info_get_line**(struct snd_info_buffer * buffer, char * line, int len)
read one line from the procfs buffer

Parameters

struct snd_info_buffer * buffer the procfs buffer

char * line the buffer to store

int len the max. buffer size

Description

Reads one line from the buffer and stores the string.

Return

Zero if successful, or 1 if error or EOF.

const char * **snd_info_get_str**(char * dest, const char * src, int len)
parse a string token

Parameters

char * dest the buffer to store the string token

const char * src the original string

int len the max. length of token - 1

Description

Parses the original string and copy a token to the given string buffer.

Return

The updated pointer of the original string so that it can be used for the next call.

struct snd_info_entry * **snd_info_create_module_entry**(struct module * module, const char * name, struct snd_info_entry * parent)
create an info entry for the given module

Parameters

struct module * module the module pointer

const char * name the file name

struct snd_info_entry * parent the parent directory

Description

Creates a new info entry and assigns it to the given module.

Return

The pointer of the new instance, or `NULL` on failure.

struct snd_info_entry * **snd_info_create_card_entry**(struct snd_card * card, const char * name, struct snd_info_entry * parent)
create an info entry for the given card

Parameters

struct snd_card * card the card instance

const char * name the file name

struct snd_info_entry * parent the parent directory

Description

Creates a new info entry and assigns it to the given card.

Return

The pointer of the new instance, or `NULL` on failure.

void **snd_info_free_entry**(struct snd_info_entry * entry)
release the info entry

Parameters

struct snd_info_entry * entry the info entry

Description

Releases the info entry.

int **snd_info_register**(struct snd_info_entry * entry)
register the info entry

Parameters

struct snd_info_entry * entry the info entry

Description

Registers the proc info entry. The all children entries are registered recursively.

Return

Zero if successful, or a negative error code on failure.

int **snd_card_rw_proc_new**(struct snd_card * card, const char * name, void * private_data, void (*read)(struct snd_info_entry *, struct snd_info_buffer *), void (*write) (struct snd_info_entry *entry, struct snd_info_buffer *buffer))

Create a read/write text proc file entry for the card

Parameters

struct snd_card * card the card instance

const char * name the file name

void * private_data the arbitrary private data

void (*)(struct snd_info_entry *, struct snd_info_buffer *) read the read callback

void (*)(struct snd_info_entry *entry, struct snd_info_buffer *buffer) write the write callback, NULL for read-only

Description

This proc file entry will be registered via `snd_card_register()` call, and it will be removed automatically at the card removal, too.

int **snd_rawmidi_receive**(struct snd_rawmidi_substream * substream, const unsigned char * buffer, int count)

receive the input data from the device

Parameters

struct snd_rawmidi_substream * substream the rawmidi substream

const unsigned char * buffer the buffer pointer

int count the data size to read

Description

Reads the data from the internal buffer.

Return

The size of read data, or a negative error code on failure.

int **snd_rawmidi_transmit_empty**(struct snd_rawmidi_substream * substream)

check whether the output buffer is empty

Parameters

struct snd_rawmidi_substream * substream the rawmidi substream

Return

1 if the internal output buffer is empty, 0 if not.

int **__snd_rawmidi_transmit_peek**(struct snd_rawmidi_substream * substream, unsigned char * buffer, int count)
copy data from the internal buffer

Parameters

struct snd_rawmidi_substream * substream the rawmidi substream

unsigned char * buffer the buffer pointer

int count data size to transfer

Description

This is a variant of `snd_rawmidi_transmit_peek()` without spinlock.

int **snd_rawmidi_transmit_peek**(struct snd_rawmidi_substream * substream, unsigned char * buffer, int count)
copy data from the internal buffer

Parameters

struct snd_rawmidi_substream * substream the rawmidi substream

unsigned char * buffer the buffer pointer

int count data size to transfer

Description

Copies data from the internal output buffer to the given buffer.

Call this in the interrupt handler when the midi output is ready, and call `snd_rawmidi_transmit_ack()` after the transmission is finished.

Return

The size of copied data, or a negative error code on failure.

int **__snd_rawmidi_transmit_ack**(struct snd_rawmidi_substream * substream, int count)
acknowledge the transmission

Parameters

struct snd_rawmidi_substream * substream the rawmidi substream

int count the transferred count

Description

This is a variant of `__snd_rawmidi_transmit_ack()` without spinlock.

int **snd_rawmidi_transmit_ack**(struct snd_rawmidi_substream * substream, int count)
acknowledge the transmission

Parameters

struct snd_rawmidi_substream * substream the rawmidi substream

int count the transferred count

Description

Advances the hardware pointer for the internal output buffer with the given size and updates the condition. Call after the transmission is finished.

Return

The advanced size if successful, or a negative error code on failure.

int **snd_rawmidi_transmit**(struct snd_rawmidi_substream * substream, unsigned char * buffer, int count)
copy from the buffer to the device

Parameters

struct snd_rawmidi_substream * substream the rawmidi substream

unsigned char * buffer the buffer pointer

int count the data size to transfer

Description

Copies data from the buffer to the device and advances the pointer.

Return

The copied size if successful, or a negative error code on failure.

int **snd_rawmidi_proceed**(struct snd_rawmidi_substream * substream)
Discard the all pending bytes and proceed

Parameters

struct snd_rawmidi_substream * substream rawmidi substream

Return

the number of discarded bytes

int **snd_rawmidi_new**(struct snd_card * card, char * id, int device, int output_count, int input_count, struct snd_rawmidi ** rrawmidi)
create a rawmidi instance

Parameters

struct snd_card * card the card instance

char * id the id string

int device the device index

int output_count the number of output streams

int input_count the number of input streams

struct snd_rawmidi ** rrawmidi the pointer to store the new rawmidi instance

Description

Creates a new rawmidi instance. Use `snd_rawmidi_set_ops()` to set the operators to the new instance.

Return

Zero if successful, or a negative error code on failure.

void **snd_rawmidi_set_ops**(struct snd_rawmidi * rmidi, int stream, const struct snd_rawmidi_ops * ops)
set the rawmidi operators

Parameters

struct snd_rawmidi * rmidi the rawmidi instance

int stream the stream direction, SNDRV_RAWMIDI_STREAM_XXX

const struct snd_rawmidi_ops * ops the operator table

Description

Sets the rawmidi operators for the given stream direction.

void **snd_request_card**(int card)
try to load the card module

Parameters

int card the card number

Description

Tries to load the module "snd-card-X" for the given card number via request_module. Returns immediately if already loaded.

void * **snd_lookup_minor_data**(unsigned int minor, int type)
get user data of a registered device

Parameters

unsigned int minor the minor number

int type device type (SNDRV_DEVICE_TYPE_XXX)

Description

Checks that a minor device with the specified type is registered, and returns its user data pointer.

This function increments the reference counter of the card instance if an associated instance with the given minor number and type is found. The caller must call `snd_card_unref()` appropriately later.

Return

The user data pointer if the specified device is found. `NULL` otherwise.

int **snd_register_device**(int type, struct snd_card * card, int dev, const struct file_operations * f_ops, void * private_data, struct device * device)
Register the ALSA device file for the card

Parameters

int type the device type, SNDRV_DEVICE_TYPE_XXX

struct snd_card * card the card instance

int dev the device index

const struct file_operations * f_ops the file operations

void * private_data user pointer for f_ops->open()

struct device * device the device to register

Description

Registers an ALSA device file for the given card. The operators have to be set in reg parameter.

Return

Zero if successful, or a negative error code on failure.

int **snd_unregister_device**(struct device * dev)
unregister the device on the given card

Parameters

struct device * dev the device instance

Description

Unregisters the device file already registered via `snd_register_device()`.

Return

Zero if successful, or a negative error code on failure.

int **copy_to_user_fromio**(void __user * dst, const volatile void __iomem * src, size_t count)
copy data from mmio-space to user-space

Parameters

void __user * dst the destination pointer on user-space

const volatile void __iomem * src the source pointer on mmio

size_t count the data size to copy in bytes

Description

Copies the data from mmio-space to user-space.

Return

Zero if successful, or non-zero on failure.

int **copy_from_user_toio**(volatile void __iomem * dst, const void __user * src, size_t count)
copy data from user-space to mmio-space

Parameters

volatile void __iomem * dst the destination pointer on mmio-space

const void __user * src the source pointer on user-space

size_t count the data size to copy in bytes

Description

Copies the data from user-space to mmio-space.

Return

Zero if successful, or non-zero on failure.

void **snd_pcm_lib_preallocate_free_for_all**(struct snd_pcm * pcm)
release all pre-allocated buffers on the pcm

Parameters

struct snd_pcm * pcm the pcm instance

Description

Releases all the pre-allocated buffers on the given pcm.

void **snd_pcm_lib_preallocate_pages**(struct snd_pcm_substream * substream, int type, struct device * data, size_t size, size_t max)
pre-allocation for the given DMA type

Parameters

struct snd_pcm_substream * substream the pcm substream instance

int type DMA type (SNDRV_DMA_TYPE_*)

struct device * data DMA type dependent data

size_t size the requested pre-allocation size in bytes

size_t max the max. allowed pre-allocation size

Description

Do pre-allocation for the given DMA buffer type.

void **snd_pcm_lib_preallocate_pages_for_all**(struct snd_pcm * pcm, int type, void * data, size_t size, size_t max)
pre-allocation for continuous memory type (all substreams)

Parameters

struct snd_pcm * pcm the pcm instance

int type DMA type (SNDRV_DMA_TYPE_*)

void * data DMA type dependent data

size_t size the requested pre-allocation size in bytes

size_t max the max. allowed pre-allocation size

Description

Do pre-allocation to all substreams of the given pcm for the specified DMA type.

void **snd_pcm_set_managed_buffer**(struct snd_pcm_substream * substream, int type, struct device * data, size_t size, size_t max)
set up buffer management for a substream

Parameters

struct snd_pcm_substream * substream the pcm substream instance

int type DMA type (SNDRV_DMA_TYPE_*)

struct device * data DMA type dependent data

size_t size the requested pre-allocation size in bytes

size_t max the max. allowed pre-allocation size

Description

Do pre-allocation for the given DMA buffer type, and set the managed buffer allocation mode to the given substream. In this mode, PCM core will allocate a buffer automatically before PCM hw_params ops call, and release the buffer after PCM hw_free ops call as well, so that the driver doesn't need to invoke the allocation and the release explicitly in its callback. When a buffer is actually allocated before the PCM hw_params call, it turns on the runtime buffer_changed flag for drivers changing their h/w parameters accordingly.

void **snd_pcm_set_managed_buffer_all**(struct snd_pcm * pcm, int type, struct device * data, size_t size, size_t max)
set up buffer management for all substreams for all substreams

Parameters

struct snd_pcm * pcm the pcm instance

int type DMA type (SNDRV_DMA_TYPE_*)

struct device * data DMA type dependent data

size_t size the requested pre-allocation size in bytes

size_t max the max. allowed pre-allocation size

Description

Do pre-allocation to all substreams of the given pcm for the specified DMA type and size, and set the managed_buffer_alloc flag to each substream.

int **snd_pcm_lib_malloc_pages**(struct snd_pcm_substream * substream, size_t size)
allocate the DMA buffer

Parameters

struct snd_pcm_substream * substream the substream to allocate the DMA buffer to

size_t size the requested buffer size in bytes

Description

Allocates the DMA buffer on the BUS type given earlier to snd_pcm_lib_preallocate_xxx_pages().

Return

1 if the buffer is changed, 0 if not changed, or a negative code on failure.

int **snd_pcm_lib_free_pages**(struct snd_pcm_substream * substream)
release the allocated DMA buffer.

Parameters

struct snd_pcm_substream * substream the substream to release the DMA buffer

Description

Releases the DMA buffer allocated via `snd_pcm_lib_malloc_pages()`.

Return

Zero if successful, or a negative error code on failure.

int **snd_pcm_lib_free_vmalloc_buffer**(struct snd_pcm_substream * substream)
free vmalloc buffer

Parameters

struct snd_pcm_substream * substream the substream with a buffer allocated by `snd_pcm_lib_alloc_vmalloc_buffer()`

Return

Zero if successful, or a negative error code on failure.

struct page * **snd_pcm_lib_get_vmalloc_page**(struct snd_pcm_substream * substream, unsigned long offset)
map vmalloc buffer offset to page struct

Parameters

struct snd_pcm_substream * substream the substream with a buffer allocated by `snd_pcm_lib_alloc_vmalloc_buffer()`

unsigned long offset offset in the buffer

Description

This function is to be used as the page callback in the PCM ops.

Return

The page struct, or `NULL` on failure.

void **snd_device_initialize**(struct device * dev, struct snd_card * card)
Initialize struct device for sound devices

Parameters

struct device * dev device to initialize

struct snd_card * card card to assign, optional

int **snd_card_new**(struct device * parent, int idx, const char * xid, struct module * module, int extra_size, struct snd_card ** card_ret)
create and initialize a soundcard structure

Parameters

struct device * parent the parent device object

int idx card index (address) [0 …(SNDRV_CARDS-1)]

const char * xid card identification (ASCII string)

struct module * module top level module for locking

int extra_size allocate this extra size after the main soundcard structure

struct snd_card ** card_ret the pointer to store the created card instance

Creates and initializes a soundcard structure.

The function allocates snd_card instance via kzalloc with the given space for the driver to use freely. The allocated struct is stored in the given card_ret pointer.

Return

Zero if successful or a negative error code.

struct snd_card * **snd_card_ref**(int idx)
Get the card object from the index

Parameters

int idx the card index

Description

Returns a card object corresponding to the given index or NULL if not found. Release the object via `snd_card_unref()`.

int **snd_card_disconnect**(struct snd_card * card)
disconnect all APIs from the file-operations (user space)

Parameters

struct snd_card * card soundcard structure

Disconnects all APIs from the file-operations (user space).

Return

Zero, otherwise a negative error code.

Note

The current implementation replaces all active file->f_op with special
dummy file operations (they do nothing except release).

void **snd_card_disconnect_sync**(struct snd_card * card)
disconnect card and wait until files get closed

Parameters

struct snd_card * card card object to disconnect

Description

This calls `snd_card_disconnect()` for disconnecting all belonging components and waits until all pending files get closed. It assures that all accesses from user-space finished so that the driver can release its resources gracefully.

int **snd_card_free_when_closed**(struct snd_card * card)
Disconnect the card, free it later eventually

Parameters

struct snd_card * card soundcard structure

Description

Unlike `snd_card_free()`, this function doesn't try to release the card resource immediately, but tries to disconnect at first. When the card is still in use, the function returns before freeing the resources. The card resources will be freed when the refcount gets to zero.

int **snd_card_free**(struct snd_card * card)
frees given soundcard structure

Parameters

struct snd_card * card soundcard structure

Description

This function releases the soundcard structure and the all assigned devices automatically. That is, you don't have to release the devices by yourself.

This function waits until the all resources are properly released.

Return

Zero. Frees all associated devices and frees the control interface associated to given soundcard.

void **snd_card_set_id**(struct snd_card * card, const char * nid)
set card identification name

Parameters

struct snd_card * card soundcard structure

const char * nid new identification string

This function sets the card identification and checks for name collisions.

int **snd_card_add_dev_attr**(struct snd_card * card, const struct attribute_group * group)
Append a new sysfs attribute group to card

Parameters

struct snd_card * card card instance

const struct attribute_group * group attribute group to append

int **snd_card_register**(struct snd_card * card)
register the soundcard

Parameters

struct snd_card * card soundcard structure

This function registers all the devices assigned to the soundcard. Until calling this, the ALSA control interface is blocked from the external accesses. Thus, you should call this function at the end of the initialization of the card.

Return

Zero otherwise a negative error code if the registration failed.

int **snd_component_add**(struct snd_card * card, const char * component)
add a component string

Parameters

struct snd_card * card soundcard structure

const char * component the component id string

This function adds the component id string to the supported list. The component can be referred from the alsa-lib.

Return

Zero otherwise a negative error code.

int **snd_card_file_add**(struct snd_card * card, struct file * file)
add the file to the file list of the card

Parameters

struct snd_card * card soundcard structure

struct file * file file pointer

This function adds the file to the file linked-list of the card. This linked-list is used to keep tracking the connection state, and to avoid the release of busy resources by hotplug.

Return

zero or a negative error code.

int **snd_card_file_remove**(struct snd_card * card, struct file * file)
remove the file from the file list

Parameters

struct snd_card * card soundcard structure

struct file * file file pointer

This function removes the file formerly added to the card via `snd_card_file_add()` function. If all files are removed and `snd_card_free_when_closed()` was called beforehand, it processes the pending release of resources.

Return

Zero or a negative error code.

int **snd_power_wait**(struct snd_card * card, unsigned int power_state)
wait until the power-state is changed.

Parameters

struct snd_card * card soundcard structure

unsigned int power_state expected power state

Waits until the power-state is changed.

Return

Zero if successful, or a negative error code.

void **snd_dma_program**(unsigned long dma, unsigned long addr, unsigned int size, unsigned short mode)
program an ISA DMA transfer

Parameters

unsigned long dma the dma number

unsigned long addr the physical address of the buffer

unsigned int size the DMA transfer size

unsigned short mode the DMA transfer mode, DMA_MODE_XXX

Description

Programs an ISA DMA transfer for the given buffer.

void **snd_dma_disable**(unsigned long dma)
stop the ISA DMA transfer

Parameters

unsigned long dma the dma number

Description

Stops the ISA DMA transfer.

unsigned int **snd_dma_pointer**(unsigned long dma, unsigned int size)
return the current pointer to DMA transfer buffer in bytes

Parameters

unsigned long dma the dma number

unsigned int size the dma transfer size

Return

The current pointer in DMA transfer buffer in bytes.

void **snd_ctl_notify**(struct snd_card * card, unsigned int mask, struct snd_ctl_elem_id * id)
Send notification to user-space for a control change

Parameters

struct snd_card * card the card to send notification

unsigned int mask the event mask, SNDRV_CTL_EVENT_*

struct snd_ctl_elem_id * id the ctl element id to send notification

Description

This function adds an event record with the given id and mask, appends to the list and wakes up the user-space for notification. This can be called in the atomic context.

struct snd_kcontrol * **snd_ctl_new1**(const struct snd_kcontrol_new * ncontrol, void * private_data)
create a control instance from the template

Parameters

const struct snd_kcontrol_new * ncontrol the initialization record

void * private_data the private data to set

Description

Allocates a new struct snd_kcontrol instance and initialize from the given template. When the access field of ncontrol is 0, it's assumed as READWRITE access. When the count field is 0, it's assumes as one.

Return

The pointer of the newly generated instance, or NULL on failure.

void **snd_ctl_free_one**(struct snd_kcontrol * kcontrol)
release the control instance

Parameters

struct snd_kcontrol * kcontrol the control instance

Description

Releases the control instance created via snd_ctl_new() or snd_ctl_new1(). Don't call this after the control was added to the card.

int **snd_ctl_add**(struct snd_card * card, struct snd_kcontrol * kcontrol)
add the control instance to the card

Parameters

struct snd_card * card the card instance

struct snd_kcontrol * kcontrol the control instance to add

Description

Adds the control instance created via snd_ctl_new() or snd_ctl_new1() to the given card. Assigns also an unique numid used for fast search.

It frees automatically the control which cannot be added.

Return

Zero if successful, or a negative error code on failure.

int **snd_ctl_replace**(struct snd_card * card, struct snd_kcontrol * kcontrol,
bool add_on_replace)
replace the control instance of the card

Parameters

struct snd_card * card the card instance

struct snd_kcontrol * kcontrol the control instance to replace

bool add_on_replace add the control if not already added

Description

Replaces the given control. If the given control does not exist and the add_on_replace flag is set, the control is added. If the control exists, it is destroyed first.

It frees automatically the control which cannot be added or replaced.

Return

Zero if successful, or a negative error code on failure.

int **snd_ctl_remove**(struct snd_card * card, struct snd_kcontrol * kcontrol)
remove the control from the card and release it

Parameters

struct snd_card * card the card instance

struct snd_kcontrol * kcontrol the control instance to remove

Description

Removes the control from the card and then releases the instance. You don't need to call `snd_ctl_free_one()`. You must be in the write lock - down_write(`card->controls_rwsem`).

Return

0 if successful, or a negative error code on failure.

int **snd_ctl_remove_id**(struct snd_card * card, struct snd_ctl_elem_id * id)
remove the control of the given id and release it

Parameters

struct snd_card * card the card instance

struct snd_ctl_elem_id * id the control id to remove

Description

Finds the control instance with the given id, removes it from the card list and releases it.

Return

0 if successful, or a negative error code on failure.

int **snd_ctl_activate_id**(struct snd_card * card, struct snd_ctl_elem_id * id, int active)
activate/inactivate the control of the given id

Parameters

struct snd_card * card the card instance

struct snd_ctl_elem_id * id the control id to activate/inactivate

int active non-zero to activate

Description

Finds the control instance with the given id, and activate or inactivate the control together with notification, if changed. The given ID data is filled with full information.

Return

0 if unchanged, 1 if changed, or a negative error code on failure.

int **snd_ctl_rename_id**(struct snd_card * card, struct snd_ctl_elem_id * src_id, struct snd_ctl_elem_id * dst_id)
replace the id of a control on the card

Parameters

struct snd_card * card the card instance

struct snd_ctl_elem_id * src_id the old id

struct snd_ctl_elem_id * dst_id the new id

Description

Finds the control with the old id from the card, and replaces the id with the new one.

Return

Zero if successful, or a negative error code on failure.

struct snd_kcontrol * **snd_ctl_find_numid**(struct snd_card * card, unsigned int numid)
find the control instance with the given number-id

Parameters

struct snd_card * card the card instance

unsigned int numid the number-id to search

Description

Finds the control instance with the given number-id from the card.

The caller must down card->controls_rwsem before calling this function (if the race condition can happen).

Return

The pointer of the instance if found, or `NULL` if not.

struct snd_kcontrol * **snd_ctl_find_id**(struct snd_card * card, struct snd_ctl_elem_id * id)
find the control instance with the given id

Parameters

struct snd_card * card the card instance

struct snd_ctl_elem_id * id the id to search

Description

Finds the control instance with the given id from the card.

The caller must down card->controls_rwsem before calling this function (if the race condition can happen).

Return

The pointer of the instance if found, or `NULL` if not.

int **snd_ctl_register_ioctl**(snd_kctl_ioctl_func_t fcn)
register the device-specific control-ioctls

Parameters

snd_kctl_ioctl_func_t fcn ioctl callback function

Description

called from each device manager like pcm.c, hwdep.c, etc.

int **snd_ctl_register_ioctl_compat**(snd_kctl_ioctl_func_t fcn)
register the device-specific 32bit compat control-ioctls

Parameters

snd_kctl_ioctl_func_t fcn ioctl callback function

int **snd_ctl_unregister_ioctl**(snd_kctl_ioctl_func_t fcn)
de-register the device-specific control-ioctls

Parameters

snd_kctl_ioctl_func_t fcn ioctl callback function to unregister

int **snd_ctl_unregister_ioctl_compat**(snd_kctl_ioctl_func_t fcn)
de-register the device-specific compat 32bit control-ioctls

Parameters

snd_kctl_ioctl_func_t fcn ioctl callback function to unregister

int **snd_ctl_boolean_mono_info**(struct snd_kcontrol * kcontrol, struct snd_ctl_elem_info * uinfo)
Helper function for a standard boolean info callback with a mono channel

Parameters

struct snd_kcontrol * kcontrol the kcontrol instance

struct snd_ctl_elem_info * uinfo info to store

Description

This is a function that can be used as info callback for a standard boolean control with a single mono channel.

int **snd_ctl_boolean_stereo_info**(struct snd_kcontrol * kcontrol, struct snd_ctl_elem_info * uinfo)
Helper function for a standard boolean info callback with stereo two channels

Parameters

struct snd_kcontrol * kcontrol the kcontrol instance

struct snd_ctl_elem_info * uinfo info to store

Description

This is a function that can be used as info callback for a standard boolean control with stereo two channels.

int **snd_ctl_enum_info**(struct snd_ctl_elem_info * info, unsigned int channels, unsigned int items, const char *const names)
fills the info structure for an enumerated control

Parameters

struct snd_ctl_elem_info * info the structure to be filled

unsigned int channels the number of the control's channels; often one

unsigned int items the number of control values; also the size of **names**

const char *const names an array containing the names of all control values

Description

Sets all required fields in **info** to their appropriate values. If the control's accessibility is not the default (readable and writable), the caller has to fill **info->access**.

Return

Zero.

void **snd_pcm_set_ops**(struct snd_pcm * pcm, int direction, const struct snd_pcm_ops * ops)
set the PCM operators

Parameters

struct snd_pcm * pcm the pcm instance

int direction stream direction, SNDRV_PCM_STREAM_XXX

const struct snd_pcm_ops * ops the operator table

Description

Sets the given PCM operators to the pcm instance.

void **snd_pcm_set_sync**(struct snd_pcm_substream * substream)
set the PCM sync id

Parameters

struct snd_pcm_substream * substream the pcm substream

Description

Sets the PCM sync identifier for the card.

int **snd_interval_refine**(struct snd_interval * i, const struct snd_interval * v)
refine the interval value of configurator

Parameters

struct snd_interval * i the interval value to refine

const struct snd_interval * v the interval value to refer to

Description

Refines the interval value with the reference value. The interval is changed to the range satisfying both intervals. The interval status (min, max, integer, etc.) are evaluated.

Return

Positive if the value is changed, zero if it's not changed, or a negative error code.

int **snd_interval_ratnum**(struct snd_interval * i, unsigned int rats_count, const struct snd_ratnum * rats, unsigned int * nump, unsigned int * denp)
refine the interval value

Parameters

struct snd_interval * i interval to refine

unsigned int rats_count number of ratnum_t

const struct snd_ratnum * rats ratnum_t array

unsigned int * nump pointer to store the resultant numerator

unsigned int * denp pointer to store the resultant denominator

Return

Positive if the value is changed, zero if it's not changed, or a negative error code.

int **snd_interval_list**(struct snd_interval * i, unsigned int count, const unsigned int * list, unsigned int mask)
refine the interval value from the list

Parameters

struct snd_interval * i the interval value to refine

unsigned int count the number of elements in the list

const unsigned int * list the value list

unsigned int mask the bit-mask to evaluate

Description

Refines the interval value from the list. When mask is non-zero, only the elements corresponding to bit 1 are evaluated.

Return

Positive if the value is changed, zero if it's not changed, or a negative error code.

int **snd_interval_ranges**(struct snd_interval * i, unsigned int count, const struct snd_interval * ranges, unsigned int mask)
refine the interval value from the list of ranges

Parameters

struct snd_interval * i the interval value to refine

unsigned int count the number of elements in the list of ranges

const struct snd_interval * ranges the ranges list

unsigned int mask the bit-mask to evaluate

Description

Refines the interval value from the list of ranges. When mask is non-zero, only the elements corresponding to bit 1 are evaluated.

Return

Positive if the value is changed, zero if it's not changed, or a negative error code.

int **snd_pcm_hw_rule_add**(struct snd_pcm_runtime * runtime, unsigned int cond, int var, snd_pcm_hw_rule_func_t func, void * private, int dep, ...)

add the hw-constraint rule

Parameters

struct snd_pcm_runtime * runtime the pcm runtime instance

unsigned int cond condition bits

int var the variable to evaluate

snd_pcm_hw_rule_func_t func the evaluation function

void * private the private data pointer passed to function

int dep the dependent variables

... variable arguments

Return

Zero if successful, or a negative error code on failure.

int **snd_pcm_hw_constraint_mask64**(struct snd_pcm_runtime * runtime, snd_pcm_hw_param_t var, u_int64_t mask)

apply the given bitmap mask constraint

Parameters

struct snd_pcm_runtime * runtime PCM runtime instance

snd_pcm_hw_param_t var hw_params variable to apply the mask

u_int64_t mask the 64bit bitmap mask

Description

Apply the constraint of the given bitmap mask to a 64-bit mask parameter.

Return

Zero if successful, or a negative error code on failure.

int **snd_pcm_hw_constraint_integer**(struct snd_pcm_runtime * runtime, snd_pcm_hw_param_t var)

apply an integer constraint to an interval

Parameters

struct snd_pcm_runtime * runtime PCM runtime instance

snd_pcm_hw_param_t var hw_params variable to apply the integer constraint

Description

Apply the constraint of integer to an interval parameter.

Return

Positive if the value is changed, zero if it's not changed, or a negative error code.

int **snd_pcm_hw_constraint_minmax**(struct snd_pcm_runtime * runtime, snd_pcm_hw_param_t var, unsigned int min, unsigned int max)

apply a min/max range constraint to an interval

Parameters

struct snd_pcm_runtime * runtime PCM runtime instance

snd_pcm_hw_param_t var hw_params variable to apply the range

unsigned int min the minimal value

unsigned int max the maximal value

Description

Apply the min/max range constraint to an interval parameter.

Return

Positive if the value is changed, zero if it's not changed, or a negative error code.

int **snd_pcm_hw_constraint_list**(struct snd_pcm_runtime * runtime, unsigned int cond, snd_pcm_hw_param_t var, const struct snd_pcm_hw_constraint_list * l)

apply a list of constraints to a parameter

Parameters

struct snd_pcm_runtime * runtime PCM runtime instance

unsigned int cond condition bits

snd_pcm_hw_param_t var hw_params variable to apply the list constraint

const struct snd_pcm_hw_constraint_list * l list

Description

Apply the list of constraints to an interval parameter.

Return

Zero if successful, or a negative error code on failure.

int **snd_pcm_hw_constraint_ranges**(struct snd_pcm_runtime * runtime, unsigned int cond, snd_pcm_hw_param_t var, const struct snd_pcm_hw_constraint_ranges * r)

apply list of range constraints to a parameter

Parameters

struct snd_pcm_runtime * runtime PCM runtime instance

unsigned int cond condition bits

snd_pcm_hw_param_t var hw_params variable to apply the list of range constraints

const struct snd_pcm_hw_constraint_ranges * r ranges

Description

Apply the list of range constraints to an interval parameter.

Return

Zero if successful, or a negative error code on failure.

int **snd_pcm_hw_constraint_ratnums**(struct snd_pcm_runtime * runtime, unsigned int cond, snd_pcm_hw_param_t var, const struct snd_pcm_hw_constraint_ratnums * r)

apply ratnums constraint to a parameter

Parameters

struct snd_pcm_runtime * runtime PCM runtime instance

unsigned int cond condition bits

snd_pcm_hw_param_t var hw_params variable to apply the ratnums constraint

const struct snd_pcm_hw_constraint_ratnums * r struct snd_ratnums constriants

Return

Zero if successful, or a negative error code on failure.

int **snd_pcm_hw_constraint_ratdens**(struct snd_pcm_runtime * runtime, unsigned int cond, snd_pcm_hw_param_t var, const struct snd_pcm_hw_constraint_ratdens * r)

apply ratdens constraint to a parameter

Parameters

struct snd_pcm_runtime * runtime PCM runtime instance

unsigned int cond condition bits

snd_pcm_hw_param_t var hw_params variable to apply the ratdens constraint

const struct snd_pcm_hw_constraint_ratdens * r struct snd_ratdens constriants

Return

Zero if successful, or a negative error code on failure.

int **snd_pcm_hw_constraint_msbits**(struct snd_pcm_runtime * runtime, unsigned int cond, unsigned int width, unsigned int msbits)

add a hw constraint msbits rule

Parameters

struct snd_pcm_runtime * runtime PCM runtime instance

unsigned int cond condition bits

unsigned int width sample bits width

unsigned int msbits msbits width

Description

This constraint will set the number of most significant bits (msbits) if a sample format with the specified width has been select. If width is set to 0 the msbits will be set for any sample format with a width larger than the specified msbits.

Return

Zero if successful, or a negative error code on failure.

int **snd_pcm_hw_constraint_step**(struct snd_pcm_runtime * runtime, unsigned int cond, snd_pcm_hw_param_t var, unsigned long step)

add a hw constraint step rule

Parameters

struct snd_pcm_runtime * runtime PCM runtime instance

unsigned int cond condition bits

snd_pcm_hw_param_t var hw_params variable to apply the step constraint

unsigned long step step size

Return

Zero if successful, or a negative error code on failure.

int **snd_pcm_hw_constraint_pow2**(struct snd_pcm_runtime * runtime, unsigned int cond, snd_pcm_hw_param_t var)

add a hw constraint power-of-2 rule

Parameters

struct snd_pcm_runtime * runtime PCM runtime instance

unsigned int cond condition bits

snd_pcm_hw_param_t var hw_params variable to apply the power-of-2 constraint

Return

Zero if successful, or a negative error code on failure.

int **snd_pcm_hw_rule_noresample**(struct snd_pcm_runtime * runtime, unsigned int base_rate)

add a rule to allow disabling hw resampling

Parameters

struct snd_pcm_runtime * runtime PCM runtime instance

unsigned int base_rate the rate at which the hardware does not resample

Return

Zero if successful, or a negative error code on failure.

int **snd_pcm_hw_param_value**(const struct snd_pcm_hw_params * params, snd_pcm_hw_param_t var, int * dir)
return **params** field **var** value

Parameters

const struct snd_pcm_hw_params * params the hw_params instance

snd_pcm_hw_param_t var parameter to retrieve

int * dir pointer to the direction (-1,0,1) or NULL

Return

The value for field **var** if it's fixed in configuration space defined by **params**. -EINVAL otherwise.

int **snd_pcm_hw_param_first**(struct snd_pcm_substream * pcm, struct snd_pcm_hw_params * params, snd_pcm_hw_param_t var, int * dir)
refine config space and return minimum value

Parameters

struct snd_pcm_substream * pcm PCM instance

struct snd_pcm_hw_params * params the hw_params instance

snd_pcm_hw_param_t var parameter to retrieve

int * dir pointer to the direction (-1,0,1) or NULL

Description

Inside configuration space defined by **params** remove from **var** all values > minimum. Reduce configuration space accordingly.

Return

The minimum, or a negative error code on failure.

int **snd_pcm_hw_param_last**(struct snd_pcm_substream * pcm, struct snd_pcm_hw_params * params, snd_pcm_hw_param_t var, int * dir)
refine config space and return maximum value

Parameters

struct snd_pcm_substream * pcm PCM instance

struct snd_pcm_hw_params * params the hw_params instance

snd_pcm_hw_param_t var parameter to retrieve

int * dir pointer to the direction (-1,0,1) or NULL

Description

Inside configuration space defined by **params** remove from **var** all values < maximum. Reduce configuration space accordingly.

Return

The maximum, or a negative error code on failure.

int **snd_pcm_lib_ioctl**(struct snd_pcm_substream * substream, unsigned int cmd, void * arg)
a generic PCM ioctl callback

Parameters

struct snd_pcm_substream * substream the pcm substream instance

unsigned int cmd ioctl command

void * arg ioctl argument

Description

Processes the generic ioctl commands for PCM. Can be passed as the ioctl callback for PCM ops.

Return

Zero if successful, or a negative error code on failure.

void **snd_pcm_period_elapsed**(struct snd_pcm_substream * substream)
update the pcm status for the next period

Parameters

struct snd_pcm_substream * substream the pcm substream instance

Description

This function is called from the interrupt handler when the PCM has processed the period size. It will update the current pointer, wake up sleepers, etc.

Even if more than one periods have elapsed since the last call, you have to call this only once.

int **snd_pcm_add_chmap_ctls**(struct snd_pcm * pcm, int stream, const struct snd_pcm_chmap_elem * chmap, int max_channels, unsigned long private_value, struct snd_pcm_chmap ** info_ret)
create channel-mapping control elements

Parameters

struct snd_pcm * pcm the assigned PCM instance

int stream stream direction

const struct snd_pcm_chmap_elem * chmap channel map elements (for query)

int max_channels the max number of channels for the stream

unsigned long private_value the value passed to each kcontrol's private_value field

struct snd_pcm_chmap ** info_ret store struct snd_pcm_chmap instance if non-NULL

Description

Create channel-mapping control elements assigned to the given PCM stream(s).

Return

Zero if successful, or a negative error value.

int **snd_hwdep_new**(struct snd_card * card, char * id, int device, struct snd_hwdep ** rhwdep)
create a new hwdep instance

Parameters

struct snd_card * card the card instance

char * id the id string

int device the device index (zero-based)

struct snd_hwdep ** rhwdep the pointer to store the new hwdep instance

Description

Creates a new hwdep instance with the given index on the card. The callbacks (hwdep->ops) must be set on the returned instance after this call manually by the caller.

Return

Zero if successful, or a negative error code on failure.

void **snd_pcm_stream_lock**(struct snd_pcm_substream * substream)
Lock the PCM stream

Parameters

struct snd_pcm_substream * substream PCM substream

Description

This locks the PCM stream's spinlock or mutex depending on the nonatomic flag of the given substream. This also takes the global link rw lock (or rw sem), too, for avoiding the race with linked streams.

void **snd_pcm_stream_unlock**(struct snd_pcm_substream * substream)
Unlock the PCM stream

Parameters

struct snd_pcm_substream * substream PCM substream

Description

This unlocks the PCM stream that has been locked via `snd_pcm_stream_lock()`.

void **snd_pcm_stream_lock_irq**(struct snd_pcm_substream * substream)
Lock the PCM stream

Parameters

struct snd_pcm_substream * substream PCM substream

Description

This locks the PCM stream like `snd_pcm_stream_lock()` and disables the local IRQ (only when nonatomic is false). In nonatomic case, this is identical as `snd_pcm_stream_lock()`.

void **snd_pcm_stream_unlock_irq**(struct snd_pcm_substream * substream)
Unlock the PCM stream

Parameters

struct snd_pcm_substream * substream PCM substream

Description

This is a counter-part of `snd_pcm_stream_lock_irq()`.

void **snd_pcm_stream_unlock_irqrestore**(struct snd_pcm_substream * substream, unsigned long flags)
Unlock the PCM stream

Parameters

struct snd_pcm_substream * substream PCM substream

unsigned long flags irq flags

Description

This is a counter-part of `snd_pcm_stream_lock_irqsave()`.

int **snd_pcm_stop**(struct snd_pcm_substream * substream, snd_pcm_state_t state)
try to stop all running streams in the substream group

Parameters

struct snd_pcm_substream * substream the PCM substream instance

snd_pcm_state_t state PCM state after stopping the stream

Description

The state of each stream is then changed to the given state unconditionally.

Return

Zero if successful, or a negative error code.

int **snd_pcm_stop_xrun**(struct snd_pcm_substream * substream)
stop the running streams as XRUN

Parameters

struct snd_pcm_substream * substream the PCM substream instance

Description

This stops the given running substream (and all linked substreams) as XRUN. Unlike `snd_pcm_stop()`, this function takes the substream lock by itself.

Return

Zero if successful, or a negative error code.

int **snd_pcm_suspend_all**(struct snd_pcm * pcm)
trigger SUSPEND to all substreams in the given pcm

Parameters

struct snd_pcm * pcm the PCM instance

Description

After this call, all streams are changed to SUSPENDED state.

Return

Zero if successful (or **pcm** is NULL), or a negative error code.

int **snd_pcm_kernel_ioctl**(struct snd_pcm_substream * substream, unsigned int cmd, void * arg)
Execute PCM ioctl in the kernel-space

Parameters

struct snd_pcm_substream * substream PCM substream

unsigned int cmd IOCTL cmd

void * arg IOCTL argument

Description

The function is provided primarily for OSS layer and USB gadget drivers, and it allows only the limited set of ioctls (hw_params, sw_params, prepare, start, drain, drop, forward).

int **snd_pcm_lib_default_mmap**(struct snd_pcm_substream * substream, struct vm_area_struct * area)
Default PCM data mmap function

Parameters

struct snd_pcm_substream * substream PCM substream

struct vm_area_struct * area VMA

Description

This is the default mmap handler for PCM data. When mmap pcm_ops is NULL, this function is invoked implicitly.

int **snd_pcm_lib_mmap_iomem**(struct snd_pcm_substream * substream, struct vm_area_struct * area)
Default PCM data mmap function for I/O mem

Parameters

struct snd_pcm_substream * substream PCM substream

struct vm_area_struct * area VMA

Description

When your hardware uses the iomapped pages as the hardware buffer and wants to mmap it, pass this function as mmap pcm_ops. Note that this is supposed to work only on limited architectures.

int **snd_dma_alloc_pages**(int type, struct device * device, size_t size, struct snd_dma_buffer * dmab)
allocate the buffer area according to the given type

Parameters

int type the DMA buffer type

struct device * device the device pointer

size_t size the buffer size to allocate

struct snd_dma_buffer * dmab buffer allocation record to store the allocated data

Description

Calls the memory-allocator function for the corresponding buffer type.

Return

Zero if the buffer with the given size is allocated successfully, otherwise a negative value on error.

int **snd_dma_alloc_pages_fallback**(int type, struct device * device, size_t size, struct snd_dma_buffer * dmab)
allocate the buffer area according to the given type with fallback

Parameters

int type the DMA buffer type

struct device * device the device pointer

size_t size the buffer size to allocate

struct snd_dma_buffer * dmab buffer allocation record to store the allocated data

Description

Calls the memory-allocator function for the corresponding buffer type. When no space is left, this function reduces the size and tries to allocate again. The size actually allocated is stored in res_size argument.

Return

Zero if the buffer with the given size is allocated successfully, otherwise a negative value on error.

void **snd_dma_free_pages**(struct snd_dma_buffer * dmab)
release the allocated buffer

Parameters

struct snd_dma_buffer * dmab the buffer allocation record to release

Description

Releases the allocated buffer via `snd_dma_alloc_pages()`.

CHAPTER

SIXTEEN

FRAME BUFFER LIBRARY

The frame buffer drivers depend heavily on four data structures. These structures are declared in include/linux/fb.h. They are fb_info, fb_var_screeninfo, fb_fix_screeninfo and fb_monospecs. The last three can be made available to and from userland.

fb_info defines the current state of a particular video card. Inside fb_info, there exists a fb_ops structure which is a collection of needed functions to make fbdev and fbcon work. fb_info is only visible to the kernel.

fb_var_screeninfo is used to describe the features of a video card that are user defined. With fb_var_screeninfo, things such as depth and the resolution may be defined.

The next structure is fb_fix_screeninfo. This defines the properties of a card that are created when a mode is set and can't be changed otherwise. A good example of this is the start of the frame buffer memory. This "locks" the address of the frame buffer memory, so that it cannot be changed or moved.

The last structure is fb_monospecs. In the old API, there was little importance for fb_monospecs. This allowed for forbidden things such as setting a mode of 800x600 on a fix frequency monitor. With the new API, fb_monospecs prevents such things, and if used correctly, can prevent a monitor from being cooked. fb_monospecs will not be useful until kernels 2.5.x.

16.1 Frame Buffer Memory

int **remove_conflicting_framebuffers**(struct apertures_struct * a, const char * name, bool primary)
remove firmware-configured framebuffers

Parameters

struct apertures_struct * a memory range, users of which are to be removed

const char * name requesting driver name

bool primary also kick vga16fb if present

Description

This function removes framebuffer devices (initialized by firmware/bootloader) which use memory range described by **a**. If **a** is NULL all such devices are removed.

int **remove_conflicting_pci_framebuffers**(struct pci_dev * pdev, const char * name)
remove firmware-configured framebuffers for PCI devices

Parameters

struct pci_dev * pdev PCI device

const char * name requesting driver name

Description

This function removes framebuffer devices (eg. initialized by firmware) using memory range configured for any of **pdev**'s memory bars.

The function assumes that PCI device with shadowed ROM drives a primary display and so kicks out vga16fb.

int **register_framebuffer**(struct fb_info * fb_info)
registers a frame buffer device

Parameters

struct fb_info * fb_info frame buffer info structure

Registers a frame buffer device **fb_info**.

Returns negative errno on error, or zero for success.

void **unregister_framebuffer**(struct fb_info * fb_info)
releases a frame buffer device

Parameters

struct fb_info * fb_info frame buffer info structure

Unregisters a frame buffer device **fb_info**.

Returns negative errno on error, or zero for success.

This function will also notify the framebuffer console to release the driver.

This is meant to be called within a driver's `module_exit()` function. If this is called outside `module_exit()`, ensure that the driver implements fb_open() and fb_release() to check that no processes are using the device.

void **fb_set_suspend**(struct fb_info * info, int state)
low level driver signals suspend

Parameters

struct fb_info * info framebuffer affected

int state 0 = resuming, !=0 = suspending

This is meant to be used by low level drivers to signal suspend/resume to the core & clients. It must be called with the console semaphore held

16.2 Frame Buffer Colormap

void **fb_dealloc_cmap**(struct fb_cmap * cmap)
deallocate a colormap

Parameters

struct fb_cmap * cmap frame buffer colormap structure

Deallocates a colormap that was previously allocated with fb_alloc_cmap().

int **fb_copy_cmap**(const struct fb_cmap * from, struct fb_cmap * to)
copy a colormap

Parameters

const struct fb_cmap * from frame buffer colormap structure

struct fb_cmap * to frame buffer colormap structure

Copy contents of colormap from **from** to **to**.

int **fb_set_cmap**(struct fb_cmap * cmap, struct fb_info * info)
set the colormap

Parameters

struct fb_cmap * cmap frame buffer colormap structure

struct fb_info * info frame buffer info structure

Sets the colormap **cmap** for a screen of device **info**.

Returns negative errno on error, or zero on success.

const struct fb_cmap * **fb_default_cmap**(int len)
get default colormap

Parameters

int len size of palette for a depth

Gets the default colormap for a specific screen depth. **len** is the size of the palette for a particular screen depth.

Returns pointer to a frame buffer colormap structure.

void **fb_invert_cmaps**(void)
invert all defaults colormaps

Parameters

void no arguments

Description

Invert all default colormaps.

16.3 Frame Buffer Video Mode Database

int **fb_try_mode**(struct fb_var_screeninfo * var, struct fb_info * info, const struct fb_videomode * mode, unsigned int bpp)
test a video mode

Parameters

struct fb_var_screeninfo * var frame buffer user defined part of display

struct fb_info * info frame buffer info structure

const struct fb_videomode * mode frame buffer video mode structure

unsigned int bpp color depth in bits per pixel

Tries a video mode to test it's validity for device **info**.

Returns 1 on success.

void **fb_delete_videomode**(const struct fb_videomode * mode, struct list_head * head)
removed videomode entry from modelist

Parameters

const struct fb_videomode * mode videomode to remove

struct list_head * head struct list_head of modelist

NOTES

Will remove all matching mode entries

int **fb_find_mode**(struct fb_var_screeninfo * var, struct fb_info * info, const char * mode_option, const struct fb_videomode * db, unsigned int dbsize, const struct fb_videomode * default_mode, unsigned int default_bpp)
finds a valid video mode

Parameters

struct fb_var_screeninfo * var frame buffer user defined part of display

struct fb_info * info frame buffer info structure

const char * mode_option string video mode to find

const struct fb_videomode * db video mode database

unsigned int dbsize size of **db**

const struct fb_videomode * default_mode default video mode to fall back to

unsigned int default_bpp default color depth in bits per pixel

Description

Finds a suitable video mode, starting with the specified mode in **mode_option** with fallback to **default_mode**. If **default_mode** fails, all modes in the video mode database will be tried.

Valid mode specifiers for **mode_option**:

```
<xres>x<yres>[M][R][-<bpp>][@<refresh>][i][p][m]
```

or

```
<name>[-<bpp>][@<refresh>]
```

with <xres>, <yres>, <bpp> and <refresh> decimal numbers and <name> a string.

If 'M' is present after yres (and before refresh/bpp if present), the function will compute the timings using VESA(tm) Coordinated Video Timings (CVT). If 'R' is present after 'M', will compute with reduced blanking (for flatpanels). If 'i' or 'p' are present, compute interlaced or progressive mode. If 'm' is present, add margins equal to 1.8% of xres rounded down to 8 pixels, and 1.8% of yres. The char 'i', 'p' and 'm' must be after 'M' and 'R'. Example:

```
1024x768MR-8@60m - Reduced blank with margins at 60Hz.
```

Returns zero for failure, 1 if using specified **mode_option**, 2 if using specified **mode_option** with an ignored refresh rate, 3 if default mode is used, 4 if fall back to any valid mode.

NOTE

The passed struct **var** is _not_ cleared! This allows you to supply values for e.g. the grayscale and accel_flags fields.

void **fb_var_to_videomode**(struct fb_videomode * mode, const struct fb_var_screeninfo * var)
convert fb_var_screeninfo to fb_videomode

Parameters

struct fb_videomode * mode pointer to struct fb_videomode

const struct fb_var_screeninfo * var pointer to struct fb_var_screeninfo

void **fb_videomode_to_var**(struct fb_var_screeninfo * var, const struct fb_videomode * mode)
convert fb_videomode to fb_var_screeninfo

Parameters

struct fb_var_screeninfo * var pointer to struct fb_var_screeninfo

const struct fb_videomode * mode pointer to struct fb_videomode

int **fb_mode_is_equal**(const struct fb_videomode * mode1, const struct fb_videomode * mode2)
compare 2 videomodes

Parameters

const struct fb_videomode * mode1 first videomode

const struct fb_videomode * mode2 second videomode

Return

1 if equal, 0 if not

const struct fb_videomode * **fb_find_best_mode**(const struct fb_var_screeninfo * var, struct list_head * head)

find best matching videomode

Parameters

const struct fb_var_screeninfo * var pointer to struct fb_var_screeninfo

struct list_head * head pointer to struct list_head of modelist

Return

struct fb_videomode, NULL if none found

Description

IMPORTANT: This function assumes that all modelist entries in info->modelist are valid.

NOTES

Finds best matching videomode which has an equal or greater dimension than var->xres and var->yres. If more than 1 videomode is found, will return the videomode with the highest refresh rate

const struct fb_videomode * **fb_find_nearest_mode**(const struct fb_videomode * mode, struct list_head * head)

find closest videomode

Parameters

const struct fb_videomode * mode pointer to struct fb_videomode

struct list_head * head pointer to modelist

Description

Finds best matching videomode, smaller or greater in dimension. If more than 1 videomode is found, will return the videomode with the closest refresh rate.

const struct fb_videomode * **fb_match_mode**(const struct fb_var_screeninfo * var, struct list_head * head)

find a videomode which exactly matches the timings in var

Parameters

const struct fb_var_screeninfo * var pointer to struct fb_var_screeninfo

struct list_head * head pointer to struct list_head of modelist

Return

struct fb_videomode, NULL if none found

int **fb_add_videomode**(const struct fb_videomode * mode, struct list_head * head)

adds videomode entry to modelist

Parameters

const struct fb_videomode * mode videomode to add

struct list_head * head struct list_head of modelist

NOTES

Will only add unmatched mode entries

void **fb_destroy_modelist**(struct list_head * head)
destroy modelist

Parameters

struct list_head * head struct list_head of modelist

void **fb_videomode_to_modelist**(const struct fb_videomode * modedb, int num, struct list_head * head)
convert mode array to mode list

Parameters

const struct fb_videomode * modedb array of struct fb_videomode

int num number of entries in array

struct list_head * head struct list_head of modelist

16.4 Frame Buffer Macintosh Video Mode Database

int **mac_vmode_to_var**(int vmode, int cmode, struct fb_var_screeninfo * var)
converts vmode/cmode pair to var structure

Parameters

int vmode MacOS video mode

int cmode MacOS color mode

struct fb_var_screeninfo * var frame buffer video mode structure

Converts a MacOS vmode/cmode pair to a frame buffer video mode structure.

Returns negative errno on error, or zero for success.

int **mac_map_monitor_sense**(int sense)
Convert monitor sense to vmode

Parameters

int sense Macintosh monitor sense number

Converts a Macintosh monitor sense number to a MacOS vmode number.

Returns MacOS vmode video mode number.

int **mac_find_mode**(struct fb_var_screeninfo * var, struct fb_info * info, const char * mode_option, unsigned int default_bpp)
find a video mode

Parameters

struct fb_var_screeninfo * var frame buffer user defined part of display

struct fb_info * info frame buffer info structure

const char * mode_option video mode name (see mac_modedb[])

unsigned int default_bpp default color depth in bits per pixel

Finds a suitable video mode. Tries to set mode specified by **mode_option**. If the name of the wanted mode begins with ‘mac’, the Mac video mode database will be used, otherwise it will fall back to the standard video mode database.

Note

Function marked as __init and can only be used during system boot.

Returns error code from fb_find_mode (see fb_find_mode function).

16.5 Frame Buffer Fonts

Refer to the file lib/fonts/fonts.c for more information.

CHAPTER

SEVENTEEN

VOLTAGE AND CURRENT REGULATOR API

Author Liam Girdwood

Author Mark Brown

17.1 Introduction

This framework is designed to provide a standard kernel interface to control voltage and current regulators.

The intention is to allow systems to dynamically control regulator power output in order to save power and prolong battery life. This applies to both voltage regulators (where voltage output is controllable) and current sinks (where current limit is controllable).

Note that additional (and currently more complete) documentation is available in the Linux kernel source under `Documentation/power/regulator`.

17.1.1 Glossary

The regulator API uses a number of terms which may not be familiar:

Regulator

> Electronic device that supplies power to other devices. Most regulators can enable and disable their output and some can also control their output voltage or current.

Consumer

> Electronic device which consumes power provided by a regulator. These may either be static, requiring only a fixed supply, or dynamic, requiring active management of the regulator at runtime.

Power Domain

> The electronic circuit supplied by a given regulator, including the regulator and all consumer devices. The configuration of the regulator is shared between all the components in the circuit.

Power Management Integrated Circuit (PMIC)

An IC which contains numerous regulators and often also other subsystems. In an embedded system the primary PMIC is often equivalent to a combination of the PSU and southbridge in a desktop system.

17.2 Consumer driver interface

This offers a similar API to the kernel clock framework. Consumer drivers use get and put operations to acquire and release regulators. Functions are provided to enable and disable the regulator and to get and set the runtime parameters of the regulator.

When requesting regulators consumers use symbolic names for their supplies, such as "Vcc", which are mapped into actual regulator devices by the machine interface.

A stub version of this API is provided when the regulator framework is not in use in order to minimise the need to use ifdefs.

17.2.1 Enabling and disabling

The regulator API provides reference counted enabling and disabling of regulators. Consumer devices use the `regulator_enable()` and `regulator_disable()` functions to enable and disable regulators. Calls to the two functions must be balanced.

Note that since multiple consumers may be using a regulator and machine constraints may not allow the regulator to be disabled there is no guarantee that calling `regulator_disable()` will actually cause the supply provided by the regulator to be disabled. Consumer drivers should assume that the regulator may be enabled at all times.

17.2.2 Configuration

Some consumer devices may need to be able to dynamically configure their supplies. For example, MMC drivers may need to select the correct operating voltage for their cards. This may be done while the regulator is enabled or disabled.

The `regulator_set_voltage()` and `regulator_set_current_limit()` functions provide the primary interface for this. Both take ranges of voltages and currents, supporting drivers that do not require a specific value (eg, CPU frequency scaling normally permits the CPU to use a wider range of supply voltages at lower frequencies but does not require that the supply voltage be lowered). Where an exact value is required both minimum and maximum values should be identical.

17.2.3 Callbacks

Callbacks may also be registered for events such as regulation failures.

17.3 Regulator driver interface

Drivers for regulator chips register the regulators with the regulator core, providing operations structures to the core. A notifier interface allows error conditions to be reported to the core.

Registration should be triggered by explicit setup done by the platform, supplying a struct `regulator_init_data` for the regulator containing constraint and supply information.

17.4 Machine interface

This interface provides a way to define how regulators are connected to consumers on a given system and what the valid operating parameters are for the system.

17.4.1 Supplies

Regulator supplies are specified using struct `regulator_consumer_supply`. This is done at driver registration time as part of the machine constraints.

17.4.2 Constraints

As well as defining the connections the machine interface also provides constraints defining the operations that clients are allowed to perform and the parameters that may be set. This is required since generally regulator devices will offer more flexibility than it is safe to use on a given system, for example supporting higher supply voltages than the consumers are rated for.

This is done at driver registration time` by providing a struct `regulation_constraints`.

The constraints may also specify an initial configuration for the regulator in the constraints, which is particularly useful for use with static consumers.

17.5 API reference

Due to limitations of the kernel documentation framework and the existing layout of the source code the entire regulator API is documented here.

struct **pre_voltage_change_data**
Data sent with PRE_VOLTAGE_CHANGE event

Definition

```
struct pre_voltage_change_data {
  unsigned long old_uV;
  unsigned long min_uV;
  unsigned long max_uV;
};
```

Members

old_uV Current voltage before change.

min_uV Min voltage we'll change to.

max_uV Max voltage we'll change to.

struct **regulator_bulk_data**
Data used for bulk regulator operations.

Definition

```
struct regulator_bulk_data {
  const char *supply;
  struct regulator *consumer;
};
```

Members

supply The name of the supply. Initialised by the user before using the bulk regulator APIs.

consumer The regulator consumer for the supply. This will be managed by the bulk API.

Description

The regulator APIs provide a series of regulator_bulk_() API calls as a convenience to consumers which require multiple supplies. This structure is used to manage data for these calls.

struct **regulator_state**
regulator state during low power system states

Definition

```
struct regulator_state {
  int uV;
  int min_uV;
  int max_uV;
  unsigned int mode;
  int enabled;
  bool changeable;
};
```

Members

uV Default operating voltage during suspend, it can be adjusted among <min_uV, max_uV>.

min_uV Minimum suspend voltage may be set.

max_uV Maximum suspend voltage may be set.

mode Operating mode during suspend.

enabled operations during suspend. - DO_NOTHING_IN_SUSPEND - DISABLE_IN_SUSPEND - ENABLE_IN_SUSPEND

changeable Is this state can be switched between enabled/disabled,

Description

This describes a regulators state during a system wide low power state. One of enabled or disabled must be set for the configuration to be applied.

struct **regulation_constraints**
regulator operating constraints.

Definition

```
struct regulation_constraints {
  const char *name;
  int min_uV;
  int max_uV;
  int uV_offset;
  int min_uA;
  int max_uA;
  int ilim_uA;
  int system_load;
  u32 *max_spread;
  int max_uV_step;
  unsigned int valid_modes_mask;
  unsigned int valid_ops_mask;
  int input_uV;
  struct regulator_state state_disk;
  struct regulator_state state_mem;
  struct regulator_state state_standby;
  suspend_state_t initial_state;
  unsigned int initial_mode;
  unsigned int ramp_delay;
  unsigned int settling_time;
  unsigned int settling_time_up;
  unsigned int settling_time_down;
  unsigned int enable_time;
  unsigned int active_discharge;
  unsigned always_on:1;
  unsigned boot_on:1;
  unsigned apply_uV:1;
  unsigned ramp_disable:1;
  unsigned soft_start:1;
  unsigned pull_down:1;
  unsigned over_current_protection:1;
};
```

Members

name Descriptive name for the constraints, used for display purposes.

min_uV Smallest voltage consumers may set.

max_uV Largest voltage consumers may set.

uV_offset Offset applied to voltages from consumer to compensate for voltage drops.

min_uA Smallest current consumers may set.

max_uA Largest current consumers may set.

ilim_uA Maximum input current.

system_load Load that isn't captured by any consumer requests.

max_spread Max possible spread between coupled regulators

valid_modes_mask Mask of modes which may be configured by consumers.

valid_ops_mask Operations which may be performed by consumers.

input_uV Input voltage for regulator when supplied by another regulator.

state_disk State for regulator when system is suspended in disk mode.

state_mem State for regulator when system is suspended in mem mode.

state_standby State for regulator when system is suspended in standby mode.

initial_state Suspend state to set by default.

initial_mode Mode to set at startup.

ramp_delay Time to settle down after voltage change (unit: uV/us)

settling_time Time to settle down after voltage change when voltage change is non-linear (unit: microseconds).

settling_time_up Time to settle down after voltage increase when voltage change is non-linear (unit: microseconds).

settling_time_down Time to settle down after voltage decrease when voltage change is non-linear (unit: microseconds).

enable_time Turn-on time of the rails (unit: microseconds)

active_discharge Enable/disable active discharge. The enum regulator_active_discharge values are used for initialisation.

always_on Set if the regulator should never be disabled.

boot_on Set if the regulator is enabled when the system is initially started. If the regulator is not enabled by the hardware or bootloader then it will be enabled when the constraints are applied.

apply_uV Apply the voltage constraint when initialising.

ramp_disable Disable ramp delay when initialising or when setting voltage.

soft_start Enable soft start so that voltage ramps slowly.

pull_down Enable pull down when regulator is disabled.

over_current_protection Auto disable on over current event.

Description

This struct describes regulator and board/machine specific constraints.

struct **regulator_consumer_supply**
supply -> device mapping

Definition

```
struct regulator_consumer_supply {
  const char *dev_name;
  const char *supply;
};
```

Members

dev_name Result of dev_name() for the consumer.

supply Name for the supply.

Description

This maps a supply name to a device. Use of dev_name allows support for buses which make struct device available late such as I2C.

struct **regulator_init_data**
regulator platform initialisation data.

Definition

```
struct regulator_init_data {
  const char *supply_regulator;
  struct regulation_constraints constraints;
  int num_consumer_supplies;
  struct regulator_consumer_supply *consumer_supplies;
  int (*regulator_init)(void *driver_data);
  void *driver_data;
};
```

Members

supply_regulator Parent regulator. Specified using the regulator name as it appears in the name field in sysfs, which can be explicitly set using the constraints field 'name'.

constraints Constraints. These must be specified for the regulator to be usable.

num_consumer_supplies Number of consumer device supplies.

consumer_supplies Consumer device supply configuration.

regulator_init Callback invoked when the regulator has been registered.

driver_data Data passed to regulator_init.

Description

Initialisation constraints, our supply and consumers supplies.

struct **regulator_ops**
regulator operations.

Definition

```
struct regulator_ops {
  int (*list_voltage) (struct regulator_dev *, unsigned selector);
  int (*set_voltage) (struct regulator_dev *, int min_uV, int max_uV,␣
↪unsigned *selector);
  int (*map_voltage)(struct regulator_dev *, int min_uV, int max_uV);
  int (*set_voltage_sel) (struct regulator_dev *, unsigned selector);
  int (*get_voltage) (struct regulator_dev *);
  int (*get_voltage_sel) (struct regulator_dev *);
  int (*set_current_limit) (struct regulator_dev *, int min_uA, int max_
↪uA);
  int (*get_current_limit) (struct regulator_dev *);
  int (*set_input_current_limit) (struct regulator_dev *, int lim_uA);
  int (*set_over_current_protection) (struct regulator_dev *);
  int (*set_active_discharge) (struct regulator_dev *, bool enable);
  int (*enable) (struct regulator_dev *);
  int (*disable) (struct regulator_dev *);
  int (*is_enabled) (struct regulator_dev *);
  int (*set_mode) (struct regulator_dev *, unsigned int mode);
  unsigned int (*get_mode) (struct regulator_dev *);
  int (*get_error_flags)(struct regulator_dev *, unsigned int *flags);
  int (*enable_time) (struct regulator_dev *);
  int (*set_ramp_delay) (struct regulator_dev *, int ramp_delay);
  int (*set_voltage_time) (struct regulator_dev *, int old_uV, int new_uV);
  int (*set_voltage_time_sel) (struct regulator_dev *,unsigned int old_
↪selector, unsigned int new_selector);
  int (*set_soft_start) (struct regulator_dev *);
  int (*get_status)(struct regulator_dev *);
  unsigned int (*get_optimum_mode) (struct regulator_dev *, int input_uV,␣
↪int output_uV, int load_uA);
  int (*set_load)(struct regulator_dev *, int load_uA);
  int (*set_bypass)(struct regulator_dev *dev, bool enable);
  int (*get_bypass)(struct regulator_dev *dev, bool *enable);
  int (*set_suspend_voltage) (struct regulator_dev *, int uV);
  int (*set_suspend_enable) (struct regulator_dev *);
  int (*set_suspend_disable) (struct regulator_dev *);
  int (*set_suspend_mode) (struct regulator_dev *, unsigned int mode);
  int (*resume)(struct regulator_dev *rdev);
  int (*set_pull_down) (struct regulator_dev *);
};
```

Members

list_voltage Return one of the supported voltages, in microvolts; zero if the selector indicates a voltage that is unusable on this system; or negative errno. Selectors range from zero to one less than regulator_desc.n_voltages. Voltages may be reported in any order.

set_voltage Set the voltage for the regulator within the range specified. The driver should select the voltage closest to min_uV.

map_voltage Convert a voltage into a selector

set_voltage_sel Set the voltage for the regulator using the specified selector.

get_voltage Return the currently configured voltage for the regulator; return -ENOTRECOVERABLE if regulator can't be read at bootup and hasn't been set yet.

get_voltage_sel Return the currently configured voltage selector for the regulator; return -ENOTRECOVERABLE if regulator can't be read at bootup and hasn't been set yet.

set_current_limit Configure a limit for a current-limited regulator. The driver should select the current closest to max_uA.

get_current_limit Get the configured limit for a current-limited regulator.

set_input_current_limit Configure an input limit.

set_over_current_protection Support capability of automatically shutting down when detecting an over current event.

set_active_discharge Set active discharge enable/disable of regulators.

enable Configure the regulator as enabled.

disable Configure the regulator as disabled.

is_enabled Return 1 if the regulator is enabled, 0 if not. May also return negative errno.

set_mode Set the configured operating mode for the regulator.

get_mode Get the configured operating mode for the regulator.

get_error_flags Get the current error(s) for the regulator.

enable_time Time taken for the regulator voltage output voltage to stabilise after being enabled, in microseconds.

set_ramp_delay Set the ramp delay for the regulator. The driver should select ramp delay equal to or less than(closest) ramp_delay.

set_voltage_time Time taken for the regulator voltage output voltage to stabilise after being set to a new value, in microseconds. The function receives the from and to voltage as input, it should return the worst case.

set_voltage_time_sel Time taken for the regulator voltage output voltage to stabilise after being set to a new value, in microseconds. The function receives the from and to voltage selector as input, it should return the worst case.

set_soft_start Enable soft start for the regulator.

get_status Return actual (not as-configured) status of regulator, as a REGULATOR_STATUS value (or negative errno)

get_optimum_mode Get the most efficient operating mode for the regulator when running with the specified parameters.

set_load Set the load for the regulator.

set_bypass Set the regulator in bypass mode.

get_bypass Get the regulator bypass mode state.

set_suspend_voltage Set the voltage for the regulator when the system is suspended.

set_suspend_enable Mark the regulator as enabled when the system is suspended.

set_suspend_disable Mark the regulator as disabled when the system is suspended.

set_suspend_mode Set the operating mode for the regulator when the system is suspended.

set_pull_down Configure the regulator to pull down when the regulator is disabled.

Description

This struct describes regulator operations which can be implemented by regulator chip drivers.

struct **regulator_desc**
Static regulator descriptor

Definition

```
struct regulator_desc {
  const char *name;
  const char *supply_name;
  const char *of_match;
  const char *regulators_node;
  int (*of_parse_cb)(struct device_node *,const struct regulator_desc *,␣
↪struct regulator_config *);
  int id;
  unsigned int continuous_voltage_range:1;
  unsigned n_voltages;
  unsigned int n_current_limits;
  const struct regulator_ops *ops;
  int irq;
  enum regulator_type type;
  struct module *owner;
  unsigned int min_uV;
  unsigned int uV_step;
  unsigned int linear_min_sel;
  int fixed_uV;
  unsigned int ramp_delay;
  int min_dropout_uV;
  const struct linear_range *linear_ranges;
  const unsigned int *linear_range_selectors;
  int n_linear_ranges;
  const unsigned int *volt_table;
  const unsigned int *curr_table;
  unsigned int vsel_range_reg;
  unsigned int vsel_range_mask;
  unsigned int vsel_reg;
  unsigned int vsel_mask;
  unsigned int vsel_step;
  unsigned int csel_reg;
  unsigned int csel_mask;
  unsigned int apply_reg;
  unsigned int apply_bit;
  unsigned int enable_reg;
  unsigned int enable_mask;
  unsigned int enable_val;
  unsigned int disable_val;
```

(continues on next page)

(continued from previous page)

```
  bool enable_is_inverted;

  unsigned int bypass_mask;
  unsigned int bypass_val_on;
  unsigned int bypass_val_off;
  unsigned int active_discharge_on;
  unsigned int active_discharge_off;
  unsigned int active_discharge_mask;
  unsigned int active_discharge_reg;
  unsigned int soft_start_reg;
  unsigned int soft_start_mask;
  unsigned int soft_start_val_on;
  unsigned int pull_down_reg;
  unsigned int pull_down_mask;
  unsigned int pull_down_val_on;
  unsigned int enable_time;
  unsigned int off_on_delay;
  unsigned int (*of_map_mode)(unsigned int mode);
};
```

Members

name Identifying name for the regulator.

supply_name Identifying the regulator supply

of_match Name used to identify regulator in DT.

regulators_node Name of node containing regulator definitions in DT.

of_parse_cb Optional callback called only if of_match is present. Will be called for each regulator parsed from DT, during init_data parsing. The regulator_config passed as argument to the callback will be a copy of config passed to regulator_register, valid only for this particular call. Callback may freely change the config but it cannot store it for later usage. Callback should return 0 on success or negative ERRNO indicating failure.

id Numerical identifier for the regulator.

continuous_voltage_range Indicates if the regulator can set any voltage within constrains range.

n_voltages Number of selectors available for ops.list_voltage().

n_current_limits Number of selectors available for current limits

ops Regulator operations table.

irq Interrupt number for the regulator.

type Indicates if the regulator is a voltage or current regulator.

owner Module providing the regulator, used for refcounting.

min_uV Voltage given by the lowest selector (if linear mapping)

uV_step Voltage increase with each selector (if linear mapping)

linear_min_sel Minimal selector for starting linear mapping

fixed_uV Fixed voltage of rails.

ramp_delay Time to settle down after voltage change (unit: uV/us)

min_dropout_uV The minimum dropout voltage this regulator can handle

linear_ranges A constant table of possible voltage ranges.

linear_range_selectors A constant table of voltage range selectors. If pickable ranges are used each range must have corresponding selector here.

n_linear_ranges Number of entries in the **linear_ranges** (and in linear_range_selectors if used) table(s).

volt_table Voltage mapping table (if table based mapping)

curr_table Current limit mapping table (if table based mapping)

vsel_range_reg Register for range selector when using pickable ranges and `regulator_map_*_voltage_*_pickable` functions.

vsel_range_mask Mask for register bitfield used for range selector

vsel_reg Register for selector when using `regulator_map_*_voltage_*`

vsel_mask Mask for register bitfield used for selector

vsel_step Specify the resolution of selector stepping when setting voltage. If 0, then no stepping is done (requested selector is set directly), if >0 then the regulator API will ramp the voltage up/down gradually each time increasing/decreasing the selector by the specified step value.

csel_reg Register for current limit selector using regmap set_current_limit

csel_mask Mask for register bitfield used for current limit selector

apply_reg Register for initiate voltage change on the output when using regulator_set_voltage_sel_regmap

apply_bit Register bitfield used for initiate voltage change on the output when using regulator_set_voltage_sel_regmap

enable_reg Register for control when using regmap enable/disable ops

enable_mask Mask for control when using regmap enable/disable ops

enable_val Enabling value for control when using regmap enable/disable ops

disable_val Disabling value for control when using regmap enable/disable ops

enable_is_inverted A flag to indicate set enable_mask bits to disable when using regulator_enable_regmap and friends APIs.

bypass_reg Register for control when using regmap set_bypass

bypass_mask Mask for control when using regmap set_bypass

bypass_val_on Enabling value for control when using regmap set_bypass

bypass_val_off Disabling value for control when using regmap set_bypass

active_discharge_on Disabling value for control when using regmap set_active_discharge

active_discharge_off Enabling value for control when using regmap set_active_discharge

active_discharge_mask Mask for control when using regmap set_active_discharge

active_discharge_reg Register for control when using regmap set_active_discharge

soft_start_reg Register for control when using regmap set_soft_start

soft_start_mask Mask for control when using regmap set_soft_start

soft_start_val_on Enabling value for control when using regmap set_soft_start

pull_down_reg Register for control when using regmap set_pull_down

pull_down_mask Mask for control when using regmap set_pull_down

pull_down_val_on Enabling value for control when using regmap set_pull_down

enable_time Time taken for initial enable of regulator (in uS).

off_on_delay guard time (in uS), before re-enabling a regulator

of_map_mode Maps a hardware mode defined in a DeviceTree to a standard mode

Description

Each regulator registered with the core is described with a structure of this type and a struct regulator_config. This structure contains the non-varying parts of the regulator description.

struct **regulator_config**
Dynamic regulator descriptor

Definition

```
struct regulator_config {
  struct device *dev;
  const struct regulator_init_data *init_data;
  void *driver_data;
  struct device_node *of_node;
  struct regmap *regmap;
  struct gpio_desc *ena_gpiod;
};
```

Members

dev struct device for the regulator

init_data platform provided init data, passed through by driver

driver_data private regulator data

of_node OpenFirmware node to parse for device tree bindings (may be NULL).

regmap regmap to use for core regmap helpers if dev_get_regmap() is insufficient.

ena_gpiod GPIO controlling regulator enable.

Description

Each regulator registered with the core is described with a structure of this type and a struct regulator_desc. This structure contains the runtime variable parts of the regulator description.

void **regulator_lock**(struct regulator_dev * rdev)
lock a single regulator

Parameters

struct regulator_dev * rdev regulator source

Description

This function can be called many times by one task on a single regulator and its mutex will be locked only once. If a task, which is calling this function is other than the one, which initially locked the mutex, it will wait on mutex.

void **regulator_unlock**(struct regulator_dev * rdev)
unlock a single regulator

Parameters

struct regulator_dev * rdev regulator_source

Description

This function unlocks the mutex when the reference counter reaches 0.

struct regulator * **regulator_get**(struct device * dev, const char * id)
lookup and obtain a reference to a regulator.

Parameters

struct device * dev device for regulator "consumer"

const char * id Supply name or regulator ID.

Description

Returns a struct regulator corresponding to the regulator producer, or IS_ERR() condition containing errno.

Use of supply names configured via regulator_set_device_supply() is strongly encouraged. It is recommended that the supply name used should match the name used for the supply and/or the relevant device pins in the datasheet.

struct regulator * **regulator_get_exclusive**(struct device * dev, const char * id)
obtain exclusive access to a regulator.

Parameters

struct device * dev device for regulator "consumer"

const char * id Supply name or regulator ID.

Description

Returns a struct regulator corresponding to the regulator producer, or IS_ERR() condition containing errno. Other consumers will be unable to obtain this regulator while this reference is held and the use count for the regulator will be initialised to reflect the current state of the regulator.

This is intended for use by consumers which cannot tolerate shared use of the regulator such as those which need to force the regulator off for correct operation of the hardware they are controlling.

Use of supply names configured via regulator_set_device_supply() is strongly encouraged. It is recommended that the supply name used should match the name used for the supply and/or the relevant device pins in the datasheet.

struct regulator * **regulator_get_optional**(struct device * dev, const char * id)
obtain optional access to a regulator.

Parameters

struct device * dev device for regulator "consumer"

const char * id Supply name or regulator ID.

Description

Returns a struct regulator corresponding to the regulator producer, or IS_ERR() condition containing errno.

This is intended for use by consumers for devices which can have some supplies unconnected in normal use, such as some MMC devices. It can allow the regulator core to provide stub supplies for other supplies requested using normal `regulator_get()` calls without disrupting the operation of drivers that can handle absent supplies.

Use of supply names configured via regulator_set_device_supply() is strongly encouraged. It is recommended that the supply name used should match the name used for the supply and/or the relevant device pins in the datasheet.

void **regulator_put**(struct regulator * regulator)
"free" the regulator source

Parameters

struct regulator * regulator regulator source

Note

drivers must ensure that all regulator_enable calls made on this regulator source are balanced by regulator_disable calls prior to calling this function.

int **regulator_register_supply_alias**(struct device * dev, const char * id, struct device * alias_dev, const char * alias_id)
Provide device alias for supply lookup

Parameters

struct device * dev device that will be given as the regulator "consumer"

const char * id Supply name or regulator ID

struct device * alias_dev device that should be used to lookup the supply

const char * alias_id Supply name or regulator ID that should be used to lookup the supply

Description

All lookups for id on dev will instead be conducted for alias_id on alias_dev.

void **regulator_unregister_supply_alias**(struct device * dev, const char * id)
Remove device alias

Parameters

struct device * dev device that will be given as the regulator "consumer"

const char * id Supply name or regulator ID

Description

Remove a lookup alias if one exists for id on dev.

int **regulator_bulk_register_supply_alias**(struct device * dev, const char *const * id, struct device * alias_dev, const char *const * alias_id, int num_id)
register multiple aliases

Parameters

struct device * dev device that will be given as the regulator "consumer"

const char *const * id List of supply names or regulator IDs

struct device * alias_dev device that should be used to lookup the supply

const char *const * alias_id List of supply names or regulator IDs that should be used to lookup the supply

int num_id Number of aliases to register

Description

return 0 on success, an errno on failure.

This helper function allows drivers to register several supply aliases in one operation. If any of the aliases cannot be registered any aliases that were registered will be removed before returning to the caller.

void **regulator_bulk_unregister_supply_alias**(struct device * dev, const char *const * id, int num_id)
unregister multiple aliases

Parameters

struct device * dev device that will be given as the regulator "consumer"

const char *const * id List of supply names or regulator IDs

int num_id Number of aliases to unregister

Description

This helper function allows drivers to unregister several supply aliases in one operation.

int **regulator_enable**(struct regulator * regulator)
enable regulator output

Parameters

struct regulator * regulator regulator source

Description

Request that the regulator be enabled with the regulator output at the predefined voltage or current value. Calls to `regulator_enable()` must be balanced with calls to `regulator_disable()`.

NOTE

the output value can be set by other drivers, boot loader or may be hardwired in the regulator.

int **regulator_disable**(struct regulator * regulator)
disable regulator output

Parameters

struct regulator * regulator regulator source

Description

Disable the regulator output voltage or current. Calls to `regulator_enable()` must be balanced with calls to `regulator_disable()`.

NOTE

this will only disable the regulator output if no other consumer devices have it enabled, the regulator device supports disabling and machine constraints permit this operation.

int **regulator_force_disable**(struct regulator * regulator)
force disable regulator output

Parameters

struct regulator * regulator regulator source

Description

Forcibly disable the regulator output voltage or current.

NOTE

this will disable the regulator output even if other consumer devices have it enabled. This should be used for situations when device damage will likely occur if the regulator is not disabled (e.g. over temp).

int **regulator_disable_deferred**(struct regulator * regulator, int ms)
disable regulator output with delay

Parameters

struct regulator * regulator regulator source

int ms milliseconds until the regulator is disabled

Description

Execute `regulator_disable()` on the regulator after a delay. This is intended for use with devices that require some time to quiesce.

NOTE

this will only disable the regulator output if no other consumer devices have it enabled, the regulator device supports disabling and machine constraints permit this operation.

int **regulator_is_enabled**(struct regulator * regulator)
is the regulator output enabled

Parameters

struct regulator * regulator regulator source

Description

Returns positive if the regulator driver backing the source/client has requested that the device be enabled, zero if it hasn't, else a negative errno code.

Note that the device backing this regulator handle can have multiple users, so it might be enabled even if `regulator_enable()` was never called for this particular source.

int **regulator_count_voltages**(struct regulator * regulator)
count `regulator_list_voltage()` selectors

Parameters

struct regulator * regulator regulator source

Description

Returns number of selectors, or negative errno. Selectors are numbered starting at zero, and typically correspond to bitfields in hardware registers.

int **regulator_list_voltage**(struct regulator * regulator, unsigned selector)
enumerate supported voltages

Parameters

struct regulator * regulator regulator source

unsigned selector identify voltage to list

Context

can sleep

Description

Returns a voltage that can be passed to **regulator_set_voltage()**, zero if this selector code can't be used on this system, or a negative errno.

int **regulator_get_hardware_vsel_register**(struct regulator * regulator, unsigned * vsel_reg, unsigned * vsel_mask)
get the HW voltage selector register

Parameters

struct regulator * regulator regulator source

unsigned * vsel_reg voltage selector register, output parameter

unsigned * vsel_mask mask for voltage selector bitfield, output parameter

Description

Returns the hardware register offset and bitmask used for setting the regulator voltage. This might be useful when configuring voltage-scaling hardware or firmware that can make I2C requests behind the kernel's back, for example.

On success, the output parameters **vsel_reg** and **vsel_mask** are filled in and 0 is returned, otherwise a negative errno is returned.

int **regulator_list_hardware_vsel**(struct regulator * regulator, unsigned selector)
get the HW-specific register value for a selector

Parameters

struct regulator * regulator regulator source

unsigned selector identify voltage to list

Description

Converts the selector to a hardware-specific voltage selector that can be directly written to the regulator registers. The address of the voltage register can be determined by calling **regulator_get_hardware_vsel_register**.

On error a negative errno is returned.

unsigned int **regulator_get_linear_step**(struct regulator * regulator)
return the voltage step size between VSEL values

Parameters

struct regulator * regulator regulator source

Description

Returns the voltage step size between VSEL values for linear regulators, or return 0 if the regulator isn't a linear regulator.

int **regulator_is_supported_voltage**(struct regulator * regulator, int min_uV, int max_uV)
check if a voltage range can be supported

Parameters

struct regulator * regulator Regulator to check.

int min_uV Minimum required voltage in uV.

int max_uV Maximum required voltage in uV.

Description

Returns a boolean.

int **regulator_set_voltage**(struct regulator * regulator, int min_uV, int max_uV)
set regulator output voltage

Parameters

struct regulator * regulator regulator source

int min_uV Minimum required voltage in uV

int max_uV Maximum acceptable voltage in uV

Description

Sets a voltage regulator to the desired output voltage. This can be set during any regulator state. IOW, regulator can be disabled or enabled.

If the regulator is enabled then the voltage will change to the new value immediately otherwise if the regulator is disabled the regulator will output at the new voltage when enabled.

NOTE

If the regulator is shared between several devices then the lowest request voltage that meets the system constraints will be used. Regulator system constraints must be set for this regulator before calling this function otherwise this call will fail.

int **regulator_set_voltage_time**(struct regulator * regulator, int old_uV, int new_uV)

get raise/fall time

Parameters

struct regulator * regulator regulator source

int old_uV starting voltage in microvolts

int new_uV target voltage in microvolts

Description

Provided with the starting and ending voltage, this function attempts to calculate the time in microseconds required to rise or fall to this new voltage.

int **regulator_set_voltage_time_sel**(struct regulator_dev * rdev, unsigned int old_selector, unsigned int new_selector)

get raise/fall time

Parameters

struct regulator_dev * rdev regulator source device

unsigned int old_selector selector for starting voltage

unsigned int new_selector selector for target voltage

Description

Provided with the starting and target voltage selectors, this function returns time in microseconds required to rise or fall to this new voltage

Drivers providing ramp_delay in regulation_constraints can use this as their set_voltage_time_sel() operation.

int **regulator_sync_voltage**(struct regulator * regulator)

re-apply last regulator output voltage

Parameters

struct regulator * regulator regulator source

Description

Re-apply the last configured voltage. This is intended to be used where some external control source the consumer is cooperating with has caused the configured voltage to change.

int **regulator_get_voltage**(struct regulator * regulator)
get regulator output voltage

Parameters

struct regulator * regulator regulator source

Description

This returns the current regulator voltage in uV.

NOTE

If the regulator is disabled it will return the voltage value. This function should not be used to determine regulator state.

int **regulator_set_current_limit**(struct regulator * regulator, int min_uA,
int max_uA)
set regulator output current limit

Parameters

struct regulator * regulator regulator source

int min_uA Minimum supported current in uA

int max_uA Maximum supported current in uA

Description

Sets current sink to the desired output current. This can be set during any regulator state. IOW, regulator can be disabled or enabled.

If the regulator is enabled then the current will change to the new value immediately otherwise if the regulator is disabled the regulator will output at the new current when enabled.

NOTE

Regulator system constraints must be set for this regulator before calling this function otherwise this call will fail.

int **regulator_get_current_limit**(struct regulator * regulator)
get regulator output current

Parameters

struct regulator * regulator regulator source

Description

This returns the current supplied by the specified current sink in uA.

NOTE

If the regulator is disabled it will return the current value. This function should not be used to determine regulator state.

int **regulator_set_mode**(struct regulator * regulator, unsigned int mode)
set regulator operating mode

Parameters

struct regulator * regulator regulator source

unsigned int mode operating mode - one of the REGULATOR_MODE constants

Description

Set regulator operating mode to increase regulator efficiency or improve regulation performance.

NOTE

Regulator system constraints must be set for this regulator before calling this function otherwise this call will fail.

unsigned int **regulator_get_mode**(struct regulator * regulator)
get regulator operating mode

Parameters

struct regulator * regulator regulator source

Description

Get the current regulator operating mode.

int **regulator_get_error_flags**(struct regulator * regulator, unsigned int * flags)
get regulator error information

Parameters

struct regulator * regulator regulator source

unsigned int * flags pointer to store error flags

Description

Get the current regulator error information.

int **regulator_set_load**(struct regulator * regulator, int uA_load)
set regulator load

Parameters

struct regulator * regulator regulator source

int uA_load load current

Description

Notifies the regulator core of a new device load. This is then used by DRMS (if enabled by constraints) to set the most efficient regulator operating mode for the new regulator loading.

Consumer devices notify their supply regulator of the maximum power they will require (can be taken from device datasheet in the power consumption tables) when they change operational status and hence power state. Examples of operational state changes that can affect power consumption are :-

o Device is opened / closed. o Device I/O is about to begin or has just finished. o Device is idling in between work.

This information is also exported via sysfs to userspace.

DRMS will sum the total requested load on the regulator and change to the most efficient operating mode if platform constraints allow.

If a regulator is an always-on regulator then an individual consumer's load will still be removed if that consumer is fully disabled.

On error a negative errno is returned.

NOTE

when a regulator consumer requests to have a regulator disabled then any load that consumer requested no longer counts toward the total requested load. If the regulator is re-enabled then the previously requested load will start counting again.

int **regulator_allow_bypass**(struct regulator * regulator, bool enable)
allow the regulator to go into bypass mode

Parameters

struct regulator * regulator Regulator to configure

bool enable enable or disable bypass mode

Description

Allow the regulator to go into bypass mode if all other consumers for the regulator also enable bypass mode and the machine constraints allow this. Bypass mode means that the regulator is simply passing the input directly to the output with no regulation.

int **regulator_register_notifier**(struct regulator * regulator, struct notifier_block * nb)
register regulator event notifier

Parameters

struct regulator * regulator regulator source

struct notifier_block * nb notifier block

Description

Register notifier block to receive regulator events.

int **regulator_unregister_notifier**(struct regulator * regulator, struct notifier_block * nb)
unregister regulator event notifier

Parameters

struct regulator * regulator regulator source

struct notifier_block * nb notifier block

Description

Unregister regulator event notifier block.

int **regulator_bulk_get**(struct device * dev, int num_consumers, struct regulator_bulk_data * consumers)
get multiple regulator consumers

Parameters

struct device * dev Device to supply

int num_consumers Number of consumers to register

struct regulator_bulk_data * consumers Configuration of consumers; clients are stored here.

Description

return 0 on success, an errno on failure.

This helper function allows drivers to get several regulator consumers in one operation. If any of the regulators cannot be acquired then any regulators that were allocated will be freed before returning to the caller.

int **regulator_bulk_enable**(int num_consumers, struct regulator_bulk_data * consumers)
enable multiple regulator consumers

Parameters

int num_consumers Number of consumers

struct regulator_bulk_data * consumers Consumer data; clients are stored here. **return** 0 on success, an errno on failure

Description

This convenience API allows consumers to enable multiple regulator clients in a single API call. If any consumers cannot be enabled then any others that were enabled will be disabled again prior to return.

int **regulator_bulk_disable**(int num_consumers, struct regulator_bulk_data * consumers)
disable multiple regulator consumers

Parameters

int num_consumers Number of consumers

struct regulator_bulk_data * consumers Consumer data; clients are stored here. **return** 0 on success, an errno on failure

Description

This convenience API allows consumers to disable multiple regulator clients in a single API call. If any consumers cannot be disabled then any others that were disabled will be enabled again prior to return.

int **regulator_bulk_force_disable**(int num_consumers, struct regulator_bulk_data * consumers)
force disable multiple regulator consumers

Parameters

int num_consumers Number of consumers

struct regulator_bulk_data * consumers Consumer data; clients are stored here. **return** 0 on success, an errno on failure

Description

This convenience API allows consumers to forcibly disable multiple regulator clients in a single API call.

NOTE

This should be used for situations when device damage will likely occur if the regulators are not disabled (e.g. over temp). Although regulator_force_disable function call for some consumers can return error numbers, the function is called for all consumers.

void **regulator_bulk_free**(int num_consumers, struct regulator_bulk_data * consumers)
free multiple regulator consumers

Parameters

int num_consumers Number of consumers

struct regulator_bulk_data * consumers Consumer data; clients are stored here.

Description

This convenience API allows consumers to free multiple regulator clients in a single API call.

int **regulator_notifier_call_chain**(struct regulator_dev * rdev, unsigned long event, void * data)
call regulator event notifier

Parameters

struct regulator_dev * rdev regulator source

unsigned long event notifier block

void * data callback-specific data.

Description

Called by regulator drivers to notify clients a regulator event has occurred. We also notify regulator clients downstream. Note lock must be held by caller.

int **regulator_mode_to_status**(unsigned int mode)
convert a regulator mode into a status

Parameters

unsigned int mode Mode to convert

Description

Convert a regulator mode into a status.

struct regulator_dev * **regulator_register**(const struct regulator_desc * regulator_desc, const struct regulator_config * cfg)
register regulator

Parameters

const struct regulator_desc * regulator_desc regulator to register

const struct regulator_config * cfg runtime configuration for regulator

Description

Called by regulator drivers to register a regulator. Returns a valid pointer to struct regulator_dev on success or an ERR_PTR() on error.

void **regulator_unregister**(struct regulator_dev * rdev)
unregister regulator

Parameters

struct regulator_dev * rdev regulator to unregister

Description

Called by regulator drivers to unregister a regulator.

void **regulator_has_full_constraints**(void)
the system has fully specified constraints

Parameters

void no arguments

Description

Calling this function will cause the regulator API to disable all regulators which have a zero use count and don’t have an always_on constraint in a late_initcall.

The intention is that this will become the default behaviour in a future kernel release so users are encouraged to use this facility now.

void * **rdev_get_drvdata**(struct regulator_dev * rdev)
get rdev regulator driver data

Parameters

struct regulator_dev * rdev regulator

Description

Get rdev regulator driver private data. This call can be used in the regulator driver context.

void * **regulator_get_drvdata**(struct regulator * regulator)
get regulator driver data

Parameters

struct regulator * regulator regulator

Description

Get regulator driver private data. This call can be used in the consumer driver context when non API regulator specific functions need to be called.

void **regulator_set_drvdata**(struct regulator * regulator, void * data)
set regulator driver data

Parameters

struct regulator * regulator regulator

void * data data

int **rdev_get_id**(struct regulator_dev * rdev)
get regulator ID

Parameters

struct regulator_dev * rdev regulator

CHAPTER

EIGHTEEN

INDUSTRIAL I/O

Contents:

18.1 Introduction

The main purpose of the Industrial I/O subsystem (IIO) is to provide support for devices that in some sense perform either analog-to-digital conversion (ADC) or digital-to-analog conversion (DAC) or both. The aim is to fill the gap between the somewhat similar hwmon and input subsystems. Hwmon is directed at low sample rate sensors used to monitor and control the system itself, like fan speed control or temperature measurement. Input is, as its name suggests, focused on human interaction input devices (keyboard, mouse, touchscreen). In some cases there is considerable overlap between these and IIO.

Devices that fall into this category include:

- analog to digital converters (ADCs)
- accelerometers
- capacitance to digital converters (CDCs)
- digital to analog converters (DACs)
- gyroscopes
- inertial measurement units (IMUs)
- color and light sensors
- magnetometers
- pressure sensors
- proximity sensors
- temperature sensors

Usually these sensors are connected via SPI or I2C. A common use case of the sensors devices is to have combined functionality (e.g. light plus proximity sensor).

18.2 Core elements

The Industrial I/O core offers both a unified framework for writing drivers for many different types of embedded sensors and a standard interface to user space applications manipulating sensors. The implementation can be found under `drivers/iio/industrialio-*`

18.2.1 Industrial I/O Devices

- struct `iio_dev` - industrial I/O device
- `iio_device_alloc()` - allocate an `iio_dev` from a driver
- `iio_device_free()` - free an `iio_dev` from a driver
- `iio_device_register()` - register a device with the IIO subsystem
- `iio_device_unregister()` - unregister a device from the IIO subsystem

An IIO device usually corresponds to a single hardware sensor and it provides all the information needed by a driver handling a device. Let's first have a look at the functionality embedded in an IIO device then we will show how a device driver makes use of an IIO device.

There are two ways for a user space application to interact with an IIO driver.

1. `/sys/bus/iio/iio:deviceX/`, this represents a hardware sensor and groups together the data channels of the same chip.
2. `/dev/iio:deviceX`, character device node interface used for buffered data transfer and for events information retrieval.

A typical IIO driver will register itself as an I2C or SPI driver and will create two routines, probe and remove.

At probe:

1. Call `iio_device_alloc()`, which allocates memory for an IIO device.
2. Initialize IIO device fields with driver specific information (e.g. device name, device channels).
3. Call `iio_device_register()`, this registers the device with the IIO core. After this call the device is ready to accept requests from user space applications.

At remove, we free the resources allocated in probe in reverse order:

1. `iio_device_unregister()`, unregister the device from the IIO core.
2. `iio_device_free()`, free the memory allocated for the IIO device.

IIO device sysfs interface

Attributes are sysfs files used to expose chip info and also allowing applications to set various configuration parameters. For device with index X, attributes can be found under /sys/bus/iio/iio:deviceX/ directory. Common attributes are:

- `name`, description of the physical chip.
- `dev`, shows the major:minor pair associated with `/dev/iio:deviceX` node.
- `sampling_frequency_available`, available discrete set of sampling frequency values for device.
- Available standard attributes for IIO devices are described in the `Documentation/ABI/testing/sysfs-bus-iio` file in the Linux kernel sources.

IIO device channels

struct `iio_chan_spec` - specification of a single channel

An IIO device channel is a representation of a data channel. An IIO device can have one or multiple channels. For example:

- a thermometer sensor has one channel representing the temperature measurement.
- a light sensor with two channels indicating the measurements in the visible and infrared spectrum.
- an accelerometer can have up to 3 channels representing acceleration on X, Y and Z axes.

An IIO channel is described by the struct `iio_chan_spec`. A thermometer driver for the temperature sensor in the example above would have to describe its channel as follows:

```
static const struct iio_chan_spec temp_channel[] = {
     {
          .type = IIO_TEMP,
          .info_mask_separate = BIT(IIO_CHAN_INFO_PROCESSED),
     },
};
```

Channel sysfs attributes exposed to userspace are specified in the form of bitmasks. Depending on their shared info, attributes can be set in one of the following masks:

- **info_mask_separate**, attributes will be specific to this channel
- **info_mask_shared_by_type**, attributes are shared by all channels of the same type
- **info_mask_shared_by_dir**, attributes are shared by all channels of the same direction
- **info_mask_shared_by_all**, attributes are shared by all channels

When there are multiple data channels per channel type we have two ways to distinguish between them:

- set **.modified** field of `iio_chan_spec` to 1. Modifiers are specified using **.channel2** field of the same `iio_chan_spec` structure and are used to indicate a physically unique characteristic of the channel such as its direction or spectral response. For example, a light sensor can have two channels, one for infrared light and one for both infrared and visible light.
- set **.indexed** field of `iio_chan_spec` to 1. In this case the channel is simply another instance with an index specified by the **.channel** field.

Here is how we can make use of the channel's modifiers:

```
static const struct iio_chan_spec light_channels[] = {
        {
                .type = IIO_INTENSITY,
                .modified = 1,
                .channel2 = IIO_MOD_LIGHT_IR,
                .info_mask_separate = BIT(IIO_CHAN_INFO_RAW),
                .info_mask_shared = BIT(IIO_CHAN_INFO_SAMP_FREQ),
        },
        {
                .type = IIO_INTENSITY,
                .modified = 1,
                .channel2 = IIO_MOD_LIGHT_BOTH,
                .info_mask_separate = BIT(IIO_CHAN_INFO_RAW),
                .info_mask_shared = BIT(IIO_CHAN_INFO_SAMP_FREQ),
        },
        {
                .type = IIO_LIGHT,
                .info_mask_separate = BIT(IIO_CHAN_INFO_PROCESSED),
                .info_mask_shared = BIT(IIO_CHAN_INFO_SAMP_FREQ),
        },
   }
```

This channel's definition will generate two separate sysfs files for raw data retrieval:

- `/sys/bus/iio/iio:deviceX/in_intensity_ir_raw`
- `/sys/bus/iio/iio:deviceX/in_intensity_both_raw`

one file for processed data:

- `/sys/bus/iio/iio:deviceX/in_illuminance_input`

and one shared sysfs file for sampling frequency:

- `/sys/bus/iio/iio:deviceX/sampling_frequency`.

Here is how we can make use of the channel's indexing:

```
static const struct iio_chan_spec light_channels[] = {
        {
                .type = IIO_VOLTAGE,
                .indexed = 1,
                .channel = 0,
                .info_mask_separate = BIT(IIO_CHAN_INFO_RAW),
```

(continues on next page)

(continued from previous page)

```
        },
        {
                .type = IIO_VOLTAGE,
                .indexed = 1,
                .channel = 1,
                .info_mask_separate = BIT(IIO_CHAN_INFO_RAW),
        },
}
```

This will generate two separate attributes files for raw data retrieval:

- `/sys/bus/iio/devices/iio:deviceX/in_voltage0_raw`, representing voltage measurement for channel 0.
- `/sys/bus/iio/devices/iio:deviceX/in_voltage1_raw`, representing voltage measurement for channel 1.

More details

struct **iio_chan_spec_ext_info**
Extended channel info attribute

Definition

```
struct iio_chan_spec_ext_info {
  const char *name;
  enum iio_shared_by shared;
  ssize_t (*read)(struct iio_dev *, uintptr_t private, struct iio_chan_
↪spec const *, char *buf);
  ssize_t (*write)(struct iio_dev *, uintptr_t private,struct iio_chan_
↪spec const *, const char *buf, size_t len);
  uintptr_t private;
};
```

Members

name Info attribute name

shared Whether this attribute is shared between all channels.

read Read callback for this info attribute, may be NULL.

write Write callback for this info attribute, may be NULL.

private Data private to the driver.

struct **iio_enum**
Enum channel info attribute

Definition

```
struct iio_enum {
  const char * const *items;
  unsigned int num_items;
  int (*set)(struct iio_dev *, const struct iio_chan_spec *, unsigned int);
  int (*get)(struct iio_dev *, const struct iio_chan_spec *);
};
```

Members

items An array of strings.

num_items Length of the item array.

set Set callback function, may be NULL.

get Get callback function, may be NULL.

Description

The iio_enum struct can be used to implement enum style channel attributes. Enum style attributes are those which have a set of strings which map to unsigned integer values. The IIO enum helper code takes care of mapping between value and string as well as generating a "_available" file which contains a list of all available items. The set callback will be called when the attribute is updated. The last parameter is the index to the newly activated item. The get callback will be used to query the currently active item and is supposed to return the index for it.

IIO_ENUM(_name, _shared, _e)
Initialize enum extended channel attribute

Parameters

_name Attribute name

_shared Whether the attribute is shared between all channels

_e Pointer to an iio_enum struct

Description

This should usually be used together with `IIO_ENUM_AVAILABLE()`

IIO_ENUM_AVAILABLE(_name, _e)
Initialize enum available extended channel attribute

Parameters

_name Attribute name ("_available" will be appended to the name)

_e Pointer to an iio_enum struct

Description

Creates a read only attribute which lists all the available enum items in a space separated list. This should usually be used together with `IIO_ENUM()`

struct **iio_mount_matrix**
iio mounting matrix

Definition

```
struct iio_mount_matrix {
  const char *rotation[9];
};
```

Members

rotation 3 dimensional space rotation matrix defining sensor alignment with main hardware

IIO_MOUNT_MATRIX(_shared, _get)
Initialize mount matrix extended channel attribute

Parameters

_shared Whether the attribute is shared between all channels

_get Pointer to an iio_get_mount_matrix_t accessor

struct **iio_event_spec**
specification for a channel event

Definition

```
struct iio_event_spec {
  enum iio_event_type type;
  enum iio_event_direction dir;
  unsigned long mask_separate;
  unsigned long mask_shared_by_type;
  unsigned long mask_shared_by_dir;
  unsigned long mask_shared_by_all;
};
```

Members

type Type of the event

dir Direction of the event

mask_separate Bit mask of enum iio_event_info values. Attributes set in this mask will be registered per channel.

mask_shared_by_type Bit mask of enum iio_event_info values. Attributes set in this mask will be shared by channel type.

mask_shared_by_dir Bit mask of enum iio_event_info values. Attributes set in this mask will be shared by channel type and direction.

mask_shared_by_all Bit mask of enum iio_event_info values. Attributes set in this mask will be shared by all channels.

struct **iio_chan_spec**
specification of a single channel

Definition

```
struct iio_chan_spec {
  enum iio_chan_type      type;
  int channel;
  int channel2;
  unsigned long           address;
  int scan_index;
  struct {
    char sign;
    u8 realbits;

Members

type What type of measurement is the channel making.

channel What number do we wish to assign the channel.

channel2 If there is a second number for a differential channel then this is it. If modified is set then the value here specifies the modifier.

address Driver specific identifier.

scan_index Monotonic index to give ordering in scans when read from a buffer.

scan_type struct describing the scan type

scan_type.sign ‘s’ or ‘u’ to specify signed or unsigned

scan_type.realbits Number of valid bits of data

scan_type.storagebits Realbits + padding

scan_type.shift Shift right by this before masking out realbits.

scan_type.repeat Number of times real/storage bits repeats. When the repeat element is more than 1, then the type element in sysfs will show a repeat value. Otherwise, the number of repetitions is omitted.

scan_type.endianness little or big endian

info_mask_separate What information is to be exported that is specific to this channel.

info_mask_separate_available What availability information is to be exported that is specific to this channel.

info_mask_shared_by_type What information is to be exported that is shared by all channels of the same type.

info_mask_shared_by_type_available What availability information is to be exported that is shared by all channels of the same type.

info_mask_shared_by_dir What information is to be exported that is shared by all channels of the same direction.

info_mask_shared_by_dir_available What availability information is to be exported that is shared by all channels of the same direction.

info_mask_shared_by_all What information is to be exported that is shared by all channels.

info_mask_shared_by_all_available What availability information is to be exported that is shared by all channels.

event_spec Array of events which should be registered for this channel.

num_event_specs Size of the event_spec array.

ext_info Array of extended info attributes for this channel. The array is NULL terminated, the last element should have its name field set to NULL.

extend_name Allows labeling of channel attributes with an informative name. Note this has no effect codes etc, unlike modifiers.

datasheet_name A name used in in-kernel mapping of channels. It should correspond to the first name that the channel is referred to by in the datasheet (e.g. IND), or the nearest possible compound name (e.g. IND-INC).

modified Does a modifier apply to this channel. What these are depends on the channel type. Modifier is set in channel2. Examples are IIO_MOD_X for axial sensors about the 'x' axis.

indexed Specify the channel has a numerical index. If not, the channel index number will be suppressed for sysfs attributes but not for event codes.

output Channel is output.

differential Channel is differential.

bool **iio_channel_has_info**(const struct iio_chan_spec * chan, enum iio_chan_info_enum type)
Checks whether a channel supports a info attribute

Parameters

const struct iio_chan_spec * chan The channel to be queried

enum iio_chan_info_enum type Type of the info attribute to be checked

Description

Returns true if the channels supports reporting values for the given info attribute type, false otherwise.

bool **iio_channel_has_available**(const struct iio_chan_spec * chan, enum iio_chan_info_enum type)
Checks if a channel has an available attribute

Parameters

const struct iio_chan_spec * chan The channel to be queried

enum iio_chan_info_enum type Type of the available attribute to be checked

Description

Returns true if the channel supports reporting available values for the given attribute type, false otherwise.

struct **iio_info**
constant information about device

Definition

```
struct iio_info {

  int (*of_xlate)(struct iio_dev *indio_dev, const struct of_phandle_args␣
↪*iiospec);
  int (*hwfifo_set_watermark)(struct iio_dev *indio_dev, unsigned val);
  int (*hwfifo_flush_to_buffer)(struct iio_dev *indio_dev, unsigned count);
};
```

Members

event_attrs event control attributes

attrs general purpose device attributes

read_raw function to request a value from the device. mask specifies which value. Note 0 means a reading of the channel in question. Return value will specify the type of value returned by the device. val and val2 will contain the elements making up the returned value.

read_raw_multi function to return values from the device. mask specifies which value. Note 0 means a reading of the channel in question. Return value will

specify the type of value returned by the device. vals pointer contain the elements making up the returned value. max_len specifies maximum number of elements vals pointer can contain. val_len is used to return length of valid elements in vals.

read_avail function to return the available values from the device. mask specifies which value. Note 0 means the available values for the channel in question. Return value specifies if a IIO_AVAIL_LIST or a IIO_AVAIL_RANGE is returned in vals. The type of the vals are returned in type and the number of vals is returned in length. For ranges, there are always three vals returned; min, step and max. For lists, all possible values are enumerated.

write_raw function to write a value to the device. Parameters are the same as for read_raw.

write_raw_get_fmt callback function to query the expected format/precision. If not set by the driver, write_raw returns IIO_VAL_INT_PLUS_MICRO.

read_event_config find out if the event is enabled.

write_event_config set if the event is enabled.

read_event_value read a configuration value associated with the event.

write_event_value write a configuration value for the event.

validate_trigger function to validate the trigger when the current trigger gets changed.

update_scan_mode function to configure device and scan buffer when channels have changed

debugfs_reg_access function to read or write register value of device

of_xlate function pointer to obtain channel specifier index. When #iio-cells is greater than '0', the driver could provide a custom of_xlate function that reads the args and returns the appropriate index in registered IIO channels array.

hwfifo_set_watermark function pointer to set the current hardware fifo watermark level; see hwfifo_* entries in Documentation/ABI/testing/sysfs-bus-iio for details on how the hardware fifo operates

hwfifo_flush_to_buffer function pointer to flush the samples stored in the hardware fifo to the device buffer. The driver should not flush more than count samples. The function must return the number of samples flushed, 0 if no samples were flushed or a negative integer if no samples were flushed and there was an error.

struct **iio_buffer_setup_ops**
buffer setup related callbacks

Definition

```
struct iio_buffer_setup_ops {
  int (*preenable)(struct iio_dev *);
  int (*postenable)(struct iio_dev *);
  int (*predisable)(struct iio_dev *);

Members

id [INTERN] used to identify device internally

driver_module [INTERN] used to make it harder to undercut users

modes [DRIVER] operating modes supported by device

currentmode [DRIVER] current operating mode

dev [DRIVER] device structure, should be assigned a parent and owner

event_interface [INTERN] event chrdevs associated with interrupt lines

buffer [DRIVER] any buffer present

buffer_list [INTERN] list of all buffers currently attached

scan_bytes [INTERN] num bytes captured to be fed to buffer demux

mlock [INTERN] lock used to prevent simultaneous device state changes

available_scan_masks [DRIVER] optional array of allowed bitmasks

masklength [INTERN] the length of the mask established from channels

active_scan_mask [INTERN] union of all scan masks requested by buffers

scan_timestamp [INTERN] set if any buffers have requested timestamp

scan_index_timestamp [INTERN] cache of the index to the timestamp

trig [INTERN] current device trigger (buffer modes)

trig_readonly [INTERN] mark the current trigger immutable

pollfunc [DRIVER] function run on trigger being received

pollfunc_event [DRIVER] function run on events trigger being received

channels [DRIVER] channel specification structure table

num_channels [DRIVER] number of channels specified in **channels**.

channel_attr_list [INTERN] keep track of automatically created channel attributes

chan_attr_group [INTERN] group for all attrs in base directory

name [DRIVER] name of the device.

label [DRIVER] unique name to identify which device this is

info [DRIVER] callbacks and constant info from driver

clock_id [INTERN] timestamping clock posix identifier

info_exist_lock [INTERN] lock to prevent use during removal

setup_ops [DRIVER] callbacks to call before and after buffer enable/disable

chrdev [INTERN] associated character device

groups [INTERN] attribute groups

groupcounter [INTERN] index of next attribute group

flags [INTERN] file ops related flags including busy flag.

debugfs_dentry [INTERN] device specific debugfs dentry.

cached_reg_addr [INTERN] cached register address for debugfs reads.

iio_device_register(indio_dev)
register a device with the IIO subsystem

Parameters

indio_dev Device structure filled by the device driver

devm_iio_device_register(dev, indio_dev)
Resource-managed `iio_device_register()`

Parameters

dev Device to allocate iio_dev for

indio_dev Device structure filled by the device driver

Description

Managed iio_device_register. The IIO device registered with this function is automatically unregistered on driver detach. This function calls `iio_device_register()` internally. Refer to that function for more information.

Return

0 on success, negative error number on failure.

void **iio_device_put**(struct iio_dev * indio_dev)
reference counted deallocation of struct device

Parameters

struct iio_dev * indio_dev IIO device structure containing the device

clockid_t **iio_device_get_clock**(const struct iio_dev * indio_dev)
Retrieve current timestamping clock for the device

Parameters

const struct iio_dev * indio_dev IIO device structure containing the device

struct iio_dev * **dev_to_iio_dev**(struct device * dev)
Get IIO device struct from a device struct

Parameters

struct device * dev The device embedded in the IIO device

Note

The device must be a IIO device, otherwise the result is undefined.

struct iio_dev * **iio_device_get**(struct iio_dev * indio_dev)
increment reference count for the device

Parameters

struct iio_dev * indio_dev IIO device structure

Return

The passed IIO device

void **iio_device_set_drvdata**(struct iio_dev * indio_dev, void * data)
Set device driver data

Parameters

struct iio_dev * indio_dev IIO device structure

void * data Driver specific data

Description

Allows to attach an arbitrary pointer to an IIO device, which can later be retrieved by `iio_device_get_drvdata()`.

void * **iio_device_get_drvdata**(struct iio_dev * indio_dev)
Get device driver data

Parameters

struct iio_dev * indio_dev IIO device structure

Description

Returns the data previously set with `iio_device_set_drvdata()`

bool **iio_buffer_enabled**(struct iio_dev * indio_dev)
helper function to test if the buffer is enabled

Parameters

struct iio_dev * indio_dev IIO device structure for device

struct dentry * **iio_get_debugfs_dentry**(struct iio_dev * indio_dev)
helper function to get the debugfs_dentry

Parameters

struct iio_dev * indio_dev IIO device structure for device

IIO_DEGREE_TO_RAD(deg)
Convert degree to rad

Parameters

deg A value in degree

Description

Returns the given value converted from degree to rad

IIO_RAD_TO_DEGREE(rad)
Convert rad to degree

Parameters

rad A value in rad

Description

Returns the given value converted from rad to degree

IIO_G_TO_M_S_2(g)
Convert g to meter / second**2

Parameters

g A value in g

Description

Returns the given value converted from g to meter / second**2

IIO_M_S_2_TO_G(ms2)
Convert meter / second**2 to g

Parameters

ms2 A value in meter / second**2

Description

Returns the given value converted from meter / second**2 to g

int **iio_device_set_clock**(struct iio_dev * indio_dev, clockid_t clock_id)
Set current timestamping clock for the device

Parameters

struct iio_dev * indio_dev IIO device structure containing the device

clockid_t clock_id timestamping clock posix identifier to set.

s64 **iio_get_time_ns**(const struct iio_dev * indio_dev)
utility function to get a time stamp for events etc

Parameters

const struct iio_dev * indio_dev device

unsigned int **iio_get_time_res**(const struct iio_dev * indio_dev)
utility function to get time stamp clock resolution in nano seconds.

Parameters

const struct iio_dev * indio_dev device

int **iio_read_mount_matrix**(struct device * dev, const char * propname,
struct iio_mount_matrix * matrix)
retrieve iio device mounting matrix from device “mount-matrix” property

Parameters

struct device * dev device the mounting matrix property is assigned to

const char * propname device specific mounting matrix property name

struct iio_mount_matrix * matrix where to store retrieved matrix

Description

If device is assigned no mounting matrix property, a default 3x3 identity matrix will be filled in.

Return

0 if success, or a negative error code on failure.

ssize_t **iio_format_value**(char * buf, unsigned int type, int size, int * vals)
Formats a IIO value into its string representation

Parameters

char * buf The buffer to which the formatted value gets written which is assumed to be big enough (i.e. PAGE_SIZE).

unsigned int type One of the IIO_VAL_* constants. This decides how the val and val2 parameters are formatted.

int size Number of IIO value entries contained in vals

int * vals Pointer to the values, exact meaning depends on the type parameter.

Return

0 by default, a negative number on failure or the total number of characters written for a type that belongs to the IIO_VAL_* constant.

int **iio_str_to_fixpoint**(const char * str, int fract_mult, int * integer, int * fract)
Parse a fixed-point number from a string

Parameters

const char * str The string to parse

int fract_mult Multiplier for the first decimal place, should be a power of 10

int * integer The integer part of the number

int * fract The fractional part of the number

Description

Returns 0 on success, or a negative error code if the string could not be parsed.

struct iio_dev * **iio_device_alloc**(int sizeof_priv)
allocate an iio_dev from a driver

Parameters

int sizeof_priv Space to allocate for private structure.

void **iio_device_free**(struct iio_dev * dev)
free an iio_dev from a driver

Parameters

struct iio_dev * dev the iio_dev associated with the device

struct iio_dev * **devm_iio_device_alloc**(struct device * dev, int sizeof_priv)
Resource-managed `iio_device_alloc()`

Parameters

struct device * dev Device to allocate iio_dev for

int sizeof_priv Space to allocate for private structure.

Description

Managed iio_device_alloc. iio_dev allocated with this function is automatically freed on driver detach.

Return

Pointer to allocated iio_dev on success, NULL on failure.

void **iio_device_unregister**(struct iio_dev * indio_dev)
unregister a device from the IIO subsystem

Parameters

struct iio_dev * indio_dev Device structure representing the device.

int **iio_device_claim_direct_mode**(struct iio_dev * indio_dev)
Keep device in direct mode

Parameters

struct iio_dev * indio_dev the iio_dev associated with the device

Description

If the device is in direct mode it is guaranteed to stay that way until `iio_device_release_direct_mode()` is called.

Use with `iio_device_release_direct_mode()`

Return

0 on success, -EBUSY on failure

void **iio_device_release_direct_mode**(struct iio_dev * indio_dev)
releases claim on direct mode

Parameters

struct iio_dev * indio_dev the iio_dev associated with the device

Description

Release the claim. Device is no longer guaranteed to stay in direct mode.

Use with `iio_device_claim_direct_mode()`

18.3 Buffers

- struct `iio_buffer` —general buffer structure
- `iio_validate_scan_mask_onehot()` —Validates that exactly one channel is selected
- `iio_buffer_get()` —Grab a reference to the buffer
- `iio_buffer_put()` —Release the reference to the buffer

The Industrial I/O core offers a way for continuous data capture based on a trigger source. Multiple data channels can be read at once from `/dev/iio:deviceX` character device node, thus reducing the CPU load.

18.3.1 IIO buffer sysfs interface

An IIO buffer has an associated attributes directory under `/sys/bus/iio/iio:deviceX/buffer/*`. Here are some of the existing attributes:

- `length`, the total number of data samples (capacity) that can be stored by the buffer.
- `enable`, activate buffer capture.

18.3.2 IIO buffer setup

The meta information associated with a channel reading placed in a buffer is called a scan element. The important bits configuring scan elements are exposed to userspace applications via the `/sys/bus/iio/iio:deviceX/scan_elements/*` directory. This file contains attributes of the following form:

- `enable`, used for enabling a channel. If and only if its attribute is non zero, then a triggered capture will contain data samples for this channel.
- `type`, description of the scan element data storage within the buffer and hence the form in which it is read from user space. Format is [be|le]:[s|u]bits/storagebitsXrepeat[>>shift] . * be or le, specifies big or little endian. * s or u, specifies if signed (2's complement) or unsigned. * bits, is the number of valid data bits. * storagebits, is the number of bits (after padding) that it occupies in the buffer. * shift, if specified, is the shift that needs to be applied prior to masking out unused bits. * repeat, specifies the number of bits/storagebits repetitions. When the repeat element is 0 or 1, then the repeat value is omitted.

For example, a driver for a 3-axis accelerometer with 12 bit resolution where data is stored in two 8-bits registers as follows:

```
  7   6   5   4   3   2   1   0
+---+---+---+---+---+---+---+---+
|D3 |D2 |D1 |D0 | X | X | X | X | (LOW byte, address 0x06)
+---+---+---+---+---+---+---+---+

  7   6   5   4   3   2   1   0
+---+---+---+---+---+---+---+---+
|D11|D10|D9 |D8 |D7 |D6 |D5 |D4 | (HIGH byte, address 0x07)
+---+---+---+---+---+---+---+---+
```

will have the following scan element type for each axis:

```
$ cat /sys/bus/iio/devices/iio:device0/scan_elements/in_accel_y_type
le:s12/16>>4
```

A user space application will interpret data samples read from the buffer as two byte little endian signed data, that needs a 4 bits right shift before masking out the 12 valid bits of data.

For implementing buffer support a driver should initialize the following fields in iio_chan_spec definition:

```
struct iio_chan_spec {
/* other members */
        int scan_index
        struct {
                char sign;
                u8 realbits;
                u8 storagebits;
                u8 shift;
                u8 repeat;
                enum iio_endian endianness;
               } scan_type;
       };
```

The driver implementing the accelerometer described above will have the following channel definition:

```
struct struct iio_chan_spec accel_channels[] = {
        {
                .type = IIO_ACCEL,
                .modified = 1,
                .channel2 = IIO_MOD_X,
                /* other stuff here */
                .scan_index = 0,
                .scan_type = {
                        .sign = 's',
                        .realbits = 12,
                        .storagebits = 16,
                        .shift = 4,
                        .endianness = IIO_LE,
                },
        }
        /* similar for Y (with channel2 = IIO_MOD_Y, scan_index = 1)
         * and Z (with channel2 = IIO_MOD_Z, scan_index = 2) axis
         */
 }
```

Here **scan_index** defines the order in which the enabled channels are placed inside the buffer. Channels with a lower **scan_index** will be placed before channels with a higher index. Each channel needs to have a unique **scan_index**.

Setting **scan_index** to -1 can be used to indicate that the specific channel does not support buffered capture. In this case no entries will be created for the channel in the scan_elements directory.

18.3.3 More details

int **iio_push_to_buffers_with_timestamp**(struct iio_dev * indio_dev, void * data, int64_t timestamp)
push data and timestamp to buffers

Parameters

struct iio_dev * indio_dev iio_dev structure for device.

void * data sample data

int64_t timestamp timestamp for the sample data

Description

Pushes data to the IIO device's buffers. If timestamps are enabled for the device the function will store the supplied timestamp as the last element in the sample data buffer before pushing it to the device buffers. The sample data buffer needs to be large enough to hold the additional timestamp (usually the buffer should be indio->scan_bytes bytes large).

Returns 0 on success, a negative error code otherwise.

void **iio_buffer_set_attrs**(struct iio_buffer * buffer, const struct attribute ** attrs)
Set buffer specific attributes

Parameters

struct iio_buffer * buffer The buffer for which we are setting attributes

const struct attribute ** attrs Pointer to a null terminated list of pointers to attributes

bool **iio_validate_scan_mask_onehot**(struct iio_dev * indio_dev, const unsigned long * mask)
Validates that exactly one channel is selected

Parameters

struct iio_dev * indio_dev the iio device

const unsigned long * mask scan mask to be checked

Description

Return true if exactly one bit is set in the scan mask, false otherwise. It can be used for devices where only one channel can be active for sampling at a time.

int **iio_push_to_buffers**(struct iio_dev * indio_dev, const void * data)
push to a registered buffer.

Parameters

struct iio_dev * indio_dev iio_dev structure for device.

const void * data Full scan.

struct iio_buffer * **iio_buffer_get**(struct iio_buffer * buffer)
Grab a reference to the buffer

Parameters

struct iio_buffer * buffer The buffer to grab a reference for, may be NULL

Description

Returns the pointer to the buffer that was passed into the function.

void **iio_buffer_put**(struct iio_buffer * buffer)
Release the reference to the buffer

Parameters

struct iio_buffer * buffer The buffer to release the reference for, may be NULL

void **iio_device_attach_buffer**(struct iio_dev * indio_dev, struct iio_buffer * buffer)
Attach a buffer to a IIO device

Parameters

struct iio_dev * indio_dev The device the buffer should be attached to

struct iio_buffer * buffer The buffer to attach to the device

Description

This function attaches a buffer to a IIO device. The buffer stays attached to the device until the device is freed. The function should only be called at most once per device.

18.4 Triggers

- struct `iio_trigger` —industrial I/O trigger device
- `devm_iio_trigger_alloc()` —Resource-managed iio_trigger_alloc
- `devm_iio_trigger_register()` —Resource-managed iio_trigger_register iio_trigger_unregister
- `iio_trigger_validate_own_device()` —Check if a trigger and IIO device belong to the same device

In many situations it is useful for a driver to be able to capture data based on some external event (trigger) as opposed to periodically polling for data. An IIO trigger can be provided by a device driver that also has an IIO device based on hardware generated events (e.g. data ready or threshold exceeded) or provided by a separate driver from an independent interrupt source (e.g. GPIO line connected to some external system, timer interrupt or user space writing a specific file in sysfs). A trigger may initiate data capture for a number of sensors and also it may be completely unrelated to the sensor itself.

18.4.1 IIO trigger sysfs interface

There are two locations in sysfs related to triggers:

- `/sys/bus/iio/devices/triggerY/*`, this file is created once an IIO trigger is registered with the IIO core and corresponds to trigger with index Y. Because triggers can be very different depending on type there are few standard attributes that we can describe here:
  - `name`, trigger name that can be later used for association with a device.
  - `sampling_frequency`, some timer based triggers use this attribute to specify the frequency for trigger calls.
- `/sys/bus/iio/devices/iio:deviceX/trigger/*`, this directory is created once the device supports a triggered buffer. We can associate a trigger with our device by writing the trigger's name in the `current_trigger` file.

18.4.2 IIO trigger setup

Let's see a simple example of how to setup a trigger to be used by a driver:

```
struct iio_trigger_ops trigger_ops = {
    .set_trigger_state = sample_trigger_state,
    .validate_device = sample_validate_device,
}

struct iio_trigger *trig;

/* first, allocate memory for our trigger */
trig = iio_trigger_alloc(dev, "trig-%s-%d", name, idx);

/* setup trigger operations field */
trig->ops = &trigger_ops;

/* now register the trigger with the IIO core */
iio_trigger_register(trig);
```

18.4.3 IIO trigger ops

- struct `iio_trigger_ops` —operations structure for an iio_trigger.

Notice that a trigger has a set of operations attached:

- `set_trigger_state`, switch the trigger on/off on demand.
- `validate_device`, function to validate the device when the current trigger gets changed.

18.4.4 More details

struct **iio_trigger_ops**
operations structure for an iio_trigger.

Definition

```
struct iio_trigger_ops {
  int (*set_trigger_state)(struct iio_trigger *trig, bool state);
  int (*try_reenable)(struct iio_trigger *trig);
  int (*validate_device)(struct iio_trigger *trig, struct iio_dev *indio_
↪dev);
};
```

Members

set_trigger_state switch on/off the trigger on demand

try_reenable function to reenable the trigger when the use count is zero (may be NULL)

validate_device function to validate the device when the current trigger gets changed.

Description

This is typically static const within a driver and shared by instances of a given device.

struct **iio_trigger**
industrial I/O trigger device

Definition

```
struct iio_trigger {
  const struct iio_trigger_ops    *ops;
  struct module                   *owner;
  int id;
  const char                      *name;
  struct device                   dev;
  struct list_head                list;
  struct list_head                alloc_list;
  atomic_t use_count;
  struct irq_chip                 subirq_chip;
  int subirq_base;
  struct iio_subirq subirqs[CONFIG_IIO_CONSUMERS_PER_TRIGGER];
  unsigned long pool[BITS_TO_LONGS(CONFIG_IIO_CONSUMERS_PER_TRIGGER)];
  struct mutex                    pool_lock;
  bool attached_own_device;
};
```

Members

ops [DRIVER] operations structure

owner [INTERN] owner of this driver module

id [INTERN] unique id number

name [DRIVER] unique name

dev [DRIVER] associated device (if relevant)

list [INTERN] used in maintenance of global trigger list

alloc_list [DRIVER] used for driver specific trigger list

use_count [INTERN] use count for the trigger.

subirq_chip [INTERN] associate ‘virtual’ irq chip.

subirq_base [INTERN] base number for irqs provided by trigger.

subirqs [INTERN] information about the ‘child’ irqs.

pool [INTERN] bitmap of irqs currently in use.

pool_lock [INTERN] protection of the irq pool.

attached_own_device [INTERN] if we are using our own device as trigger, i.e. if we registered a poll function to the same device as the one providing the trigger.

void **iio_trigger_set_drvdata**(struct iio_trigger * trig, void * data)
Set trigger driver data

Parameters

struct iio_trigger * trig IIO trigger structure

void * data Driver specific data

Description

Allows to attach an arbitrary pointer to an IIO trigger, which can later be retrieved by `iio_trigger_get_drvdata()`.

void * **iio_trigger_get_drvdata**(struct iio_trigger * trig)
Get trigger driver data

Parameters

struct iio_trigger * trig IIO trigger structure

Description

Returns the data previously set with `iio_trigger_set_drvdata()`

iio_trigger_register(trig_info)
register a trigger with the IIO core

Parameters

trig_info trigger to be registered

void **iio_trigger_unregister**(struct iio_trigger * trig_info)
unregister a trigger from the core

Parameters

struct iio_trigger * trig_info trigger to be unregistered

int **iio_trigger_set_immutable**(struct iio_dev * indio_dev, struct iio_trigger * trig)
set an immutable trigger on destination

Parameters

struct iio_dev * indio_dev IIO device structure containing the device

struct iio_trigger * trig trigger to assign to device

void **iio_trigger_poll**(struct iio_trigger * trig)
called on a trigger occurring

Parameters

struct iio_trigger * trig trigger which occurred

Description

Typically called in relevant hardware interrupt handler.

bool **iio_trigger_using_own**(struct iio_dev * indio_dev)
tells us if we use our own HW trigger ourselves

Parameters

struct iio_dev * indio_dev device to check

struct iio_trigger * **devm_iio_trigger_alloc**(struct device * dev, const char * fmt, ...)
Resource-managed iio_trigger_alloc()

Parameters

struct device * dev Device to allocate iio_trigger for

const char * fmt trigger name format. If it includes format specifiers, the additional arguments following format are formatted and inserted in the resulting string replacing their respective specifiers.

... variable arguments

Description

Managed iio_trigger_alloc. iio_trigger allocated with this function is automatically freed on driver detach.

Return

Pointer to allocated iio_trigger on success, NULL on failure.

int **__devm_iio_trigger_register**(struct device * dev, struct iio_trigger * trig_info, struct module * this_mod)
Resource-managed `iio_trigger_register()`

Parameters

struct device * dev device this trigger was allocated for

struct iio_trigger * trig_info trigger to register

struct module * this_mod module registering the trigger

Description

Managed `iio_trigger_register()`. The IIO trigger registered with this function is automatically unregistered on driver detach. This function calls `iio_trigger_register()` internally. Refer to that function for more information.

Return

0 on success, negative error number on failure.

int **iio_trigger_validate_own_device**(struct iio_trigger * trig, struct iio_dev * indio_dev)

Check if a trigger and IIO device belong to the same device

Parameters

struct iio_trigger * trig The IIO trigger to check

struct iio_dev * indio_dev the IIO device to check

Description

This function can be used as the validate_device callback for triggers that can only be attached to their own device.

Return

0 if both the trigger and the IIO device belong to the same device, -EINVAL otherwise.

18.5 Triggered Buffers

Now that we know what buffers and triggers are let's see how they work together.

18.5.1 IIO triggered buffer setup

- `iio_triggered_buffer_setup()` —Setup triggered buffer and pollfunc
- `iio_triggered_buffer_cleanup()` —Free resources allocated by `iio_triggered_buffer_setup()`
- struct `iio_buffer_setup_ops` —buffer setup related callbacks

A typical triggered buffer setup looks like this:

```
const struct iio_buffer_setup_ops sensor_buffer_setup_ops = {
  .preenable    = sensor_buffer_preenable,
  .postenable   = sensor_buffer_postenable,
  .postdisable  = sensor_buffer_postdisable,
  .predisable   = sensor_buffer_predisable,
};

irqreturn_t sensor_iio_pollfunc(int irq, void *p)
{
    pf->timestamp = iio_get_time_ns((struct indio_dev *)p);
    return IRQ_WAKE_THREAD;
}

irqreturn_t sensor_trigger_handler(int irq, void *p)
{
    u16 buf[8];
    int i = 0;
```

(continues on next page)

(continued from previous page)

```
    /* read data for each active channel */
    for_each_set_bit(bit, active_scan_mask, masklength)
        buf[i++] = sensor_get_data(bit)

    iio_push_to_buffers_with_timestamp(indio_dev, buf, timestamp);

    iio_trigger_notify_done(trigger);
    return IRQ_HANDLED;
}

/* setup triggered buffer, usually in probe function */
iio_triggered_buffer_setup(indio_dev, sensor_iio_polfunc,
                           sensor_trigger_handler,
                           sensor_buffer_setup_ops);
```

The important things to notice here are:

- `iio_buffer_setup_ops`, the buffer setup functions to be called at predefined points in the buffer configuration sequence (e.g. before enable, after disable). If not specified, the IIO core uses the default iio_triggered_buffer_setup_ops.
- **sensor_iio_pollfunc**, the function that will be used as top half of poll function. It should do as little processing as possible, because it runs in interrupt context. The most common operation is recording of the current timestamp and for this reason one can use the IIO core defined `iio_pollfunc_store_time()` function.
- **sensor_trigger_handler**, the function that will be used as bottom half of the poll function. This runs in the context of a kernel thread and all the processing takes place here. It usually reads data from the device and stores it in the internal buffer together with the timestamp recorded in the top half.

18.5.2 More details

int **iio_triggered_buffer_setup**(struct iio_dev * indio_dev, irqreturn_t (*h)(int irq, void *p), irqreturn_t (*thread) (int irq, void *p), const struct iio_buffer_setup_ops * setup_ops)

Setup triggered buffer and pollfunc

Parameters

struct iio_dev * indio_dev IIO device structure

irqreturn_t (*)(int irq, void *p) h Function which will be used as pollfunc top half

irqreturn_t (*)(int irq, void *p) thread Function which will be used as pollfunc bottom half

const struct iio_buffer_setup_ops * setup_ops Buffer setup functions to use for this device. If NULL the default setup functions for triggered buffers will be used.

Description

This function combines some common tasks which will normally be performed when setting up a triggered buffer. It will allocate the buffer and the pollfunc.

Before calling this function the indio_dev structure should already be completely initialized, but not yet registered. In practice this means that this function should be called right before `iio_device_register()`.

To free the resources allocated by this function call `iio_triggered_buffer_cleanup()`.

void **iio_triggered_buffer_cleanup**(struct iio_dev * indio_dev)
Free resources allocated by `iio_triggered_buffer_setup()`

Parameters

struct iio_dev * indio_dev IIO device structure

18.6 HW consumer

An IIO device can be directly connected to another device in hardware. In this case the buffers between IIO provider and IIO consumer are handled by hardware. The Industrial I/O HW consumer offers a way to bond these IIO devices without software buffer for data. The implementation can be found under `drivers/iio/buffer/hw-consumer.c`

- struct `iio_hw_consumer` —Hardware consumer structure
- `iio_hw_consumer_alloc()` —Allocate IIO hardware consumer
- `iio_hw_consumer_free()` —Free IIO hardware consumer
- `iio_hw_consumer_enable()` —Enable IIO hardware consumer
- `iio_hw_consumer_disable()` —Disable IIO hardware consumer

18.6.1 HW consumer setup

As standard IIO device the implementation is based on IIO provider/consumer. A typical IIO HW consumer setup looks like this:

```
static struct iio_hw_consumer *hwc;

static const struct iio_info adc_info = {
        .read_raw = adc_read_raw,
};

static int adc_read_raw(struct iio_dev *indio_dev,
                        struct iio_chan_spec const *chan, int *val,
                        int *val2, long mask)
{
        ret = iio_hw_consumer_enable(hwc);

        /* Acquire data */

        ret = iio_hw_consumer_disable(hwc);
```

(continues on next page)

(continued from previous page)

```
}

static int adc_probe(struct platform_device *pdev)
{
        hwc = devm_iio_hw_consumer_alloc(&iio->dev);
}
```

18.6.2 More details

struct iio_hw_consumer * **iio_hw_consumer_alloc**(struct device * dev)
Allocate IIO hardware consumer

Parameters

struct device * dev Pointer to consumer device.

Description

Returns a valid iio_hw_consumer on success or a ERR_PTR() on failure.

void **iio_hw_consumer_free**(struct iio_hw_consumer * hwc)
Free IIO hardware consumer

Parameters

struct iio_hw_consumer * hwc hw consumer to free.

struct iio_hw_consumer * **devm_iio_hw_consumer_alloc**(struct device * dev)
Resource-managed `iio_hw_consumer_alloc()`

Parameters

struct device * dev Pointer to consumer device.

Description

Managed iio_hw_consumer_alloc. iio_hw_consumer allocated with this function is automatically freed on driver detach.

returns pointer to allocated iio_hw_consumer on success, NULL on failure.

int **iio_hw_consumer_enable**(struct iio_hw_consumer * hwc)
Enable IIO hardware consumer

Parameters

struct iio_hw_consumer * hwc iio_hw_consumer to enable.

Description

Returns 0 on success.

void **iio_hw_consumer_disable**(struct iio_hw_consumer * hwc)
Disable IIO hardware consumer

Parameters

struct iio_hw_consumer * hwc iio_hw_consumer to disable.

  ktime_t timestamp[INPUT_CLK_MAX];
};
```

Members

name name of the device

phys physical path to the device in the system hierarchy

uniq unique identification code for the device (if device has it)

id id of the device (struct input_id)

propbit bitmap of device properties and quirks

evbit bitmap of types of events supported by the device (EV_KEY, EV_REL, etc.)

keybit bitmap of keys/buttons this device has

relbit bitmap of relative axes for the device

absbit bitmap of absolute axes for the device

mscbit bitmap of miscellaneous events supported by the device

ledbit bitmap of leds present on the device

sndbit bitmap of sound effects supported by the device

ffbit bitmap of force feedback effects supported by the device

swbit bitmap of switches present on the device

hint_events_per_packet average number of events generated by the device in a packet (between EV_SYN/SYN_REPORT events). Used by event handlers to estimate size of the buffer needed to hold events.

keycodemax size of keycode table

keycodesize size of elements in keycode table

keycode map of scancodes to keycodes for this device

setkeycode optional method to alter current keymap, used to implement sparse keymaps. If not supplied default mechanism will be used. The method is being called while holding event_lock and thus must not sleep

getkeycode optional legacy method to retrieve current keymap.

ff force feedback structure associated with the device if device supports force feedback effects

poller poller structure associated with the device if device is set up to use polling mode

repeat_key stores key code of the last key pressed; used to implement software autorepeat

timer timer for software autorepeat

rep current values for autorepeat parameters (delay, rate)

mt pointer to multitouch state

absinfo array of `struct input_absinfo` elements holding information about absolute axes (current value, min, max, flat, fuzz, resolution)

key reflects current state of device's keys/buttons

led reflects current state of device's LEDs

snd reflects current state of sound effects

sw reflects current state of device's switches

open this method is called when the very first user calls `input_open_device()`. The driver must prepare the device to start generating events (start polling thread, request an IRQ, submit URB, etc.)

close this method is called when the very last user calls `input_close_device()`.

flush purges the device. Most commonly used to get rid of force feedback effects loaded into the device when disconnecting from it

event event handler for events sent _to_ the device, like EV_LED or EV_SND. The device is expected to carry out the requested action (turn on a LED, play sound, etc.) The call is protected by **event_lock** and must not sleep

grab input handle that currently has the device grabbed (via EVIOCGRAB ioctl). When a handle grabs a device it becomes sole recipient for all input events coming from the device

event_lock this spinlock is taken when input core receives and processes a new event for the device (in `input_event()`). Code that accesses and/or modifies parameters of a device (such as keymap or absmin, absmax, absfuzz, etc.) after device has been registered with input core must take this lock.

mutex serializes calls to open(), close() and flush() methods

users stores number of users (input handlers) that opened this device. It is used by `input_open_device()` and `input_close_device()` to make sure that dev->open() is only called when the first user opens device and dev->close() is called when the very last user closes the device

going_away marks devices that are in a middle of unregistering and causes input_open_device*() fail with -ENODEV.

dev driver model' s view of this device

h_list list of input handles associated with the device. When accessing the list dev->mutex must be held

node used to place the device onto input_dev_list

num_vals number of values queued in the current frame

max_vals maximum number of values queued in a frame

vals array of values queued in the current frame

devres_managed indicates that devices is managed with devres framework and needs not be explicitly unregistered or freed.

timestamp storage for a timestamp set by input_set_timestamp called by a driver

struct **input_handler**
implements one of interfaces for input devices

Definition

```
struct input_handler {
  void *private;
  void (*event)(struct input_handle *handle, unsigned int type, unsigned␣
↪int code, int value);
  void (*events)(struct input_handle *handle, const struct input_value␣
↪*vals, unsigned int count);
  bool (*filter)(struct input_handle *handle, unsigned int type, unsigned␣
↪int code, int value);
  bool (*match)(struct input_handler *handler, struct input_dev *dev);
  int (*connect)(struct input_handler *handler, struct input_dev *dev,␣
↪const struct input_device_id *id);
  void (*disconnect)(struct input_handle *handle);
  void (*start)(struct input_handle *handle);
  bool legacy_minors;
  int minor;
  const char *name;
  const struct input_device_id *id_table;
  struct list_head        h_list;
  struct list_head        node;
};
```

Members

private driver-specific data

event event handler. This method is being called by input core with interrupts disabled and dev->event_lock spinlock held and so it may not sleep

events event sequence handler. This method is being called by input core with interrupts disabled and dev->event_lock spinlock held and so it may not sleep

filter similar to **event**; separates normal event handlers from "filters".

match called after comparing device's id with handler's id_table to perform fine-grained matching between device and handler

connect called when attaching a handler to an input device

disconnect disconnects a handler from input device

start starts handler for given handle. This function is called by input core right after connect() method and also when a process that "grabbed" a device releases it

legacy_minors set to `true` by drivers using legacy minor ranges

minor beginning of range of 32 legacy minors for devices this driver can provide

name name of the handler, to be shown in /proc/bus/input/handlers

id_table pointer to a table of input_device_ids this driver can handle

h_list list of input handles associated with the handler

node for placing the driver onto input_handler_list

Description

Input handlers attach to input devices and create input handles. There are likely several handlers attached to any given input device at the same time. All of them will get their copy of input event generated by the device.

The very same structure is used to implement input filters. Input core allows filters to run first and will not pass event to regular handlers if any of the filters indicate that the event should be filtered (by returning `true` from their filter() method).

Note that input core serializes calls to connect() and disconnect() methods.

struct **input_handle**
links input device with an input handler

Definition

```
struct input_handle {
  void *private;
  int open;
  const char *name;
  struct input_dev *dev;
  struct input_handler *handler;
  struct list_head        d_node;
  struct list_head        h_node;
};
```

Members

private handler-specific data

open counter showing whether the handle is ‘open’, i.e. should deliver events from its device

name name given to the handle by handler that created it

dev input device the handle is attached to

handler handler that works with the device through this handle

d_node used to put the handle on device’s list of attached handles

h_node used to put the handle on handler’s list of handles from which it gets events

void **input_set_events_per_packet**(struct input_dev * dev, int n_events)
tell handlers about the driver event rate

Parameters

struct input_dev * dev the input device used by the driver

int n_events the average number of events between calls to input_sync()

Description

If the event rate sent from a device is unusually large, use this function to set the expected event rate. This will allow handlers to set up an appropriate buffer size for the event stream, in order to minimize information loss.

struct **ff_device**
force-feedback part of an input device

Definition

```
struct ff_device {
  int (*upload)(struct input_dev *dev, struct ff_effect *effect, struct ff_
↪effect *old);
  int (*erase)(struct input_dev *dev, int effect_id);
  int (*playback)(struct input_dev *dev, int effect_id, int value);
  void (*set_gain)(struct input_dev *dev, u16 gain);
  void (*set_autocenter)(struct input_dev *dev, u16 magnitude);
  void (*destroy)(struct ff_device *);
  void *private;
  unsigned long ffbit[BITS_TO_LONGS(FF_CNT)];
  struct mutex mutex;
  int max_effects;
  struct ff_effect *effects;
  struct file *effect_owners[];
};
```

Members

upload Called to upload an new effect into device

erase Called to erase an effect from device

playback Called to request device to start playing specified effect

set_gain Called to set specified gain

set_autocenter Called to auto-center device

destroy called by input core when parent input device is being destroyed

private driver-specific data, will be freed automatically

ffbit bitmap of force feedback capabilities truly supported by device (not emulated like ones in input_dev->ffbit)

mutex mutex for serializing access to the device

max_effects maximum number of effects supported by device

effects pointer to an array of effects currently loaded into device

effect_owners array of effect owners; when file handle owning an effect gets closed the effect is automatically erased

Description

Every force-feedback device must implement upload() and playback() methods; erase() is optional. set_gain() and set_autocenter() need only be implemented if driver sets up FF_GAIN and FF_AUTOCENTER bits.

Note that playback(), set_gain() and set_autocenter() are called with dev->event_lock spinlock held and interrupts off and thus may not sleep.

void **input_event**(struct input_dev * dev, unsigned int type, unsigned int code, int value)
report new input event

Parameters

struct input_dev * dev device that generated the event

unsigned int type type of the event

unsigned int code event code

int value value of the event

Description

This function should be used by drivers implementing various input devices to report input events. See also `input_inject_event()`.

NOTE

`input_event()` may be safely used right after input device was allocated with `input_allocate_device()`, even before it is registered with `input_register_device()`, but the event will not reach any of the input handlers. Such early invocation of `input_event()` may be used to 'seed' initial state of a switch or initial position of absolute axis, etc.

void **input_inject_event**(struct input_handle * handle, unsigned int type, unsigned int code, int value)
send input event from input handler

Parameters

struct input_handle * handle input handle to send event through

unsigned int type type of the event

unsigned int code event code

int value value of the event

Description

Similar to `input_event()` but will ignore event if device is “grabbed” and handle injecting event is not the one that owns the device.

void **input_alloc_absinfo**(struct input_dev * dev)
allocates array of input_absinfo structs

Parameters

struct input_dev * dev the input device emitting absolute events

Description

If the absinfo struct the caller asked for is already allocated, this functions will not do anything.

int **input_grab_device**(struct input_handle * handle)
grabs device for exclusive use

Parameters

struct input_handle * handle input handle that wants to own the device

Description

When a device is grabbed by an input handle all events generated by the device are delivered only to this handle. Also events injected by other input handles are ignored while device is grabbed.

void **input_release_device**(struct input_handle * handle)
release previously grabbed device

Parameters

struct input_handle * handle input handle that owns the device

Description

Releases previously grabbed device so that other input handles can start receiving input events. Upon release all handlers attached to the device have their start() method called so they have a change to synchronize device state with the rest of the system.

int **input_open_device**(struct input_handle * handle)
open input device

Parameters

struct input_handle * handle handle through which device is being accessed

Description

This function should be called by input handlers when they want to start receive events from given input device.

void **input_close_device**(struct input_handle * handle)
close input device

Parameters

struct input_handle * handle handle through which device is being accessed

Description

This function should be called by input handlers when they want to stop receive events from given input device.

int **input_scancode_to_scalar**(const struct input_keymap_entry * ke, unsigned int * scancode)
converts scancode in `struct input_keymap_entry`

Parameters

const struct input_keymap_entry * ke keymap entry containing scancode to be converted.

unsigned int * scancode pointer to the location where converted scancode should be stored.

Description

This function is used to convert scancode stored in `struct keymap_entry` into scalar form understood by legacy keymap handling methods. These methods expect scancodes to be represented as 'unsigned int'.

int **input_get_keycode**(struct input_dev * dev, struct input_keymap_entry * ke)
retrieve keycode currently mapped to a given scancode

Parameters

struct input_dev * dev input device which keymap is being queried

struct input_keymap_entry * ke keymap entry

Description

This function should be called by anyone interested in retrieving current keymap. Presently evdev handlers use it.

int **input_set_keycode**(struct input_dev * dev, const struct input_keymap_entry * ke)
attribute a keycode to a given scancode

Parameters

struct input_dev * dev input device which keymap is being updated

const struct input_keymap_entry * ke new keymap entry

Description

This function should be called by anyone needing to update current keymap. Presently keyboard and evdev handlers use it.

void **input_reset_device**(struct input_dev * dev)
reset/restore the state of input device

Parameters

struct input_dev * dev input device whose state needs to be reset

Description

This function tries to reset the state of an opened input device and bring internal state and state if the hardware in sync with each other. We mark all keys as released, restore LED state, repeat rate, etc.

struct input_dev * **input_allocate_device**(void)
allocate memory for new input device

Parameters

void no arguments

Description

Returns prepared struct input_dev or `NULL`.

NOTE

Use `input_free_device()` to free devices that have not been registered; `input_unregister_device()` should be used for already registered devices.

struct input_dev * **devm_input_allocate_device**(struct device * dev)
allocate managed input device

Parameters

struct device * dev device owning the input device being created

Description

Returns prepared struct input_dev or `NULL`.

Managed input devices do not need to be explicitly unregistered or freed as it will be done automatically when owner device unbinds from its driver (or binding fails). Once managed input device is allocated, it is ready to be set up and registered in the same fashion as regular input device. There are no special devm_input_device_[un]register() variants, regular ones work with both managed and unmanaged devices, should you need them. In most cases however, managed input device need not be explicitly unregistered or freed.

NOTE

the owner device is set up as parent of input device and users should not override it.

void **input_free_device**(struct input_dev * dev)
free memory occupied by input_dev structure

Parameters

struct input_dev * dev input device to free

Description

This function should only be used if `input_register_device()` was not called yet or if it failed. Once device was registered use `input_unregister_device()` and memory will be freed once last reference to the device is dropped.

Device should be allocated by `input_allocate_device()`.

NOTE

If there are references to the input device then memory will not be freed until last reference is dropped.

void **input_set_timestamp**(struct input_dev * dev, ktime_t timestamp)
set timestamp for input events

Parameters

struct input_dev * dev input device to set timestamp for

ktime_t timestamp the time at which the event has occurred in CLOCK_MONOTONIC

Description

This function is intended to provide to the input system a more accurate time of when an event actually occurred. The driver should call this function as soon as a timestamp is acquired ensuring clock conversions in input_set_timestamp are done correctly.

The system entering suspend state between timestamp acquisition and calling input_set_timestamp can result in inaccurate conversions.

ktime_t * **input_get_timestamp**(struct input_dev * dev)
get timestamp for input events

Parameters

struct input_dev * dev input device to get timestamp from

Description

A valid timestamp is a timestamp of non-zero value.

void **input_set_capability**(struct input_dev * dev, unsigned int type, unsigned int code)
mark device as capable of a certain event

Parameters

struct input_dev * dev device that is capable of emitting or accepting event

unsigned int type type of the event (EV_KEY, EV_REL, etc…)

unsigned int code event code

Description

In addition to setting up corresponding bit in appropriate capability bitmap the function also adjusts dev->evbit.

void **input_enable_softrepeat**(struct input_dev * dev, int delay, int period)
enable software autorepeat

Parameters

struct input_dev * dev input device

int delay repeat delay

int period repeat period

Description

Enable software autorepeat on the input device.

int **input_register_device**(struct input_dev * dev)
register device with input core

Parameters

struct input_dev * dev device to be registered

Description

This function registers device with input core. The device must be allocated with `input_allocate_device()` and all it' s capabilities set up before registering. If function fails the device must be freed with `input_free_device()`. Once device has been successfully registered it can be unregistered with `input_unregister_device()`; `input_free_device()` should not be called in this case.

Note that this function is also used to register managed input devices (ones allocated with `devm_input_allocate_device()`). Such managed input devices need not be explicitly unregistered or freed, their tear down is controlled by the devres infrastructure. It is also worth noting that tear down of managed input devices is internally a 2-step process: registered managed input device is first unregistered, but stays in memory and can still handle `input_event()` calls (although events will not be delivered anywhere). The freeing of managed input device will happen later, when devres stack is unwound to the point where device allocation was made.

void **input_unregister_device**(struct input_dev * dev)
unregister previously registered device

Parameters

struct input_dev * dev device to be unregistered

Description

This function unregisters an input device. Once device is unregistered the caller should not try to access it as it may get freed at any moment.

int **input_register_handler**(struct input_handler * handler)
register a new input handler

Parameters

struct input_handler * handler handler to be registered

Description

This function registers a new input handler (interface) for input devices in the system and attaches it to all input devices that are compatible with the handler.

void **input_unregister_handler**(struct input_handler * handler)
unregisters an input handler

Parameters

struct input_handler * handler handler to be unregistered

Description

This function disconnects a handler from its input devices and removes it from lists of known handlers.

int **input_handler_for_each_handle**(struct input_handler * handler, void * data, int (*fn)(struct input_handle *, void *))
handle iterator

Parameters

struct input_handler * handler input handler to iterate

void * data data for the callback

int (*)(struct input_handle *, void *) fn function to be called for each handle

Description

Iterate over **bus**'s list of devices, and call **fn** for each, passing it **data** and stop when **fn** returns a non-zero value. The function is using RCU to traverse the list and therefore may be using in atomic contexts. The **fn** callback is invoked from RCU critical section and thus must not sleep.

int **input_register_handle**(struct input_handle * handle)
register a new input handle

Parameters

struct input_handle * handle handle to register

Description

This function puts a new input handle onto device's and handler's lists so that events can flow through it once it is opened using `input_open_device()`.

This function is supposed to be called from handler's connect() method.

void **input_unregister_handle**(struct input_handle * handle)
unregister an input handle

Parameters

struct input_handle * handle handle to unregister

Description

This function removes input handle from device's and handler's lists.

This function is supposed to be called from handler's disconnect() method.

int **input_get_new_minor**(int legacy_base, unsigned int legacy_num, bool allow_dynamic)
allocates a new input minor number

Parameters

int legacy_base beginning or the legacy range to be searched

unsigned int legacy_num size of legacy range

bool allow_dynamic whether we can also take ID from the dynamic range

Description

This function allocates a new device minor for from input major namespace. Caller can request legacy minor by specifying **legacy_base** and **legacy_num** parameters

and whether ID can be allocated from dynamic range if there are no free IDs in legacy range.

void **input_free_minor**(unsigned int minor)
release previously allocated minor

Parameters

unsigned int minor minor to be released

Description

This function releases previously allocated input minor so that it can be reused later.

int **input_ff_upload**(struct input_dev * dev, struct ff_effect * effect, struct file * file)
upload effect into force-feedback device

Parameters

struct input_dev * dev input device

struct ff_effect * effect effect to be uploaded

struct file * file owner of the effect

int **input_ff_erase**(struct input_dev * dev, int effect_id, struct file * file)
erase a force-feedback effect from device

Parameters

struct input_dev * dev input device to erase effect from

int effect_id id of the effect to be erased

struct file * file purported owner of the request

Description

This function erases a force-feedback effect from specified device. The effect will only be erased if it was uploaded through the same file handle that is requesting erase.

int **input_ff_event**(struct input_dev * dev, unsigned int type, unsigned int code, int value)
generic handler for force-feedback events

Parameters

struct input_dev * dev input device to send the effect to

unsigned int type event type (anything but EV_FF is ignored)

unsigned int code event code

int value event value

int **input_ff_create**(struct input_dev * dev, unsigned int max_effects)
create force-feedback device

Parameters

struct input_dev * dev input device supporting force-feedback

unsigned int max_effects maximum number of effects supported by the device

Description

This function allocates all necessary memory for a force feedback portion of an input device and installs all default handlers. **dev->ffbit** should be already set up before calling this function. Once ff device is created you need to setup its upload, erase, playback and other handlers before registering input device

void **input_ff_destroy**(struct input_dev * dev)
frees force feedback portion of input device

Parameters

struct input_dev * dev input device supporting force feedback

Description

This function is only needed in error path as input core will automatically free force feedback structures when device is destroyed.

int **input_ff_create_memless**(struct input_dev * dev, void * data, int (*play_effect)(struct input_dev *, void *, struct ff_effect *))
create memoryless force-feedback device

Parameters

struct input_dev * dev input device supporting force-feedback

void * data driver-specific data to be passed into **play_effect**

int (*)(struct input_dev *, void *, struct ff_effect *) play_effect
driver-specific method for playing FF effect

19.2 Multitouch Library

struct **input_mt_slot**
represents the state of an input MT slot

Definition

```
struct input_mt_slot {
  int abs[ABS_MT_LAST - ABS_MT_FIRST + 1];
  unsigned int frame;
  unsigned int key;
};
```

Members

abs holds current values of ABS_MT axes for this slot

frame last frame at which `input_mt_report_slot_state()` was called

key optional driver designation of this slot

struct **input_mt**
state of tracked contacts

Definition

```
struct input_mt {
  int trkid;
  int num_slots;
  int slot;
  unsigned int flags;
  unsigned int frame;
  int *red;
  struct input_mt_slot slots[];
};
```

Members

trkid stores MT tracking ID for the next contact

num_slots number of MT slots the device uses

slot MT slot currently being transmitted

flags input_mt operation flags

frame increases every time `input_mt_sync_frame()` is called

red reduced cost matrix for in-kernel tracking

slots array of slots holding current values of tracked contacts

struct **input_mt_pos**
    contact position

Definition

```
struct input_mt_pos {
  s16 x, y;
};
```

Members

x horizontal coordinate

y vertical coordinate

int **input_mt_init_slots**(struct input_dev * dev, unsigned int num_slots,
unsigned int flags)
    initialize MT input slots

Parameters

struct input_dev * dev input device supporting MT events and finger tracking

unsigned int num_slots number of slots used by the device

unsigned int flags mt tasks to handle in core

Description

This function allocates all necessary memory for MT slot handling in the input device, prepares the ABS_MT_SLOT and ABS_MT_TRACKING_ID events for use and sets up appropriate buffers. Depending on the flags set, it also performs pointer emulation and frame synchronization.

May be called repeatedly. Returns -EINVAL if attempting to reinitialize with a different number of slots.

void **input_mt_destroy_slots**(struct input_dev * dev)
frees the MT slots of the input device

Parameters

struct input_dev * dev input device with allocated MT slots

Description

This function is only needed in error path as the input core will automatically free the MT slots when the device is destroyed.

bool **input_mt_report_slot_state**(struct input_dev * dev, unsigned int tool_type, bool active)
report contact state

Parameters

struct input_dev * dev input device with allocated MT slots

unsigned int tool_type the tool type to use in this slot

bool active true if contact is active, false otherwise

Description

Reports a contact via ABS_MT_TRACKING_ID, and optionally ABS_MT_TOOL_TYPE. If active is true and the slot is currently inactive, or if the tool type is changed, a new tracking id is assigned to the slot. The tool type is only reported if the corresponding absbit field is set.

Returns true if contact is active.

void **input_mt_report_finger_count**(struct input_dev * dev, int count)
report contact count

Parameters

struct input_dev * dev input device with allocated MT slots

int count the number of contacts

Description

Reports the contact count via BTN_TOOL_FINGER, BTN_TOOL_DOUBLETAP, BTN_TOOL_TRIPLETAP and BTN_TOOL_QUADTAP.

The input core ensures only the KEY events already setup for this device will produce output.

void **input_mt_report_pointer_emulation**(struct input_dev * dev, bool use_count)
common pointer emulation

Parameters

struct input_dev * dev input device with allocated MT slots

bool use_count report number of active contacts as finger count

Description

Performs legacy pointer emulation via BTN_TOUCH, ABS_X, ABS_Y and ABS_PRESSURE. Touchpad finger count is emulated if use_count is true.

The input core ensures only the KEY and ABS axes already setup for this device will produce output.

void **input_mt_drop_unused**(struct input_dev * dev)
Inactivate slots not seen in this frame

Parameters

struct input_dev * dev input device with allocated MT slots

Description

Lift all slots not seen since the last call to this function.

void **input_mt_sync_frame**(struct input_dev * dev)
synchronize mt frame

Parameters

struct input_dev * dev input device with allocated MT slots

Description

Close the frame and prepare the internal state for a new one. Depending on the flags, marks unused slots as inactive and performs pointer emulation.

int **input_mt_assign_slots**(struct input_dev * dev, int * slots, const struct input_mt_pos * pos, int num_pos, int dmax)
perform a best-match assignment

Parameters

struct input_dev * dev input device with allocated MT slots

int * slots the slot assignment to be filled

const struct input_mt_pos * pos the position array to match

int num_pos number of positions

int dmax maximum ABS_MT_POSITION displacement (zero for infinite)

Description

Performs a best match against the current contacts and returns the slot assignment list. New contacts are assigned to unused slots.

The assignments are balanced so that all coordinate displacements are below the euclidian distance dmax. If no such assignment can be found, some contacts are assigned to unused slots.

Returns zero on success, or negative error in case of failure.

int **input_mt_get_slot_by_key**(struct input_dev * dev, int key)
return slot matching key

Parameters

struct input_dev * dev input device with allocated MT slots

int key the key of the sought slot

Description

Returns the slot of the given key, if it exists, otherwise set the key on the first unused slot and return.

If no available slot can be found, -1 is returned. Note that for this function to work properly, `input_mt_sync_frame()` has to be called at each frame.

19.3 Polled input devices

struct **input_polled_dev**
simple polled input device

Definition

```
struct input_polled_dev {
  void *private;
  void (*open)(struct input_polled_dev *dev);
  void (*close)(struct input_polled_dev *dev);
  void (*poll)(struct input_polled_dev *dev);
  unsigned int poll_interval;
  unsigned int poll_interval_max;
  unsigned int poll_interval_min;
  struct input_dev *input;
};
```

Members

private private driver data.

open driver-supplied method that prepares device for polling (enabled the device and maybe flushes device state).

close driver-supplied method that is called when device is no longer being polled. Used to put device into low power mode.

poll driver-supplied method that polls the device and posts input events (mandatory).

poll_interval specifies how often the poll() method should be called. Defaults to 500 msec unless overridden when registering the device.

poll_interval_max specifies upper bound for the poll interval. Defaults to the initial value of **poll_interval**.

poll_interval_min specifies lower bound for the poll interval. Defaults to 0.

input input device structure associated with the polled device. Must be properly initialized by the driver (id, name, phys, bits).

Description

Polled input device provides a skeleton for supporting simple input devices that do not raise interrupts but have to be periodically scanned or polled to detect changes in their state.

struct input_polled_dev * **input_allocate_polled_device**(void)
allocate memory for polled device

Parameters

void no arguments

Description

The function allocates memory for a polled device and also for an input device associated with this polled device.

struct input_polled_dev * **devm_input_allocate_polled_device**(struct device * dev)
allocate managed polled device

Parameters

struct device * dev device owning the polled device being created

Description

Returns prepared `struct input_polled_dev` or `NULL`.

Managed polled input devices do not need to be explicitly unregistered or freed as it will be done automatically when owner device unbinds from * its driver (or binding fails). Once such managed polled device is allocated, it is ready to be set up and registered in the same fashion as regular polled input devices (using `input_register_polled_device()` function).

If you want to manually unregister and free such managed polled devices, it can be still done by calling `input_unregister_polled_device()` and `input_free_polled_device()`, although it is rarely needed.

NOTE

the owner device is set up as parent of input device and users should not override it.

void **input_free_polled_device**(struct input_polled_dev * dev)
free memory allocated for polled device

Parameters

struct input_polled_dev * dev device to free

Description

The function frees memory allocated for polling device and drops reference to the associated input device.

int **input_register_polled_device**(struct input_polled_dev * dev)
register polled device

Parameters

struct input_polled_dev * dev device to register

Description

The function registers previously initialized polled input device with input layer. The device should be allocated with call to `input_allocate_polled_device()`. Callers should also set up poll() method and set up capabilities (id, name, phys, bits) of the corresponding input_dev structure.

void **input_unregister_polled_device**(struct input_polled_dev * dev)
unregister polled device

Parameters

struct input_polled_dev * dev device to unregister

Description

The function unregisters previously registered polled input device from input layer. Polling is stopped and device is ready to be freed with call to `input_free_polled_device()`.

19.4 Matrix keyboards/keypads

struct **matrix_keymap_data**
keymap for matrix keyboards

Definition

```
struct matrix_keymap_data {
  const uint32_t *keymap;
  unsigned int    keymap_size;
};
```

Members

keymap pointer to array of uint32 values encoded with KEY() macro representing keymap

keymap_size number of entries (initialized) in this keymap

Description

This structure is supposed to be used by platform code to supply keymaps to drivers that implement matrix-like keypads/keyboards.

struct **matrix_keypad_platform_data**
platform-dependent keypad data

Definition

```
struct matrix_keypad_platform_data {
  const struct matrix_keymap_data *keymap_data;
  const unsigned int *row_gpios;
  const unsigned int *col_gpios;
  unsigned int    num_row_gpios;
  unsigned int    num_col_gpios;
  unsigned int    col_scan_delay_us;
  unsigned int    debounce_ms;
  unsigned int    clustered_irq;
  unsigned int    clustered_irq_flags;
  bool active_low;
  bool wakeup;
  bool no_autorepeat;
  bool drive_inactive_cols;
};
```

Members

keymap_data pointer to `matrix_keymap_data`

row_gpios pointer to array of gpio numbers representing rows

col_gpios pointer to array of gpio numbers reporesenting colums

num_row_gpios actual number of row gpios used by device

num_col_gpios actual number of col gpios used by device

col_scan_delay_us delay, measured in microseconds, that is needed before we can keypad after activating column gpio

debounce_ms debounce interval in milliseconds

clustered_irq may be specified if interrupts of all row/column GPIOs are bundled to one single irq

clustered_irq_flags flags that are needed for the clustered irq

active_low gpio polarity

wakeup controls whether the device should be set up as wakeup source

no_autorepeat disable key autorepeat

drive_inactive_cols drive inactive columns during scan, rather than making them inputs.

Description

This structure represents platform-specific data that use used by matrix_keypad driver to perform proper initialization.

19.5 Sparse keymap support

struct **key_entry**
keymap entry for use in sparse keymap

Definition

```
struct key_entry {
  int type;
  u32 code;
  union {
    u16 keycode;
    struct {
      u8 code;
      u8 value;
    } sw;
  };
};
```

Members

type Type of the key entry (KE_KEY, KE_SW, KE_VSW, KE_END); drivers are allowed to extend the list with their own private definitions.

code Device-specific data identifying the button/switch

{unnamed_union} anonymous

keycode KEY_* code assigned to a key/button

sw.code SW_* code assigned to a switch

sw.value Value that should be sent in an input even when KE_SW switch is toggled. KE_VSW switches ignore this field and expect driver to supply value for the event.

Description

This structure defines an entry in a sparse keymap used by some input devices for which traditional table-based approach is not suitable.

struct key_entry * **sparse_keymap_entry_from_scancode**(struct input_dev * dev, unsigned int code)

perform sparse keymap lookup

Parameters

struct input_dev * dev Input device using sparse keymap

unsigned int code Scan code

Description

This function is used to perform `struct key_entry` lookup in an input device using sparse keymap.

struct key_entry * **sparse_keymap_entry_from_keycode**(struct input_dev * dev, unsigned int keycode)

perform sparse keymap lookup

Parameters

struct input_dev * dev Input device using sparse keymap

unsigned int keycode Key code

Description

This function is used to perform `struct key_entry` lookup in an input device using sparse keymap.

int **sparse_keymap_setup**(struct input_dev * dev, const struct key_entry * keymap, int (*setup)(struct input_dev *, struct key_entry *))

set up sparse keymap for an input device

Parameters

struct input_dev * dev Input device

const struct key_entry * keymap Keymap in form of array of `key_entry` structures ending with `KE_END` type entry

int (*)(struct input_dev *, struct key_entry *) setup Function that can be used to adjust keymap entries depending on device's needs, may be `NULL`

Description

The function calculates size and allocates copy of the original keymap after which sets up input device event bits appropriately. The allocated copy of the keymap is automatically freed when it is no longer needed.

void **sparse_keymap_report_entry**(struct input_dev * dev, const struct key_entry * ke, unsigned int value, bool autorelease)
report event corresponding to given key entry

Parameters

struct input_dev * dev Input device for which event should be reported

const struct key_entry * ke key entry describing event

unsigned int value Value that should be reported (ignored by KE_SW entries)

bool autorelease Signals whether release event should be emitted for KE_KEY entries right after reporting press event, ignored by all other entries

Description

This function is used to report input event described by given `struct key_entry`.

bool **sparse_keymap_report_event**(struct input_dev * dev, unsigned int code, unsigned int value, bool autorelease)
report event corresponding to given scancode

Parameters

struct input_dev * dev Input device using sparse keymap

unsigned int code Scan code

unsigned int value Value that should be reported (ignored by KE_SW entries)

bool autorelease Signals whether release event should be emitted for KE_KEY entries right after reporting press event, ignored by all other entries

Description

This function is used to perform lookup in an input device using sparse keymap and report corresponding event. Returns `true` if lookup was successful and `false` otherwise.

CHAPTER

TWENTY

LINUX USB API

20.1 The Linux-USB Host Side API

20.1.1 Introduction to USB on Linux

A Universal Serial Bus (USB) is used to connect a host, such as a PC or workstation, to a number of peripheral devices. USB uses a tree structure, with the host as the root (the system's master), hubs as interior nodes, and peripherals as leaves (and slaves). Modern PCs support several such trees of USB devices, usually a few USB 3.0 (5 GBit/s) or USB 3.1 (10 GBit/s) and some legacy USB 2.0 (480 MBit/s) busses just in case.

That master/slave asymmetry was designed-in for a number of reasons, one being ease of use. It is not physically possible to mistake upstream and downstream or it does not matter with a type C plug (or they are built into the peripheral). Also, the host software doesn't need to deal with distributed auto-configuration since the pre-designated master node manages all that.

Kernel developers added USB support to Linux early in the 2.2 kernel series and have been developing it further since then. Besides support for each new generation of USB, various host controllers gained support, new drivers for peripherals have been added and advanced features for latency measurement and improved power management introduced.

Linux can run inside USB devices as well as on the hosts that control the devices. But USB device drivers running inside those peripherals don't do the same things as the ones running inside hosts, so they've been given a different name: gadget drivers. This document does not cover gadget drivers.

20.1.2 USB Host-Side API Model

Host-side drivers for USB devices talk to the "usbcore" APIs. There are two. One is intended for general-purpose drivers (exposed through driver frameworks), and the other is for drivers that are part of the core. Such core drivers include the hub driver (which manages trees of USB devices) and several different kinds of host controller drivers, which control individual busses.

The device model seen by USB drivers is relatively complex.

- USB supports four kinds of data transfers (control, bulk, interrupt, and isochronous). Two of them (control and bulk) use bandwidth as it's avail-

able, while the other two (interrupt and isochronous) are scheduled to provide guaranteed bandwidth.

- The device description model includes one or more "configurations" per device, only one of which is active at a time. Devices are supposed to be capable of operating at lower than their top speeds and may provide a BOS descriptor showing the lowest speed they remain fully operational at.
- From USB 3.0 on configurations have one or more "functions", which provide a common functionality and are grouped together for purposes of power management.
- Configurations or functions have one or more "interfaces", each of which may have "alternate settings". Interfaces may be standardized by USB "Class" specifications, or may be specific to a vendor or device.

  USB device drivers actually bind to interfaces, not devices. Think of them as "interface drivers", though you may not see many devices where the distinction is important. Most USB devices are simple, with only one function, one configuration, one interface, and one alternate setting.
- Interfaces have one or more "endpoints", each of which supports one type and direction of data transfer such as "bulk out" or "interrupt in". The entire configuration may have up to sixteen endpoints in each direction, allocated as needed among all the interfaces.
- Data transfer on USB is packetized; each endpoint has a maximum packet size. Drivers must often be aware of conventions such as flagging the end of bulk transfers using "short" (including zero length) packets.
- The Linux USB API supports synchronous calls for control and bulk messages. It also supports asynchronous calls for all kinds of data transfer, using request structures called "URBs" (USB Request Blocks).

Accordingly, the USB Core API exposed to device drivers covers quite a lot of territory. You'll probably need to consult the USB 3.0 specification, available online from www.usb.org at no cost, as well as class or device specifications.

The only host-side drivers that actually touch hardware (reading/writing registers, handling IRQs, and so on) are the HCDs. In theory, all HCDs provide the same functionality through the same API. In practice, that's becoming more true, but there are still differences that crop up especially with fault handling on the less common controllers. Different controllers don't necessarily report the same aspects of failures, and recovery from faults (including software-induced ones like unlinking an URB) isn't yet fully consistent. Device driver authors should make a point of doing disconnect testing (while the device is active) with each different host controller driver, to make sure drivers don't have bugs of their own as well as to make sure they aren't relying on some HCD-specific behavior.

20.1.3 USB-Standard Types

In <linux/usb/ch9.h> you will find the USB data types defined in chapter 9 of the USB specification. These data types are used throughout USB, and in APIs including this host side API, gadget APIs, usb character devices and debugfs interfaces.

const char * **usb_ep_type_string**(int ep_type)
Returns human readable-name of the endpoint type.

Parameters

int ep_type The endpoint type to return human-readable name for. If it's not any of the types: USB_ENDPOINT_XFER_{CONTROL, ISOC, BULK, INT}, usually got by usb_endpoint_type(), the string 'unknown' will be returned.

const char * **usb_speed_string**(enum usb_device_speed speed)
Returns human readable-name of the speed.

Parameters

enum usb_device_speed speed The speed to return human-readable name for. If it's not any of the speeds defined in usb_device_speed enum, string for USB_SPEED_UNKNOWN will be returned.

enum usb_device_speed **usb_get_maximum_speed**(struct device * dev)
Get maximum requested speed for a given USB controller.

Parameters

struct device * dev Pointer to the given USB controller device

Description

The function gets the maximum speed string from property "maximum-speed", and returns the corresponding enum usb_device_speed.

const char * **usb_state_string**(enum usb_device_state state)
Returns human readable name for the state.

Parameters

enum usb_device_state state The state to return a human-readable name for. If it's not any of the states devices in usb_device_state_string enum, the string UNKNOWN will be returned.

const char * **usb_decode_ctrl**(char * str, size_t size, __u8 bRequestType, __u8 bRequest, __u16 wValue, __u16 wIndex, __u16 wLength)
Returns human readable representation of control request.

Parameters

char * str buffer to return a human-readable representation of control request. This buffer should have about 200 bytes.

size_t size size of str buffer.

__u8 bRequestType matches the USB bmRequestType field

__u8 bRequest matches the USB bRequest field

__u16 wValue matches the USB wValue field (CPU byte order)

__u16 wIndex matches the USB wIndex field (CPU byte order)

__u16 wLength matches the USB wLength field (CPU byte order)

Description

Function returns decoded, formatted and human-readable description of control request packet.

The usage scenario for this is for tracepoints, so function as a return use the same value as in parameters. This approach allows to use this function in TP_printk

Important: wValue, wIndex, wLength parameters before invoking this function should be processed by le16_to_cpu macro.

20.1.4 Host-Side Data Types and Macros

The host side API exposes several layers to drivers, some of which are more necessary than others. These support lifecycle models for host side drivers and devices, and support passing buffers through usbcore to some HCD that performs the I/O for the device driver.

struct **usb_host_endpoint**
host-side endpoint descriptor and queue

Definition

```
struct usb_host_endpoint {
  struct usb_endpoint_descriptor          desc;
  struct usb_ss_ep_comp_descriptor        ss_ep_comp;
  struct usb_ssp_isoc_ep_comp_descriptor  ssp_isoc_ep_comp;
  struct list_head                urb_list;
  void *hcpriv;
  struct ep_device                *ep_dev;
  unsigned char *extra;
  int extralen;
  int enabled;
  int streams;
};
```

Members

desc descriptor for this endpoint, wMaxPacketSize in native byteorder

ss_ep_comp SuperSpeed companion descriptor for this endpoint

ssp_isoc_ep_comp SuperSpeedPlus isoc companion descriptor for this endpoint

urb_list urbs queued to this endpoint; maintained by usbcore

hcpriv for use by HCD; typically holds hardware dma queue head (QH) with one or more transfer descriptors (TDs) per urb

ep_dev ep_device for sysfs info

extra descriptors following this endpoint in the configuration

extralen how many bytes of “extra” are valid

enabled URBs may be submitted to this endpoint

streams number of USB-3 streams allocated on the endpoint

Description

USB requests are always queued to a given endpoint, identified by a descriptor within an active interface in a given USB configuration.

struct **usb_interface**
what usb device drivers talk to

Definition

```
struct usb_interface {
  struct usb_host_interface *altsetting;
  struct usb_host_interface *cur_altsetting;
  unsigned num_altsetting;
  struct usb_interface_assoc_descriptor *intf_assoc;
  int minor;
  enum usb_interface_condition condition;
  unsigned sysfs_files_created:1;
  unsigned ep_devs_created:1;
  unsigned unregistering:1;
  unsigned needs_remote_wakeup:1;
  unsigned needs_altsetting0:1;
  unsigned needs_binding:1;
  unsigned resetting_device:1;
  unsigned authorized:1;
  struct device dev;
  struct device *usb_dev;
  struct work_struct reset_ws;
};
```

Members

altsetting array of interface structures, one for each alternate setting that may be selected. Each one includes a set of endpoint configurations. They will be in no particular order.

cur_altsetting the current altsetting.

num_altsetting number of altsettings defined.

intf_assoc interface association descriptor

minor the minor number assigned to this interface, if this interface is bound to a driver that uses the USB major number. If this interface does not use the USB major, this field should be unused. The driver should set this value in the probe() function of the driver, after it has been assigned a minor number from the USB core by calling `usb_register_dev()`.

condition binding state of the interface: not bound, binding (in probe()), bound to a driver, or unbinding (in disconnect())

sysfs_files_created sysfs attributes exist

ep_devs_created endpoint child pseudo-devices exist

unregistering flag set when the interface is being unregistered

needs_remote_wakeup flag set when the driver requires remote-wakeup capability during autosuspend.

needs_altsetting0 flag set when a set-interface request for altsetting 0 has been deferred.

needs_binding flag set when the driver should be re-probed or unbound following a reset or suspend operation it doesn't support.

resetting_device USB core reset the device, so use alt setting 0 as current; needs bandwidth alloc after reset.

authorized This allows to (de)authorize individual interfaces instead a whole device in contrast to the device authorization.

dev driver model's view of this device

usb_dev if an interface is bound to the USB major, this will point to the sysfs representation for that device.

reset_ws Used for scheduling resets from atomic context.

Description

USB device drivers attach to interfaces on a physical device. Each interface encapsulates a single high level function, such as feeding an audio stream to a speaker or reporting a change in a volume control. Many USB devices only have one interface. The protocol used to talk to an interface's endpoints can be defined in a usb "class" specification, or by a product's vendor. The (default) control endpoint is part of every interface, but is never listed among the interface's descriptors.

The driver that is bound to the interface can use standard driver model calls such as dev_get_drvdata() on the dev member of this structure.

Each interface may have alternate settings. The initial configuration of a device sets altsetting 0, but the device driver can change that setting using `usb_set_interface()`. Alternate settings are often used to control the use of periodic endpoints, such as by having different endpoints use different amounts of reserved USB bandwidth. All standards-conformant USB devices that use isochronous endpoints will use them in non-default settings.

The USB specification says that alternate setting numbers must run from 0 to one less than the total number of alternate settings. But some devices manage to mess this up, and the structures aren't necessarily stored in numerical order anyhow. Use `usb_altnum_to_altsetting()` to look up an alternate setting in the altsetting array based on its number.

struct **usb_interface_cache**
long-term representation of a device interface

Definition

```
struct usb_interface_cache {
  unsigned num_altsetting;
  struct kref ref;
  struct usb_host_interface altsetting[];
};
```

Members

num_altsetting number of altsettings defined.

ref reference counter.

altsetting variable-length array of interface structures, one for each alternate setting that may be selected. Each one includes a set of endpoint configurations. They will be in no particular order.

Description

These structures persist for the lifetime of a usb_device, unlike struct usb_interface (which persists only as long as its configuration is installed). The altsetting arrays can be accessed through these structures at any time, permitting comparison of configurations and providing support for the /sys/kernel/debug/usb/devices pseudo-file.

struct **usb_host_config**
representation of a device's configuration

Definition

```
struct usb_host_config {
  struct usb_config_descriptor    desc;
  char *string;
  struct usb_interface_assoc_descriptor *intf_assoc[USB_MAXIADS];
  struct usb_interface *interface[USB_MAXINTERFACES];
  struct usb_interface_cache *intf_cache[USB_MAXINTERFACES];
  unsigned char *extra;
  int extralen;
};
```

Members

desc the device's configuration descriptor.

string pointer to the cached version of the iConfiguration string, if present for this configuration.

intf_assoc list of any interface association descriptors in this config

interface array of pointers to usb_interface structures, one for each interface in the configuration. The number of interfaces is stored in desc.bNumInterfaces. These pointers are valid only while the the configuration is active.

intf_cache array of pointers to usb_interface_cache structures, one for each interface in the configuration. These structures exist for the entire life of the device.

extra pointer to buffer containing all extra descriptors associated with this configuration (those preceding the first interface descriptor).

extralen length of the extra descriptors buffer.

Description

USB devices may have multiple configurations, but only one can be active at any time. Each encapsulates a different operational environment; for example, a dual-speed device would have separate configurations for full-speed and high-speed

operation. The number of configurations available is stored in the device descriptor as bNumConfigurations.

A configuration can contain multiple interfaces. Each corresponds to a different function of the USB device, and all are available whenever the configuration is active. The USB standard says that interfaces are supposed to be numbered from 0 to desc.bNumInterfaces-1, but a lot of devices get this wrong. In addition, the interface array is not guaranteed to be sorted in numerical order. Use `usb_ifnum_to_if()` to look up an interface entry based on its number.

Device drivers should not attempt to activate configurations. The choice of which configuration to install is a policy decision based on such considerations as available power, functionality provided, and the user's desires (expressed through userspace tools). However, drivers can call `usb_reset_configuration()` to reinitialize the current configuration and all its interfaces.

struct **usb_device**
kernel's representation of a USB device

Definition

```
struct usb_device {
  int devnum;
  char devpath[16];
  u32 route;
  enum usb_device_state   state;
  enum usb_device_speed   speed;
  unsigned int            rx_lanes;
  unsigned int            tx_lanes;
  struct usb_tt   *tt;
  int ttport;
  unsigned int toggle[2];
  struct usb_device *parent;
  struct usb_bus *bus;
  struct usb_host_endpoint ep0;
  struct device dev;
  struct usb_device_descriptor descriptor;
  struct usb_host_bos *bos;
  struct usb_host_config *config;
  struct usb_host_config *actconfig;
  struct usb_host_endpoint *ep_in[16];
  struct usb_host_endpoint *ep_out[16];
  char **rawdescriptors;
  unsigned short bus_mA;
  u8 portnum;
  u8 level;
  u8 devaddr;
  unsigned can_submit:1;
  unsigned persist_enabled:1;
  unsigned have_langid:1;
  unsigned authorized:1;
  unsigned authenticated:1;
  unsigned wusb:1;
  unsigned lpm_capable:1;
  unsigned usb2_hw_lpm_capable:1;
  unsigned usb2_hw_lpm_besl_capable:1;
  unsigned usb2_hw_lpm_enabled:1;
```

(continues on next page)

(continued from previous page)

```
  unsigned usb2_hw_lpm_allowed:1;
  unsigned usb3_lpm_u1_enabled:1;
  unsigned usb3_lpm_u2_enabled:1;
  int string_langid;
  char *product;
  char *manufacturer;
  char *serial;
  struct list_head filelist;
  int maxchild;
  u32 quirks;
  atomic_t urbnum;
  unsigned long active_duration;
#ifdef CONFIG_PM;
  unsigned long connect_time;
  unsigned do_remote_wakeup:1;
  unsigned reset_resume:1;
  unsigned port_is_suspended:1;
#endif;
  struct wusb_dev *wusb_dev;
  int slot_id;
  enum usb_device_removable removable;
  struct usb2_lpm_parameters l1_params;
  struct usb3_lpm_parameters u1_params;
  struct usb3_lpm_parameters u2_params;
  unsigned lpm_disable_count;
  u16 hub_delay;
  unsigned use_generic_driver:1;
};
```

Members

devnum device number; address on a USB bus

devpath device ID string for use in messages (e.g., /port/…)

route tree topology hex string for use with xHCI

state device state: configured, not attached, etc.

speed device speed: high/full/low (or error)

rx_lanes number of rx lanes in use, USB 3.2 adds dual-lane support

tx_lanes number of tx lanes in use, USB 3.2 adds dual-lane support

tt Transaction Translator info; used with low/full speed dev, highspeed hub

ttport device port on that tt hub

toggle one bit for each endpoint, with ([0] = IN, [1] = OUT) endpoints

parent our hub, unless we’re the root

bus bus we’re part of

ep0 endpoint 0 data (default control pipe)

dev generic device interface

descriptor USB device descriptor

bos USB device BOS descriptor set

config all of the device's configs

actconfig the active configuration

ep_in array of IN endpoints

ep_out array of OUT endpoints

rawdescriptors raw descriptors for each config

bus_mA Current available from the bus

portnum parent port number (origin 1)

level number of USB hub ancestors

devaddr device address, XHCI: assigned by HW, others: same as devnum

can_submit URBs may be submitted

persist_enabled USB_PERSIST enabled for this device

have_langid whether string_langid is valid

authorized policy has said we can use it; (user space) policy determines if we authorize this device to be used or not. By default, wired USB devices are authorized. WUSB devices are not, until we authorize them from user space. FIXME – complete doc

authenticated Crypto authentication passed

wusb device is Wireless USB

lpm_capable device supports LPM

usb2_hw_lpm_capable device can perform USB2 hardware LPM

usb2_hw_lpm_besl_capable device can perform USB2 hardware BESL LPM

usb2_hw_lpm_enabled USB2 hardware LPM is enabled

usb2_hw_lpm_allowed Userspace allows USB 2.0 LPM to be enabled

usb3_lpm_u1_enabled USB3 hardware U1 LPM enabled

usb3_lpm_u2_enabled USB3 hardware U2 LPM enabled

string_langid language ID for strings

product iProduct string, if present (static)

manufacturer iManufacturer string, if present (static)

serial iSerialNumber string, if present (static)

filelist usbfs files that are open to this device

maxchild number of ports if hub

quirks quirks of the whole device

urbnum number of URBs submitted for the whole device

active_duration total time device is not suspended

connect_time time device was first connected

do_remote_wakeup remote wakeup should be enabled

reset_resume needs reset instead of resume

port_is_suspended the upstream port is suspended (L2 or U3)

wusb_dev if this is a Wireless USB device, link to the WUSB specific data for the device.

slot_id Slot ID assigned by xHCI

removable Device can be physically removed from this port

l1_params best effor service latency for USB2 L1 LPM state, and L1 timeout.

u1_params exit latencies for USB3 U1 LPM state, and hub-initiated timeout.

u2_params exit latencies for USB3 U2 LPM state, and hub-initiated timeout.

lpm_disable_count Ref count used by usb_disable_lpm() and usb_enable_lpm() to keep track of the number of functions that require USB 3.0 Link Power Management to be disabled for this usb_device. This count should only be manipulated by those functions, with the bandwidth_mutex is held.

hub_delay cached value consisting of: parent->hub_delay + wHubDelay + tTPTransmissionDelay (40ns)

Will be used as wValue for SetIsochDelay requests.

Notes

Usbcore drivers should not set usbdev->state directly. Instead use `usb_set_device_state()`.

usb_hub_for_each_child(hdev, port1, child)
iterate over all child devices on the hub

Parameters

hdev USB device belonging to the usb hub

port1 portnum associated with child device

child child device pointer

int **usb_interface_claimed**(struct usb_interface * iface)
returns true iff an interface is claimed

Parameters

struct usb_interface * iface the interface being checked

Return

`true` (nonzero) iff the interface is claimed, else `false` (zero).

Note

Callers must own the driver model's usb bus readlock. So driver probe() entries don't need extra locking, but other call contexts may need to explicitly claim that lock.

int **usb_make_path**(struct usb_device * dev, char * buf, size_t size)
returns stable device path in the usb tree

Parameters

struct usb_device * dev the device whose path is being constructed

char * buf where to put the string

size_t size how big is "buf"?

Return

Length of the string (> 0) or negative if size was too small.

Note

This identifier is intended to be "stable", reflecting physical paths in hardware such as physical bus addresses for host controllers or ports on USB hubs. That makes it stay the same until systems are physically reconfigured, by re-cabling a tree of USB devices or by moving USB host controllers. Adding and removing devices, including virtual root hubs in host controller driver modules, does not change these path identifiers; neither does rebooting or re-enumerating. These are more useful identifiers than changeable ("unstable") ones like bus numbers or device addresses.

Description

With a partial exception for devices connected to USB 2.0 root hubs, these identifiers are also predictable. So long as the device tree isn't changed, plugging any USB device into a given hub port always gives it the same path. Because of the use of "companion" controllers, devices connected to ports on USB 2.0 root hubs (EHCI host controllers) will get one path ID if they are high speed, and a different one if they are full or low speed.

USB_DEVICE(vend, prod)
macro used to describe a specific usb device

Parameters

vend the 16 bit USB Vendor ID

prod the 16 bit USB Product ID

Description

This macro is used to create a struct usb_device_id that matches a specific device.

USB_DEVICE_VER(vend, prod, lo, hi)
describe a specific usb device with a version range

Parameters

vend the 16 bit USB Vendor ID

prod the 16 bit USB Product ID

lo the bcdDevice_lo value

hi the bcdDevice_hi value

Description

This macro is used to create a struct usb_device_id that matches a specific device, with a version range.

USB_DEVICE_INTERFACE_CLASS(vend, prod, cl)
describe a usb device with a specific interface class

Parameters

vend the 16 bit USB Vendor ID

prod the 16 bit USB Product ID

cl bInterfaceClass value

Description

This macro is used to create a struct usb_device_id that matches a specific interface class of devices.

USB_DEVICE_INTERFACE_PROTOCOL(vend, prod, pr)
describe a usb device with a specific interface protocol

Parameters

vend the 16 bit USB Vendor ID

prod the 16 bit USB Product ID

pr bInterfaceProtocol value

Description

This macro is used to create a struct usb_device_id that matches a specific interface protocol of devices.

USB_DEVICE_INTERFACE_NUMBER(vend, prod, num)
describe a usb device with a specific interface number

Parameters

vend the 16 bit USB Vendor ID

prod the 16 bit USB Product ID

num bInterfaceNumber value

Description

This macro is used to create a struct usb_device_id that matches a specific interface number of devices.

USB_DEVICE_INFO(cl, sc, pr)
macro used to describe a class of usb devices

Parameters

cl bDeviceClass value

sc bDeviceSubClass value

pr bDeviceProtocol value

Description

This macro is used to create a struct usb_device_id that matches a specific class of devices.

USB_INTERFACE_INFO(cl, sc, pr)
macro used to describe a class of usb interfaces

Parameters

cl bInterfaceClass value

sc bInterfaceSubClass value

pr bInterfaceProtocol value

Description

This macro is used to create a struct usb_device_id that matches a specific class of interfaces.

USB_DEVICE_AND_INTERFACE_INFO(vend, prod, cl, sc, pr)
describe a specific usb device with a class of usb interfaces

Parameters

vend the 16 bit USB Vendor ID

prod the 16 bit USB Product ID

cl bInterfaceClass value

sc bInterfaceSubClass value

pr bInterfaceProtocol value

Description

This macro is used to create a struct usb_device_id that matches a specific device with a specific class of interfaces.

This is especially useful when explicitly matching devices that have vendor specific bDeviceClass values, but standards-compliant interfaces.

USB_VENDOR_AND_INTERFACE_INFO(vend, cl, sc, pr)
describe a specific usb vendor with a class of usb interfaces

Parameters

vend the 16 bit USB Vendor ID

cl bInterfaceClass value

sc bInterfaceSubClass value

pr bInterfaceProtocol value

Description

This macro is used to create a struct usb_device_id that matches a specific vendor with a specific class of interfaces.

This is especially useful when explicitly matching devices that have vendor specific bDeviceClass values, but standards-compliant interfaces.

struct **usbdrv_wrap**
wrapper for driver-model structure

Definition

```
struct usbdrv_wrap {
  struct device_driver driver;
  int for_devices;
};
```

Members

driver The driver-model core driver structure.

for_devices Non-zero for device drivers, 0 for interface drivers.

struct **usb_driver**
identifies USB interface driver to usbcore

Definition

```
struct usb_driver {
  const char *name;
  int (*probe) (struct usb_interface *intf, const struct usb_device_id␣
↪*id);
  void (*disconnect) (struct usb_interface *intf);
  int (*unlocked_ioctl) (struct usb_interface *intf, unsigned int code,␣
↪void *buf);
  int (*suspend) (struct usb_interface *intf, pm_message_t message);
  int (*resume) (struct usb_interface *intf);
  int (*reset_resume)(struct usb_interface *intf);
  int (*pre_reset)(struct usb_interface *intf);
  int (*post_reset)(struct usb_interface *intf);
  const struct usb_device_id *id_table;
  const struct attribute_group **dev_groups;
  struct usb_dynids dynids;
  struct usbdrv_wrap drvwrap;
  unsigned int no_dynamic_id:1;
  unsigned int supports_autosuspend:1;
  unsigned int disable_hub_initiated_lpm:1;
  unsigned int soft_unbind:1;
};
```

Members

name The driver name should be unique among USB drivers, and should normally be the same as the module name.

probe Called to see if the driver is willing to manage a particular interface on a device. If it is, probe returns zero and uses usb_set_intfdata() to associate driver-specific data with the interface. It may also use `usb_set_interface()` to specify the appropriate altsetting. If unwilling to manage the interface, return -ENODEV, if genuine IO errors occurred, an appropriate negative errno value.

disconnect Called when the interface is no longer accessible, usually because its device has been (or is being) disconnected or the driver module is being unloaded.

unlocked_ioctl Used for drivers that want to talk to userspace through the "usbfs" filesystem. This lets devices provide ways to expose information to user space regardless of where they do (or don't) show up otherwise in the filesystem.

suspend Called when the device is going to be suspended by the system either from system sleep or runtime suspend context. The return value will be ignored in system sleep context, so do NOT try to continue using the device if suspend fails in this case. Instead, let the resume or reset-resume routine recover from the failure.

resume Called when the device is being resumed by the system.

reset_resume Called when the suspended device has been reset instead of being resumed.

pre_reset Called by `usb_reset_device()` when the device is about to be reset. This routine must not return until the driver has no active URBs for the device, and no more URBs may be submitted until the post_reset method is called.

post_reset Called by `usb_reset_device()` after the device has been reset

id_table USB drivers use ID table to support hotplugging. Export this with MODULE_DEVICE_TABLE(usb,⋯). This must be set or your driver's probe function will never get called.

dev_groups Attributes attached to the device that will be created once it is bound to the driver.

dynids used internally to hold the list of dynamically added device ids for this driver.

drvwrap Driver-model core structure wrapper.

no_dynamic_id if set to 1, the USB core will not allow dynamic ids to be added to this driver by preventing the sysfs file from being created.

supports_autosuspend if set to 0, the USB core will not allow autosuspend for interfaces bound to this driver.

disable_hub_initiated_lpm if set to 1, the USB core will not allow hubs to initiate lower power link state transitions when an idle timeout occurs. Device-initiated USB 3.0 link PM will still be allowed.

soft_unbind if set to 1, the USB core will not kill URBs and disable endpoints before calling the driver's disconnect method.

Description

USB interface drivers must provide a name, probe() and disconnect() methods, and an id_table. Other driver fields are optional.

The id_table is used in hotplugging. It holds a set of descriptors, and specialized data may be associated with each entry. That table is used by both user and kernel mode hotplugging support.

The probe() and disconnect() methods are called in a context where they can sleep, but they should avoid abusing the privilege. Most work to connect to a device should be done when the device is opened, and undone at the last close. The disconnect code needs to address concurrency issues with respect to open() and

close() methods, as well as forcing all pending I/O requests to complete (by unlinking them as necessary, and blocking until the unlinks complete).

struct **usb_device_driver**
identifies USB device driver to usbcore

Definition

```
struct usb_device_driver {
  const char *name;
  bool (*match) (struct usb_device *udev);
  int (*probe) (struct usb_device *udev);
  void (*disconnect) (struct usb_device *udev);
  int (*suspend) (struct usb_device *udev, pm_message_t message);
  int (*resume) (struct usb_device *udev, pm_message_t message);
  const struct attribute_group **dev_groups;
  struct usbdrv_wrap drvwrap;
  const struct usb_device_id *id_table;
  unsigned int supports_autosuspend:1;
  unsigned int generic_subclass:1;
};
```

Members

name The driver name should be unique among USB drivers, and should normally be the same as the module name.

probe Called to see if the driver is willing to manage a particular device. If it is, probe returns zero and uses dev_set_drvdata() to associate driver-specific data with the device. If unwilling to manage the device, return a negative errno value.

disconnect Called when the device is no longer accessible, usually because it has been (or is being) disconnected or the driver's module is being unloaded.

suspend Called when the device is going to be suspended by the system.

resume Called when the device is being resumed by the system.

dev_groups Attributes attached to the device that will be created once it is bound to the driver.

drvwrap Driver-model core structure wrapper.

supports_autosuspend if set to 0, the USB core will not allow autosuspend for devices bound to this driver.

generic_subclass if set to 1, the generic USB driver's probe, disconnect, resume and suspend functions will be called in addition to the driver's own, so this part of the setup does not need to be replicated.

Description

USB drivers must provide all the fields listed above except drvwrap.

struct **usb_class_driver**
identifies a USB driver that wants to use the USB major number

Definition

```
struct usb_class_driver {
  char *name;
  char *(*devnode)(struct device *dev, umode_t *mode);
  const struct file_operations *fops;
  int minor_base;
};
```

Members

name the usb class device name for this driver. Will show up in sysfs.

devnode Callback to provide a naming hint for a possible device node to create.

fops pointer to the struct file_operations of this driver.

minor_base the start of the minor range for this driver.

Description

This structure is used for the `usb_register_dev()` and `usb_deregister_dev()` functions, to consolidate a number of the parameters used for them.

module_usb_driver(__usb_driver)
Helper macro for registering a USB driver

Parameters

__usb_driver usb_driver struct

Description

Helper macro for USB drivers which do not do anything special in module init/exit. This eliminates a lot of boilerplate. Each module may only use this macro once, and calling it replaces `module_init()` and `module_exit()`

struct **urb**
USB Request Block

Definition

```

Members

urb_list For use by current owner of the URB.

anchor_list membership in the list of an anchor

anchor to anchor URBs to a common mooring

dev Identifies the USB device to perform the request.

ep Points to the endpoint's data structure. Will eventually replace **pipe**.

pipe Holds endpoint number, direction, type, and more. Create these values with the eight macros available; usb_{snd,rcv}TYPEpipe(dev,endpoint), where the TYPE is "ctrl" (control), "bulk", "int" (interrupt), or "iso" (isochronous). For example usb_sndbulkpipe() or usb_rcvintpipe(). Endpoint numbers range from zero to fifteen. Note that "in" endpoint two is a different endpoint (and pipe) from "out" endpoint two. The current configuration controls the existence, type, and maximum packet size of any given endpoint.

stream_id the endpoint's stream ID for bulk streams

status This is read in non-iso completion functions to get the status of the particular request. ISO requests only use it to tell whether the URB was unlinked; detailed status for each frame is in the fields of the iso_frame-desc.

transfer_flags A variety of flags may be used to affect how URB submission, unlinking, or operation are handled. Different kinds of URB can use different flags.

transfer_buffer This identifies the buffer to (or from) which the I/O request will be performed unless URB_NO_TRANSFER_DMA_MAP is set (however, do not leave garbage in transfer_buffer even then). This buffer must be suitable for DMA; allocate it with kmalloc() or equivalent. For transfers to "in" endpoints, contents of this buffer will be modified. This buffer is used for the data stage of control transfers.

transfer_dma When transfer_flags includes URB_NO_TRANSFER_DMA_MAP, the device driver is saying that it provided this DMA address, which the host controller driver should use in preference to the transfer_buffer.

sg scatter gather buffer list, the buffer size of each element in the list (except the last) must be divisible by the endpoint's max packet size if no_sg_constraint isn't set in 'struct usb_bus'

num_mapped_sgs (internal) number of mapped sg entries

num_sgs number of entries in the sg list

transfer_buffer_length How big is transfer_buffer. The transfer may be broken up into chunks according to the current maximum packet size for the endpoint, which is a function of the configuration and is encoded in the pipe. When the length is zero, neither transfer_buffer nor transfer_dma is used.

actual_length This is read in non-iso completion functions, and it tells how many bytes (out of transfer_buffer_length) were transferred. It will normally be the same as requested, unless either an error was reported or a short read was performed. The URB_SHORT_NOT_OK transfer flag may be used to make such short reads be reported as errors.

setup_packet Only used for control transfers, this points to eight bytes of setup data. Control transfers always start by sending this data to the device. Then transfer_buffer is read or written, if needed.

setup_dma DMA pointer for the setup packet. The caller must not use this field; setup_packet must point to a valid buffer.

start_frame Returns the initial frame for isochronous transfers.

number_of_packets Lists the number of ISO transfer buffers.

interval Specifies the polling interval for interrupt or isochronous transfers. The units are frames (milliseconds) for full and low speed devices, and microframes (1/8 millisecond) for highspeed and SuperSpeed devices.

error_count Returns the number of ISO transfers that reported errors.

context For use in completion functions. This normally points to request-specific driver context.

complete Completion handler. This URB is passed as the parameter to the completion function. The completion function may then do what it likes with the URB, including resubmitting or freeing it.

iso_frame_desc Used to provide arrays of ISO transfer buffers and to collect the transfer status for each buffer.

Description

This structure identifies USB transfer requests. URBs must be allocated by calling `usb_alloc_urb()` and freed with a call to `usb_free_urb()`. Initialization may be done using various usb_fill_*_urb() functions. URBs are submitted using `usb_submit_urb()`, and pending requests may be canceled using `usb_unlink_urb()` or `usb_kill_urb()`.

Data Transfer Buffers:

Normally drivers provide I/O buffers allocated with kmalloc() or otherwise taken from the general page pool. That is provided by transfer_buffer (control requests also use setup_packet), and host controller drivers perform a dma mapping (and unmapping) for each buffer transferred. Those mapping operations can be expensive on some platforms (perhaps using a dma bounce buffer or talking to an IOMMU), although they' re cheap on commodity x86 and ppc hardware.

Alternatively, drivers may pass the URB_NO_TRANSFER_DMA_MAP transfer flag, which tells the host controller driver that no such mapping is needed for the transfer_buffer since the device driver is DMA-aware. For example, a device driver might allocate a DMA buffer with `usb_alloc_coherent()` or call usb_buffer_map().

When this transfer flag is provided, host controller drivers will attempt to use the dma address found in the transfer_dma field rather than determining a dma address themselves.

Note that transfer_buffer must still be set if the controller does not support DMA (as indicated by hcd_uses_dma()) and when talking to root hub. If you have to trasfer between highmem zone and the device on such controller, create a bounce buffer or bail out with an error. If transfer_buffer cannot be set (is in highmem) and the controller is DMA capable, assign NULL to it, so that usbmon knows not to use the value. The setup_packet must always be set, so it cannot be located in highmem.

Initialization:

All URBs submitted must initialize the dev, pipe, transfer_flags (may be zero), and complete fields. All URBs must also initialize transfer_buffer and transfer_buffer_length. They may provide the URB_SHORT_NOT_OK transfer flag, indicating that short reads are to be treated as errors; that flag is invalid for write requests.

Bulk URBs may use the URB_ZERO_PACKET transfer flag, indicating that bulk OUT transfers should always terminate with a short packet, even if it means adding an extra zero length packet.

Control URBs must provide a valid pointer in the setup_packet field. Unlike the transfer_buffer, the setup_packet may not be mapped for DMA beforehand.

Interrupt URBs must provide an interval, saying how often (in milliseconds or, for highspeed devices, 125 microsecond units) to poll for transfers. After the URB has been submitted, the interval field reflects how the transfer was actually scheduled. The polling interval may be more frequent than requested. For example, some controllers have a maximum interval of 32 milliseconds, while others support intervals of up to 1024 milliseconds. Isochronous URBs also have transfer intervals. (Note that for isochronous endpoints, as well as high speed interrupt endpoints, the encoding of the transfer interval in the endpoint descriptor is logarithmic. Device drivers must convert that value to linear units themselves.)

If an isochronous endpoint queue isn't already running, the host controller will schedule a new URB to start as soon as bandwidth utilization allows. If the queue is running then a new URB will be scheduled to start in the first transfer slot following the end of the preceding URB, if that slot has not already expired. If the slot has expired (which can happen when IRQ delivery is delayed for a long time), the scheduling behavior depends on the URB_ISO_ASAP flag. If the flag is clear then the URB will be scheduled to start in the expired slot, implying that some of its packets will not be transferred; if the flag is set then the URB will be scheduled in the first unexpired slot, breaking the queue's synchronization. Upon URB completion, the start_frame field will be set to the (micro)frame number in which the transfer was scheduled. Ranges for frame counter values are HC-specific and can go from as low as 256 to as high as 65536 frames.

Isochronous URBs have a different data transfer model, in part because the quality of service is only "best effort". Callers provide specially allocated URBs, with number_of_packets worth of iso_frame_desc structures at the end. Each such packet is an individual ISO transfer. Isochronous URBs are normally queued, submitted by drivers to arrange that transfers are at least double buffered, and then explicitly

resubmitted in completion handlers, so that data (such as audio or video) streams at as constant a rate as the host controller scheduler can support.

Completion Callbacks:

The completion callback is made in_interrupt(), and one of the first things that a completion handler should do is check the status field. The status field is provided for all URBs. It is used to report unlinked URBs, and status for all non-ISO transfers. It should not be examined before the URB is returned to the completion handler.

The context field is normally used to link URBs back to the relevant driver or request state.

When the completion callback is invoked for non-isochronous URBs, the actual_length field tells how many bytes were transferred. This field is updated even when the URB terminated with an error or was unlinked.

ISO transfer status is reported in the status and actual_length fields of the iso_frame_desc array, and the number of errors is reported in error_count. Completion callbacks for ISO transfers will normally (re)submit URBs to ensure a constant transfer rate.

Note that even fields marked "public" should not be touched by the driver when the urb is owned by the hcd, that is, since the call to `usb_submit_urb()` till the entry into the completion routine.

void **usb_fill_control_urb**(struct urb * urb, struct usb_device * dev, unsigned int pipe, unsigned char * setup_packet, void * transfer_buffer, int buffer_length, usb_complete_t complete_fn, void * context)

initializes a control urb

Parameters

struct urb * urb pointer to the urb to initialize.

struct usb_device * dev pointer to the struct usb_device for this urb.

unsigned int pipe the endpoint pipe

unsigned char * setup_packet pointer to the setup_packet buffer

void * transfer_buffer pointer to the transfer buffer

int buffer_length length of the transfer buffer

usb_complete_t complete_fn pointer to the usb_complete_t function

void * context what to set the urb context to.

Description

Initializes a control urb with the proper information needed to submit it to a device.

void **usb_fill_bulk_urb**(struct urb * urb, struct usb_device * dev, unsigned int pipe, void * transfer_buffer, int buffer_length, usb_complete_t complete_fn, void * context)

macro to help initialize a bulk urb

Parameters

struct urb * urb pointer to the urb to initialize.

struct usb_device * dev pointer to the struct usb_device for this urb.

unsigned int pipe the endpoint pipe

void * transfer_buffer pointer to the transfer buffer

int buffer_length length of the transfer buffer

usb_complete_t complete_fn pointer to the usb_complete_t function

void * context what to set the urb context to.

Description

Initializes a bulk urb with the proper information needed to submit it to a device.

void **usb_fill_int_urb**(struct urb * urb, struct usb_device * dev, unsigned int pipe, void * transfer_buffer, int buffer_length, usb_complete_t complete_fn, void * context, int interval)
macro to help initialize a interrupt urb

Parameters

struct urb * urb pointer to the urb to initialize.

struct usb_device * dev pointer to the struct usb_device for this urb.

unsigned int pipe the endpoint pipe

void * transfer_buffer pointer to the transfer buffer

int buffer_length length of the transfer buffer

usb_complete_t complete_fn pointer to the usb_complete_t function

void * context what to set the urb context to.

int interval what to set the urb interval to, encoded like the endpoint descriptor's bInterval value.

Description

Initializes a interrupt urb with the proper information needed to submit it to a device.

Note that High Speed and SuperSpeed(+) interrupt endpoints use a logarithmic encoding of the endpoint interval, and express polling intervals in microframes (eight per millisecond) rather than in frames (one per millisecond).

Wireless USB also uses the logarithmic encoding, but specifies it in units of 128us instead of 125us. For Wireless USB devices, the interval is passed through to the host controller, rather than being translated into microframe units.

int **usb_urb_dir_in**(struct urb * urb)
check if an URB describes an IN transfer

Parameters

struct urb * urb URB to be checked

Return

1 if **urb** describes an IN transfer (device-to-host), otherwise 0.

int **usb_urb_dir_out**(struct urb * urb)
check if an URB describes an OUT transfer

Parameters

struct urb * urb URB to be checked

Return

1 if **urb** describes an OUT transfer (host-to-device), otherwise 0.

struct **usb_sg_request**
support for scatter/gather I/O

Definition

```
struct usb_sg_request {
  int status;
  size_t bytes;
};
```

Members

status zero indicates success, else negative errno

bytes counts bytes transferred.

Description

These requests are initialized using `usb_sg_init()`, and then are used as request handles passed to `usb_sg_wait()` or `usb_sg_cancel()`. Most members of the request object aren't for driver access.

The status and bytecount values are valid only after `usb_sg_wait()` returns. If the status is zero, then the bytecount matches the total from the request.

After an error completion, drivers may need to clear a halt condition on the endpoint.

20.1.5 USB Core APIs

There are two basic I/O models in the USB API. The most elemental one is asynchronous: drivers submit requests in the form of an URB, and the URB's completion callback handles the next step. All USB transfer types support that model, although there are special cases for control URBs (which always have setup and status stages, but may not have a data stage) and isochronous URBs (which allow large packets and include per-packet fault reports). Built on top of that is synchronous API support, where a driver calls a routine that allocates one or more URBs, submits them, and waits until they complete. There are synchronous wrappers for single-buffer control and bulk transfers (which are awkward to use in some driver disconnect scenarios), and for scatterlist based streaming i/o (bulk or interrupt).

USB drivers need to provide buffers that can be used for DMA, although they don't necessarily need to provide the DMA mapping themselves. There are APIs to

use used when allocating DMA buffers, which can prevent use of bounce buffers on some systems. In some cases, drivers may be able to rely on 64bit DMA to eliminate another kind of bounce buffer.

void **usb_init_urb**(struct urb * urb)
initializes a urb so that it can be used by a USB driver

Parameters

struct urb * urb pointer to the urb to initialize

Description

Initializes a urb so that the USB subsystem can use it properly.

If a urb is created with a call to `usb_alloc_urb()` it is not necessary to call this function. Only use this if you allocate the space for a struct urb on your own. If you call this function, be careful when freeing the memory for your urb that it is no longer in use by the USB core.

Only use this function if you _really_ understand what you are doing.

struct urb * **usb_alloc_urb**(int iso_packets, gfp_t mem_flags)
creates a new urb for a USB driver to use

Parameters

int iso_packets number of iso packets for this urb

gfp_t mem_flags the type of memory to allocate, see kmalloc() for a list of valid options for this.

Description

Creates an urb for the USB driver to use, initializes a few internal structures, increments the usage counter, and returns a pointer to it.

If the driver want to use this urb for interrupt, control, or bulk endpoints, pass ‘0’ as the number of iso packets.

The driver must call `usb_free_urb()` when it is finished with the urb.

Return

A pointer to the new urb, or `NULL` if no memory is available.

void **usb_free_urb**(struct urb * urb)
frees the memory used by a urb when all users of it are finished

Parameters

struct urb * urb pointer to the urb to free, may be NULL

Description

Must be called when a user of a urb is finished with it. When the last user of the urb calls this function, the memory of the urb is freed.

Note

The transfer buffer associated with the urb is not freed unless the URB_FREE_BUFFER transfer flag is set.

struct urb * **usb_get_urb**(struct urb * urb)
increments the reference count of the urb

Parameters

struct urb * urb pointer to the urb to modify, may be NULL

Description

This must be called whenever a urb is transferred from a device driver to a host controller driver. This allows proper reference counting to happen for urbs.

Return

A pointer to the urb with the incremented reference counter.

void **usb_anchor_urb**(struct urb * urb, struct usb_anchor * anchor)
anchors an URB while it is processed

Parameters

struct urb * urb pointer to the urb to anchor

struct usb_anchor * anchor pointer to the anchor

Description

This can be called to have access to URBs which are to be executed without bothering to track them

void **usb_unanchor_urb**(struct urb * urb)
unanchors an URB

Parameters

struct urb * urb pointer to the urb to anchor

Description

Call this to stop the system keeping track of this URB

int **usb_urb_ep_type_check**(const struct urb * urb)
sanity check of endpoint in the given urb

Parameters

const struct urb * urb urb to be checked

Description

This performs a light-weight sanity check for the endpoint in the given urb. It returns 0 if the urb contains a valid endpoint, otherwise a negative error code.

int **usb_submit_urb**(struct urb * urb, gfp_t mem_flags)
issue an asynchronous transfer request for an endpoint

Parameters

struct urb * urb pointer to the urb describing the request

gfp_t mem_flags the type of memory to allocate, see kmalloc() for a list of valid options for this.

Description

This submits a transfer request, and transfers control of the URB describing that request to the USB subsystem. Request completion will be indicated later, asynchronously, by calling the completion handler. The three types of completion are success, error, and unlink (a software-induced fault, also called "request cancellation").

URBs may be submitted in interrupt context.

The caller must have correctly initialized the URB before submitting it. Functions such as `usb_fill_bulk_urb()` and `usb_fill_control_urb()` are available to ensure that most fields are correctly initialized, for the particular kind of transfer, although they will not initialize any transfer flags.

If the submission is successful, the complete() callback from the URB will be called exactly once, when the USB core and Host Controller Driver (HCD) are finished with the URB. When the completion function is called, control of the URB is returned to the device driver which issued the request. The completion handler may then immediately free or reuse that URB.

With few exceptions, USB device drivers should never access URB fields provided by usbcore or the HCD until its complete() is called. The exceptions relate to periodic transfer scheduling. For both interrupt and isochronous urbs, as part of successful URB submission urb->interval is modified to reflect the actual transfer period used (normally some power of two units). And for isochronous urbs, urb->start_frame is modified to reflect when the URB's transfers were scheduled to start.

Not all isochronous transfer scheduling policies will work, but most host controller drivers should easily handle ISO queues going from now until 10-200 msec into the future. Drivers should try to keep at least one or two msec of data in the queue; many controllers require that new transfers start at least 1 msec in the future when they are added. If the driver is unable to keep up and the queue empties out, the behavior for new submissions is governed by the URB_ISO_ASAP flag. If the flag is set, or if the queue is idle, then the URB is always assigned to the first available (and not yet expired) slot in the endpoint's schedule. If the flag is not set and the queue is active then the URB is always assigned to the next slot in the schedule following the end of the endpoint's previous URB, even if that slot is in the past. When a packet is assigned in this way to a slot that has already expired, the packet is not transmitted and the corresponding usb_iso_packet_descriptor's status field will return -EXDEV. If this would happen to all the packets in the URB, submission fails with a -EXDEV error code.

For control endpoints, the synchronous `usb_control_msg()` call is often used (in non-interrupt context) instead of this call. That is often used through convenience wrappers, for the requests that are standardized in the USB 2.0 specification. For bulk endpoints, a synchronous `usb_bulk_msg()` call is available.

Request Queuing:

URBs may be submitted to endpoints before previous ones complete, to minimize the impact of interrupt latencies and system overhead on data throughput. With that queuing policy, an endpoint's queue would never be empty. This is required for continuous isochronous data streams, and may also be required for some kinds of interrupt transfers. Such queuing also maximizes bandwidth utilization by letting

USB controllers start work on later requests before driver software has finished the completion processing for earlier (successful) requests.

As of Linux 2.6, all USB endpoint transfer queues support depths greater than one. This was previously a HCD-specific behavior, except for ISO transfers. Non-isochronous endpoint queues are inactive during cleanup after faults (transfer errors or cancellation).

Reserved Bandwidth Transfers:

Periodic transfers (interrupt or isochronous) are performed repeatedly, using the interval specified in the urb. Submitting the first urb to the endpoint reserves the bandwidth necessary to make those transfers. If the USB subsystem can't allocate sufficient bandwidth to perform the periodic request, submitting such a periodic request should fail.

For devices under xHCI, the bandwidth is reserved at configuration time, or when the alt setting is selected. If there is not enough bus bandwidth, the configuration/alt setting request will fail. Therefore, submissions to periodic endpoints on devices under xHCI should never fail due to bandwidth constraints.

Device drivers must explicitly request that repetition, by ensuring that some URB is always on the endpoint's queue (except possibly for short periods during completion callbacks). When there is no longer an urb queued, the endpoint's bandwidth reservation is canceled. This means drivers can use their completion handlers to ensure they keep bandwidth they need, by reinitializing and resubmitting the just-completed urb until the driver longer needs that periodic bandwidth.

Memory Flags:

The general rules for how to decide which mem_flags to use are the same as for kmalloc. There are four different possible values; GFP_KERNEL, GFP_NOFS, GFP_NOIO and GFP_ATOMIC.

GFP_NOFS is not ever used, as it has not been implemented yet.

GFP_ATOMIC is used when

(a) you are inside a completion handler, an interrupt, bottom half, tasklet or timer, or

(b) you are holding a spinlock or rwlock (does not apply to semaphores), or

(c) current->state != TASK_RUNNING, this is the case only after you've changed it.

GFP_NOIO is used in the block io path and error handling of storage devices.

All other situations use GFP_KERNEL.

Some more specific rules for mem_flags can be inferred, such as

(1) start_xmit, timeout, and receive methods of network drivers must use GFP_ATOMIC (they are called with a spinlock held);

(2) queuecommand methods of scsi drivers must use GFP_ATOMIC (also called with a spinlock held);

(3) If you use a kernel thread with a network driver you must use GFP_NOIO, unless (b) or (c) apply;

(4) after you have done a down() you can use GFP_KERNEL, unless (b) or (c) apply or your are in a storage driver's block io path;

(5) USB probe and disconnect can use GFP_KERNEL unless (b) or (c) apply; and

(6) changing firmware on a running storage or net device uses GFP_NOIO, unless b) or c) apply

Return

0 on successful submissions. A negative error number otherwise.

int **usb_unlink_urb**(struct urb * urb)
abort/cancel a transfer request for an endpoint

Parameters

struct urb * urb pointer to urb describing a previously submitted request, may be NULL

Description

This routine cancels an in-progress request. URBs complete only once per submission, and may be canceled only once per submission. Successful cancellation means termination of **urb** will be expedited and the completion handler will be called with a status code indicating that the request has been canceled (rather than any other code).

Drivers should not call this routine or related routines, such as `usb_kill_urb()` or `usb_unlink_anchored_urbs()`, after their disconnect method has returned. The disconnect function should synchronize with a driver's I/O routines to insure that all URB-related activity has completed before it returns.

This request is asynchronous, however the HCD might call the ->complete() callback during unlink. Therefore when drivers call `usb_unlink_urb()`, they must not hold any locks that may be taken by the completion function. Success is indicated by returning -EINPROGRESS, at which time the URB will probably not yet have been given back to the device driver. When it is eventually called, the completion function will see **urb->status** == -ECONNRESET. Failure is indicated by `usb_unlink_urb()` returning any other value. Unlinking will fail when **urb** is not currently "linked" (i.e., it was never submitted, or it was unlinked before, or the hardware is already finished with it), even if the completion handler has not yet run.

The URB must not be deallocated while this routine is running. In particular, when a driver calls this routine, it must insure that the completion handler cannot deallocate the URB.

Unlinking and Endpoint Queues:

[The behaviors and guarantees described below do not apply to virtual root hubs but only to endpoint queues for physical USB devices.]

Host Controller Drivers (HCDs) place all the URBs for a particular endpoint in a queue. Normally the queue advances as the controller hardware processes each request. But when an URB terminates with an error its queue generally stops (see below), at least until that URB's completion routine returns. It is guaranteed that a stopped queue will not restart until all its unlinked URBs have been fully

retired, with their completion routines run, even if that's not until some time after the original completion handler returns. The same behavior and guarantee apply when an URB terminates because it was unlinked.

Bulk and interrupt endpoint queues are guaranteed to stop whenever an URB terminates with any sort of error, including -ECONNRESET, -ENOENT, and -EREMOTEIO. Control endpoint queues behave the same way except that they are not guaranteed to stop for -EREMOTEIO errors. Queues for isochronous endpoints are treated differently, because they must advance at fixed rates. Such queues do not stop when an URB encounters an error or is unlinked. An unlinked isochronous URB may leave a gap in the stream of packets; it is undefined whether such gaps can be filled in.

Note that early termination of an URB because a short packet was received will generate a -EREMOTEIO error if and only if the URB_SHORT_NOT_OK flag is set. By setting this flag, USB device drivers can build deep queues for large or complex bulk transfers and clean them up reliably after any sort of aborted transfer by unlinking all pending URBs at the first fault.

When a control URB terminates with an error other than -EREMOTEIO, it is quite likely that the status stage of the transfer will not take place.

Return

-EINPROGRESS on success. See description for other values on failure.

void **usb_kill_urb**(struct urb * urb)
cancel a transfer request and wait for it to finish

Parameters

struct urb * urb pointer to URB describing a previously submitted request, may be NULL

Description

This routine cancels an in-progress request. It is guaranteed that upon return all completion handlers will have finished and the URB will be totally idle and available for reuse. These features make this an ideal way to stop I/O in a disconnect() callback or close() function. If the request has not already finished or been unlinked the completion handler will see urb->status == -ENOENT.

While the routine is running, attempts to resubmit the URB will fail with error -EPERM. Thus even if the URB's completion handler always tries to resubmit, it will not succeed and the URB will become idle.

The URB must not be deallocated while this routine is running. In particular, when a driver calls this routine, it must insure that the completion handler cannot deallocate the URB.

This routine may not be used in an interrupt context (such as a bottom half or a completion handler), or when holding a spinlock, or in other situations where the caller can't schedule().

This routine should not be called by a driver after its disconnect method has returned.

void **usb_poison_urb**(struct urb * urb)
reliably kill a transfer and prevent further use of an URB

Parameters

struct urb * urb pointer to URB describing a previously submitted request, may be NULL

Description

This routine cancels an in-progress request. It is guaranteed that upon return all completion handlers will have finished and the URB will be totally idle and cannot be reused. These features make this an ideal way to stop I/O in a disconnect() callback. If the request has not already finished or been unlinked the completion handler will see urb->status == -ENOENT.

After and while the routine runs, attempts to resubmit the URB will fail with error -EPERM. Thus even if the URB's completion handler always tries to resubmit, it will not succeed and the URB will become idle.

The URB must not be deallocated while this routine is running. In particular, when a driver calls this routine, it must insure that the completion handler cannot deallocate the URB.

This routine may not be used in an interrupt context (such as a bottom half or a completion handler), or when holding a spinlock, or in other situations where the caller can't schedule().

This routine should not be called by a driver after its disconnect method has returned.

void **usb_block_urb**(struct urb * urb)
reliably prevent further use of an URB

Parameters

struct urb * urb pointer to URB to be blocked, may be NULL

Description

After the routine has run, attempts to resubmit the URB will fail with error -EPERM. Thus even if the URB's completion handler always tries to resubmit, it will not succeed and the URB will become idle.

The URB must not be deallocated while this routine is running. In particular, when a driver calls this routine, it must insure that the completion handler cannot deallocate the URB.

void **usb_kill_anchored_urbs**(struct usb_anchor * anchor)
cancel transfer requests en masse

Parameters

struct usb_anchor * anchor anchor the requests are bound to

Description

this allows all outstanding URBs to be killed starting from the back of the queue

This routine should not be called by a driver after its disconnect method has returned.

void **usb_poison_anchored_urbs**(struct usb_anchor * anchor)
cease all traffic from an anchor

Parameters

struct usb_anchor * anchor anchor the requests are bound to

Description

this allows all outstanding URBs to be poisoned starting from the back of the queue. Newly added URBs will also be poisoned

This routine should not be called by a driver after its disconnect method has returned.

void **usb_unpoison_anchored_urbs**(struct usb_anchor * anchor)
let an anchor be used successfully again

Parameters

struct usb_anchor * anchor anchor the requests are bound to

Description

Reverses the effect of usb_poison_anchored_urbs the anchor can be used normally after it returns

void **usb_unlink_anchored_urbs**(struct usb_anchor * anchor)
asynchronously cancel transfer requests en masse

Parameters

struct usb_anchor * anchor anchor the requests are bound to

Description

this allows all outstanding URBs to be unlinked starting from the back of the queue. This function is asynchronous. The unlinking is just triggered. It may happen after this function has returned.

This routine should not be called by a driver after its disconnect method has returned.

void **usb_anchor_suspend_wakeups**(struct usb_anchor * anchor)

Parameters

struct usb_anchor * anchor the anchor you want to suspend wakeups on

Description

Call this to stop the last urb being unanchored from waking up any usb_wait_anchor_empty_timeout waiters. This is used in the hcd urb give- back path to delay waking up until after the completion handler has run.

void **usb_anchor_resume_wakeups**(struct usb_anchor * anchor)

Parameters

struct usb_anchor * anchor the anchor you want to resume wakeups on

Description

Allow usb_wait_anchor_empty_timeout waiters to be woken up again, and wake up any current waiters if the anchor is empty.

int **usb_wait_anchor_empty_timeout**(struct usb_anchor * anchor, unsigned int timeout)
wait for an anchor to be unused

Parameters

struct usb_anchor * anchor the anchor you want to become unused

unsigned int timeout how long you are willing to wait in milliseconds

Description

Call this is you want to be sure all an anchor's URBs have finished

Return

Non-zero if the anchor became unused. Zero on timeout.

struct urb * **usb_get_from_anchor**(struct usb_anchor * anchor)
get an anchor's oldest urb

Parameters

struct usb_anchor * anchor the anchor whose urb you want

Description

This will take the oldest urb from an anchor, unanchor and return it

Return

The oldest urb from **anchor**, or `NULL` if **anchor** has no urbs associated with it.

void **usb_scuttle_anchored_urbs**(struct usb_anchor * anchor)
unanchor all an anchor's urbs

Parameters

struct usb_anchor * anchor the anchor whose urbs you want to unanchor

Description

use this to get rid of all an anchor's urbs

int **usb_anchor_empty**(struct usb_anchor * anchor)
is an anchor empty

Parameters

struct usb_anchor * anchor the anchor you want to query

Return

1 if the anchor has no urbs associated with it.

int **usb_control_msg**(struct usb_device * dev, unsigned int pipe, __u8 request, __u8 requesttype, __u16 value, __u16 index, void * data, __u16 size, int timeout)
Builds a control urb, sends it off and waits for completion

Parameters

struct usb_device * dev pointer to the usb device to send the message to

unsigned int pipe endpoint "pipe" to send the message to

__u8 request USB message request value

__u8 requesttype USB message request type value

__u16 value USB message value

__u16 index USB message index value

void * data pointer to the data to send

__u16 size length in bytes of the data to send

int timeout time in msecs to wait for the message to complete before timing out (if 0 the wait is forever)

Context

!in_interrupt ()

Description

This function sends a simple control message to a specified endpoint and waits for the message to complete, or timeout.

Don't use this function from within an interrupt context. If you need an asynchronous message, or need to send a message from within interrupt context, use `usb_submit_urb()`. If a thread in your driver uses this call, make sure your disconnect() method can wait for it to complete. Since you don't have a handle on the URB used, you can't cancel the request.

Return

If successful, the number of bytes transferred. Otherwise, a negative error number.

int **usb_interrupt_msg**(struct usb_device * usb_dev, unsigned int pipe, void * data, int len, int * actual_length, int timeout)

Builds an interrupt urb, sends it off and waits for completion

Parameters

struct usb_device * usb_dev pointer to the usb device to send the message to

unsigned int pipe endpoint "pipe" to send the message to

void * data pointer to the data to send

int len length in bytes of the data to send

int * actual_length pointer to a location to put the actual length transferred in bytes

int timeout time in msecs to wait for the message to complete before timing out (if 0 the wait is forever)

Context

!in_interrupt ()

Description

This function sends a simple interrupt message to a specified endpoint and waits for the message to complete, or timeout.

Don't use this function from within an interrupt context. If you need an asynchronous message, or need to send a message from within interrupt context, use `usb_submit_urb()` If a thread in your driver uses this call, make sure your disconnect() method can wait for it to complete. Since you don't have a handle on the URB used, you can't cancel the request.

Return

If successful, 0. Otherwise a negative error number. The number of actual bytes transferred will be stored in the **actual_length** parameter.

int **usb_bulk_msg**(struct usb_device * usb_dev, unsigned int pipe, void * data, int len, int * actual_length, int timeout)
Builds a bulk urb, sends it off and waits for completion

Parameters

struct usb_device * usb_dev pointer to the usb device to send the message to

unsigned int pipe endpoint "pipe" to send the message to

void * data pointer to the data to send

int len length in bytes of the data to send

int * actual_length pointer to a location to put the actual length transferred in bytes

int timeout time in msecs to wait for the message to complete before timing out (if 0 the wait is forever)

Context

!in_interrupt ()

Description

This function sends a simple bulk message to a specified endpoint and waits for the message to complete, or timeout.

Don't use this function from within an interrupt context. If you need an asynchronous message, or need to send a message from within interrupt context, use `usb_submit_urb()` If a thread in your driver uses this call, make sure your disconnect() method can wait for it to complete. Since you don't have a handle on the URB used, you can't cancel the request.

Because there is no `usb_interrupt_msg()` and no USBDEVFS_INTERRUPT ioctl, users are forced to abuse this routine by using it to submit URBs for interrupt endpoints. We will take the liberty of creating an interrupt URB (with the default interval) if the target is an interrupt endpoint.

Return

If successful, 0. Otherwise a negative error number. The number of actual bytes transferred will be stored in the **actual_length** parameter.

int **usb_sg_init**(struct usb_sg_request * io, struct usb_device * dev, unsigned pipe, unsigned period, struct scatterlist * sg, int nents, size_t length, gfp_t mem_flags)
initializes scatterlist-based bulk/interrupt I/O request

Parameters

struct usb_sg_request * io request block being initialized. until `usb_sg_wait()` returns, treat this as a pointer to an opaque block of memory,

struct usb_device * dev the usb device that will send or receive the data

unsigned pipe endpoint "pipe" used to transfer the data

unsigned period polling rate for interrupt endpoints, in frames or (for high speed endpoints) microframes; ignored for bulk

struct scatterlist * sg scatterlist entries

int nents how many entries in the scatterlist

size_t length how many bytes to send from the scatterlist, or zero to send every byte identified in the list.

gfp_t mem_flags SLAB_* flags affecting memory allocations in this call

Description

This initializes a scatter/gather request, allocating resources such as I/O mappings and urb memory (except maybe memory used by USB controller drivers).

The request must be issued using `usb_sg_wait()`, which waits for the I/O to complete (or to be canceled) and then cleans up all resources allocated by `usb_sg_init()`.

The request may be canceled with `usb_sg_cancel()`, either before or after `usb_sg_wait()` is called.

Return

Zero for success, else a negative errno value.

void **usb_sg_wait**(struct usb_sg_request * io)
synchronously execute scatter/gather request

Parameters

struct usb_sg_request * io request block handle, as initialized with `usb_sg_init()`. some fields become accessible when this call returns.

Context

!in_interrupt ()

Description

This function blocks until the specified I/O operation completes. It leverages the grouping of the related I/O requests to get good transfer rates, by queueing the requests. At higher speeds, such queuing can significantly improve USB throughput.

There are three kinds of completion for this function.

(1) success, where io->status is zero. The number of io->bytes transferred is as requested.

(2) error, where io->status is a negative errno value. The number of io->bytes transferred before the error is usually less than requested, and can be nonzero.

(3) cancellation, a type of error with status -ECONNRESET that is initiated by `usb_sg_cancel()`.

When this function returns, all memory allocated through `usb_sg_init()` or this call will have been freed. The request block parameter may still be passed to `usb_sg_cancel()`, or it may be freed. It could also be reinitialized and then reused.

Data Transfer Rates:

Bulk transfers are valid for full or high speed endpoints. The best full speed data rate is 19 packets of 64 bytes each per frame, or 1216 bytes per millisecond. The best high speed data rate is 13 packets of 512 bytes each per microframe, or 52 KBytes per millisecond.

The reason to use interrupt transfers through this API would most likely be to reserve high speed bandwidth, where up to 24 KBytes per millisecond could be transferred. That capability is less useful for low or full speed interrupt endpoints, which allow at most one packet per millisecond, of at most 8 or 64 bytes (respectively).

It is not necessary to call this function to reserve bandwidth for devices under an xHCI host controller, as the bandwidth is reserved when the configuration or interface alt setting is selected.

void **usb_sg_cancel**(struct usb_sg_request * io)
stop scatter/gather i/o issued by `usb_sg_wait()`

Parameters

struct usb_sg_request * io request block, initialized with `usb_sg_init()`

Description

This stops a request after it has been started by `usb_sg_wait()`. It can also prevents one initialized by `usb_sg_init()` from starting, so that call just frees resources allocated to the request.

int **usb_get_descriptor**(struct usb_device * dev, unsigned char type, unsigned char index, void * buf, int size)
issues a generic GET_DESCRIPTOR request

Parameters

struct usb_device * dev the device whose descriptor is being retrieved

unsigned char type the descriptor type (USB_DT_*)

unsigned char index the number of the descriptor

void * buf where to put the descriptor

int size how big is “buf” ?

Context

!in_interrupt ()

Description

Gets a USB descriptor. Convenience functions exist to simplify getting some types of descriptors. Use usb_get_string() or `usb_string()` for USB_DT_STRING. Device (USB_DT_DEVICE) and configuration descriptors (USB_DT_CONFIG) are part of the device structure. In addition to a number of USB-standard descriptors, some devices also use class-specific or vendor-specific descriptors.

This call is synchronous, and may not be used in an interrupt context.

Return

The number of bytes received on success, or else the status code returned by the underlying `usb_control_msg()` call.

int **usb_string**(struct usb_device * dev, int index, char * buf, size_t size)
returns UTF-8 version of a string descriptor

Parameters

struct usb_device * dev the device whose string descriptor is being retrieved

int index the number of the descriptor

char * buf where to put the string

size_t size how big is "buf"?

Context

!in_interrupt ()

Description

This converts the UTF-16LE encoded strings returned by devices, from usb_get_string_descriptor(), to null-terminated UTF-8 encoded ones that are more usable in most kernel contexts. Note that this function chooses strings in the first language supported by the device.

This call is synchronous, and may not be used in an interrupt context.

Return

length of the string (>= 0) or usb_control_msg status (< 0).

int **usb_get_status**(struct usb_device * dev, int recip, int type, int target, void * data)
issues a GET_STATUS call

Parameters

struct usb_device * dev the device whose status is being checked

int recip USB_RECIP_*; for device, interface, or endpoint

int type USB_STATUS_TYPE_*; for standard or PTM status types

int target zero (for device), else interface or endpoint number

void * data pointer to two bytes of bitmap data

Context

!in_interrupt ()

Description

Returns device, interface, or endpoint status. Normally only of interest to see if the device is self powered, or has enabled the remote wakeup facility; or whether a bulk or interrupt endpoint is halted (“stalled”).

Bits in these status bitmaps are set using the SET_FEATURE request, and cleared using the CLEAR_FEATURE request. The `usb_clear_halt()` function should be used to clear halt (“stall”) status.

This call is synchronous, and may not be used in an interrupt context.

Returns 0 and the status value in ***data** (in host byte order) on success, or else the status code from the underlying `usb_control_msg()` call.

int **usb_clear_halt**(struct usb_device * dev, int pipe)
tells device to clear endpoint halt/stall condition

Parameters

struct usb_device * dev device whose endpoint is halted

int pipe endpoint “pipe” being cleared

Context

!in_interrupt ()

Description

This is used to clear halt conditions for bulk and interrupt endpoints, as reported by URB completion status. Endpoints that are halted are sometimes referred to as being “stalled”. Such endpoints are unable to transmit or receive data until the halt status is cleared. Any URBs queued for such an endpoint should normally be unlinked by the driver before clearing the halt condition, as described in sections 5.7.5 and 5.8.5 of the USB 2.0 spec.

Note that control and isochronous endpoints don’t halt, although control endpoints report “protocol stall” (for unsupported requests) using the same status code used to report a true stall.

This call is synchronous, and may not be used in an interrupt context.

Return

Zero on success, or else the status code returned by the underlying `usb_control_msg()` call.

void **usb_reset_endpoint**(struct usb_device * dev, unsigned int epaddr)
Reset an endpoint’s state.

Parameters

struct usb_device * dev the device whose endpoint is to be reset

unsigned int epaddr the endpoint’s address. Endpoint number for output, endpoint number + USB_DIR_IN for input

Description

Resets any host-side endpoint state such as the toggle bit, sequence number or current window.

int **usb_set_interface**(struct usb_device * dev, int interface, int alternate)
Makes a particular alternate setting be current

Parameters

struct usb_device * dev the device whose interface is being updated

int interface the interface being updated

int alternate the setting being chosen.

Context

!in_interrupt ()

Description

This is used to enable data transfers on interfaces that may not be enabled by default. Not all devices support such configurability. Only the driver bound to an interface may change its setting.

Within any given configuration, each interface may have several alternative settings. These are often used to control levels of bandwidth consumption. For example, the default setting for a high speed interrupt endpoint may not send more than 64 bytes per microframe, while interrupt transfers of up to 3KBytes per microframe are legal. Also, isochronous endpoints may never be part of an interface' s default setting. To access such bandwidth, alternate interface settings must be made current.

Note that in the Linux USB subsystem, bandwidth associated with an endpoint in a given alternate setting is not reserved until an URB is submitted that needs that bandwidth. Some other operating systems allocate bandwidth early, when a configuration is chosen.

xHCI reserves bandwidth and configures the alternate setting in usb_hcd_alloc_bandwidth(). If it fails the original interface altsetting may be disabled. Drivers cannot rely on any particular alternate setting being in effect after a failure.

This call is synchronous, and may not be used in an interrupt context. Also, drivers must not change altsettings while urbs are scheduled for endpoints in that interface; all such urbs must first be completed (perhaps forced by unlinking).

Return

Zero on success, or else the status code returned by the underlying `usb_control_msg()` call.

int **usb_reset_configuration**(struct usb_device * dev)
lightweight device reset

Parameters

struct usb_device * dev the device whose configuration is being reset

Description

This issues a standard SET_CONFIGURATION request to the device using the current configuration. The effect is to reset most USB-related state in the device, including interface altsettings (reset to zero), endpoint halts (cleared), and endpoint

state (only for bulk and interrupt endpoints). Other usbcore state is unchanged, including bindings of usb device drivers to interfaces.

Because this affects multiple interfaces, avoid using this with composite (multi-interface) devices. Instead, the driver for each interface may use `usb_set_interface()` on the interfaces it claims. Be careful though; some devices don't support the SET_INTERFACE request, and others won't reset all the interface state (notably endpoint state). Resetting the whole configuration would affect other drivers' interfaces.

The caller must own the device lock.

Return

Zero on success, else a negative error code.

int **usb_driver_set_configuration**(struct usb_device * udev, int config)
Provide a way for drivers to change device configurations

Parameters

struct usb_device * udev the device whose configuration is being updated

int config the configuration being chosen.

Context

In process context, must be able to sleep

Description

Device interface drivers are not allowed to change device configurations. This is because changing configurations will destroy the interface the driver is bound to and create new ones; it would be like a floppy-disk driver telling the computer to replace the floppy-disk drive with a tape drive!

Still, in certain specialized circumstances the need may arise. This routine gets around the normal restrictions by using a work thread to submit the change-config request.

Return

0 if the request was successfully queued, error code otherwise. The caller has no way to know whether the queued request will eventually succeed.

int **cdc_parse_cdc_header**(struct usb_cdc_parsed_header * hdr, struct usb_interface * intf, u8 * buffer, int buflen)
parse the extra headers present in CDC devices

Parameters

struct usb_cdc_parsed_header * hdr the place to put the results of the parsing

struct usb_interface * intf the interface for which parsing is requested

u8 * buffer pointer to the extra headers to be parsed

int buflen length of the extra headers

Description

This evaluates the extra headers present in CDC devices which bind the interfaces for data and control and provide details about the capabilities of the device.

Return

number of descriptors parsed or -EINVAL if the header is contradictory beyond salvage

int **usb_register_dev**(struct usb_interface * intf, struct usb_class_driver * class_driver)
register a USB device, and ask for a minor number

Parameters

struct usb_interface * intf pointer to the usb_interface that is being registered

struct usb_class_driver * class_driver pointer to the usb_class_driver for this device

Description

This should be called by all USB drivers that use the USB major number. If CONFIG_USB_DYNAMIC_MINORS is enabled, the minor number will be dynamically allocated out of the list of available ones. If it is not enabled, the minor number will be based on the next available free minor, starting at the class_driver->minor_base.

This function also creates a usb class device in the sysfs tree.

`usb_deregister_dev()` must be called when the driver is done with the minor numbers given out by this function.

Return

-EINVAL if something bad happens with trying to register a device, and 0 on success.

void **usb_deregister_dev**(struct usb_interface * intf, struct usb_class_driver * class_driver)
deregister a USB device's dynamic minor.

Parameters

struct usb_interface * intf pointer to the usb_interface that is being deregistered

struct usb_class_driver * class_driver pointer to the usb_class_driver for this device

Description

Used in conjunction with `usb_register_dev()`. This function is called when the USB driver is finished with the minor numbers gotten from a call to `usb_register_dev()` (usually when the device is disconnected from the system.)

This function also removes the usb class device from the sysfs tree.

This should be called by all drivers that use the USB major number.

int **usb_driver_claim_interface**(struct usb_driver * driver, struct usb_interface * iface, void * priv)
bind a driver to an interface

Parameters

struct usb_driver * driver the driver to be bound

struct usb_interface * iface the interface to which it will be bound; must be in the usb device's active configuration

void * priv driver data associated with that interface

Description

This is used by usb device drivers that need to claim more than one interface on a device when probing (audio and acm are current examples). No device driver should directly modify internal usb_interface or usb_device structure members.

Few drivers should need to use this routine, since the most natural way to bind to an interface is to return the private data from the driver's probe() method.

Callers must own the device lock, so driver probe() entries don't need extra locking, but other call contexts may need to explicitly claim that lock.

Return

0 on success.

void **usb_driver_release_interface**(struct usb_driver * driver, struct usb_interface * iface)
unbind a driver from an interface

Parameters

struct usb_driver * driver the driver to be unbound

struct usb_interface * iface the interface from which it will be unbound

Description

This can be used by drivers to release an interface without waiting for their disconnect() methods to be called. In typical cases this also causes the driver disconnect() method to be called.

This call is synchronous, and may not be used in an interrupt context. Callers must own the device lock, so driver disconnect() entries don't need extra locking, but other call contexts may need to explicitly claim that lock.

const struct usb_device_id * **usb_match_id**(struct usb_interface * interface, const struct usb_device_id * id)
find first usb_device_id matching device or interface

Parameters

struct usb_interface * interface the interface of interest

const struct usb_device_id * id array of usb_device_id structures, terminated by zero entry

Description

usb_match_id searches an array of usb_device_id's and returns the first one matching the device or interface, or null. This is used when binding (or rebinding) a driver to an interface. Most USB device drivers will use this indirectly, through the usb core, but some layered driver frameworks use it directly. These device tables are exported with MODULE_DEVICE_TABLE, through modutils, to support the driver loading functionality of USB hotplugging.

What Matches:

The “match_flags” element in a usb_device_id controls which members are used. If the corresponding bit is set, the value in the device_id must match its corresponding member in the device or interface descriptor, or else the device_id does not match.

“driver_info” is normally used only by device drivers, but you can create a wildcard “matches anything” usb_device_id as a driver’s “modules.usbmap” entry if you provide an id with only a nonzero “driver_info” field. If you do this, the USB device driver’s probe() routine should use additional intelligence to decide whether to bind to the specified interface.

What Makes Good usb_device_id Tables:

The match algorithm is very simple, so that intelligence in driver selection must come from smart driver id records. Unless you have good reasons to use another selection policy, provide match elements only in related groups, and order match specifiers from specific to general. Use the macros provided for that purpose if you can.

The most specific match specifiers use device descriptor data. These are commonly used with product-specific matches; the USB_DEVICE macro lets you provide vendor and product IDs, and you can also match against ranges of product revisions. These are widely used for devices with application or vendor specific bDeviceClass values.

Matches based on device class/subclass/protocol specifications are slightly more general; use the USB_DEVICE_INFO macro, or its siblings. These are used with single-function devices where bDeviceClass doesn’t specify that each interface has its own class.

Matches based on interface class/subclass/protocol are the most general; they let drivers bind to any interface on a multiple-function device. Use the USB_INTERFACE_INFO macro, or its siblings, to match class-per-interface style devices (as recorded in bInterfaceClass).

Note that an entry created by USB_INTERFACE_INFO won’t match any interface if the device class is set to Vendor-Specific. This is deliberate; according to the USB spec the meanings of the interface class/subclass/protocol for these devices are also vendor-specific, and hence matching against a standard product class wouldn’t work anyway. If you really want to use an interface-based match for such a device, create a match record that also specifies the vendor ID. (Unforunately there isn’t a standard macro for creating records like this.)

Within those groups, remember that not all combinations are meaningful. For example, don’t give a product version range without vendor and product IDs; or specify a protocol without its associated class and subclass.

Return

The first matching usb_device_id, or `NULL`.

int **usb_register_device_driver**(struct usb_device_driver * new_udriver,
struct module * owner)
register a USB device (not interface) driver

Parameters

struct usb_device_driver * new_udriver USB operations for the device driver

struct module * owner module owner of this driver.

Description

Registers a USB device driver with the USB core. The list of unattached devices will be rescanned whenever a new driver is added, allowing the new driver to attach to any recognized devices.

Return

A negative error code on failure and 0 on success.

void **usb_deregister_device_driver**(struct usb_device_driver * udriver)
unregister a USB device (not interface) driver

Parameters

struct usb_device_driver * udriver USB operations of the device driver to unregister

Context

must be able to sleep

Description

Unlinks the specified driver from the internal USB driver list.

int **usb_register_driver**(struct usb_driver * new_driver, struct module * owner, const char * mod_name)
register a USB interface driver

Parameters

struct usb_driver * new_driver USB operations for the interface driver

struct module * owner module owner of this driver.

const char * mod_name module name string

Description

Registers a USB interface driver with the USB core. The list of unattached interfaces will be rescanned whenever a new driver is added, allowing the new driver to attach to any recognized interfaces.

Return

A negative error code on failure and 0 on success.

NOTE

if you want your driver to use the USB major number, you must call `usb_register_dev()` to enable that functionality. This function no longer takes care of that.

void **usb_deregister**(struct usb_driver * driver)
unregister a USB interface driver

Parameters

struct usb_driver * driver USB operations of the interface driver to unregister

Context

must be able to sleep

Description

Unlinks the specified driver from the internal USB driver list.

NOTE

If you called `usb_register_dev()`, you still need to call `usb_deregister_dev()` to clean up your driver's allocated minor numbers, this * call will no longer do it for you.

void **usb_enable_autosuspend**(struct usb_device * udev)
allow a USB device to be autosuspended

Parameters

struct usb_device * udev the USB device which may be autosuspended

Description

This routine allows **udev** to be autosuspended. An autosuspend won't take place until the autosuspend_delay has elapsed and all the other necessary conditions are satisfied.

The caller must hold **udev**'s device lock.

void **usb_disable_autosuspend**(struct usb_device * udev)
prevent a USB device from being autosuspended

Parameters

struct usb_device * udev the USB device which may not be autosuspended

Description

This routine prevents **udev** from being autosuspended and wakes it up if it is already autosuspended.

The caller must hold **udev**'s device lock.

void **usb_autopm_put_interface**(struct usb_interface * intf)
decrement a USB interface's PM-usage counter

Parameters

struct usb_interface * intf the usb_interface whose counter should be decremented

Description

This routine should be called by an interface driver when it is finished using **intf** and wants to allow it to autosuspend. A typical example would be a character-device driver when its device file is closed.

The routine decrements **intf**'s usage counter. When the counter reaches 0, a delayed autosuspend request for **intf**'s device is attempted. The attempt may fail (see autosuspend_check()).

This routine can run only in process context.

void **usb_autopm_put_interface_async**(struct usb_interface * intf)
decrement a USB interface's PM-usage counter

Parameters

struct usb_interface * intf the usb_interface whose counter should be decremented

Description

This routine does much the same thing as `usb_autopm_put_interface()`: It decrements **intf**'s usage counter and schedules a delayed autosuspend request if the counter is <= 0. The difference is that it does not perform any synchronization; callers should hold a private lock and handle all synchronization issues themselves.

Typically a driver would call this routine during an URB's completion handler, if no more URBs were pending.

This routine can run in atomic context.

void **usb_autopm_put_interface_no_suspend**(struct usb_interface * intf)
decrement a USB interface's PM-usage counter

Parameters

struct usb_interface * intf the usb_interface whose counter should be decremented

Description

This routine decrements **intf**'s usage counter but does not carry out an autosuspend.

This routine can run in atomic context.

int **usb_autopm_get_interface**(struct usb_interface * intf)
increment a USB interface's PM-usage counter

Parameters

struct usb_interface * intf the usb_interface whose counter should be incremented

Description

This routine should be called by an interface driver when it wants to use **intf** and needs to guarantee that it is not suspended. In addition, the routine prevents **intf** from being autosuspended subsequently. (Note that this will not prevent suspend events originating in the PM core.) This prevention will persist until `usb_autopm_put_interface()` is called or **intf** is unbound. A typical example would be a character-device driver when its device file is opened.

intf's usage counter is incremented to prevent subsequent autosuspends. However if the autoresume fails then the counter is re-decremented.

This routine can run only in process context.

Return

0 on success.

int **usb_autopm_get_interface_async**(struct usb_interface * intf)
increment a USB interface's PM-usage counter

Parameters

struct usb_interface * intf the usb_interface whose counter should be incremented

Description

This routine does much the same thing as `usb_autopm_get_interface()`: It increments **intf**'s usage counter and queues an autoresume request if the device is suspended. The differences are that it does not perform any synchronization (callers should hold a private lock and handle all synchronization issues themselves), and it does not autoresume the device directly (it only queues a request). After a successful call, the device may not yet be resumed.

This routine can run in atomic context.

Return

0 on success. A negative error code otherwise.

void **usb_autopm_get_interface_no_resume**(struct usb_interface * intf)
increment a USB interface's PM-usage counter

Parameters

struct usb_interface * intf the usb_interface whose counter should be incremented

Description

This routine increments **intf**'s usage counter but does not carry out an autoresume.

This routine can run in atomic context.

int **usb_find_common_endpoints**(struct usb_host_interface * alt, struct usb_endpoint_descriptor ** bulk_in, struct usb_endpoint_descriptor ** bulk_out, struct usb_endpoint_descriptor ** int_in, struct usb_endpoint_descriptor ** int_out)

- look up common endpoint descriptors

Parameters

struct usb_host_interface * alt alternate setting to search

struct usb_endpoint_descriptor ** bulk_in pointer to descriptor pointer, or NULL

struct usb_endpoint_descriptor ** bulk_out pointer to descriptor pointer, or NULL

struct usb_endpoint_descriptor ** int_in pointer to descriptor pointer, or NULL

struct usb_endpoint_descriptor ** int_out pointer to descriptor pointer, or NULL

Description

Search the alternate setting's endpoint descriptors for the first bulk-in, bulk-out, interrupt-in and interrupt-out endpoints and return them in the provided pointers (unless they are NULL).

If a requested endpoint is not found, the corresponding pointer is set to NULL.

Return

Zero if all requested descriptors were found, or -ENXIO otherwise.

int **usb_find_common_endpoints_reverse**(struct usb_host_interface * alt, struct usb_endpoint_descriptor ** bulk_in, struct usb_endpoint_descriptor ** bulk_out, struct usb_endpoint_descriptor ** int_in, struct usb_endpoint_descriptor ** int_out)

- look up common endpoint descriptors

Parameters

struct usb_host_interface * alt alternate setting to search

struct usb_endpoint_descriptor ** bulk_in pointer to descriptor pointer, or NULL

struct usb_endpoint_descriptor ** bulk_out pointer to descriptor pointer, or NULL

struct usb_endpoint_descriptor ** int_in pointer to descriptor pointer, or NULL

struct usb_endpoint_descriptor ** int_out pointer to descriptor pointer, or NULL

Description

Search the alternate setting's endpoint descriptors for the last bulk-in, bulk-out, interrupt-in and interrupt-out endpoints and return them in the provided pointers (unless they are NULL).

If a requested endpoint is not found, the corresponding pointer is set to NULL.

Return

Zero if all requested descriptors were found, or -ENXIO otherwise.

struct usb_host_interface * **usb_find_alt_setting**(struct usb_host_config * config, unsigned int iface_num, unsigned int alt_num)

Given a configuration, find the alternate setting for the given interface.

Parameters

struct usb_host_config * config the configuration to search (not necessarily the current config).

unsigned int iface_num interface number to search in

unsigned int alt_num alternate interface setting number to search for.

Description

Search the configuration's interface cache for the given alt setting.

Return

The alternate setting, if found. NULL otherwise.

struct usb_interface * **usb_ifnum_to_if**(const struct usb_device * dev, unsigned ifnum)
get the interface object with a given interface number

Parameters

const struct usb_device * dev the device whose current configuration is considered

unsigned ifnum the desired interface

Description

This walks the device descriptor for the currently active configuration to find the interface object with the particular interface number.

Note that configuration descriptors are not required to assign interface numbers sequentially, so that it would be incorrect to assume that the first interface in that descriptor corresponds to interface zero. This routine helps device drivers avoid such mistakes. However, you should make sure that you do the right thing with any alternate settings available for this interfaces.

Don't call this function unless you are bound to one of the interfaces on this device or you have locked the device!

Return

A pointer to the interface that has **ifnum** as interface number, if found. NULL otherwise.

struct usb_host_interface * **usb_altnum_to_altsetting**(const struct usb_interface * intf, unsigned int altnum)
get the altsetting structure with a given alternate setting number.

Parameters

const struct usb_interface * intf the interface containing the altsetting in question

unsigned int altnum the desired alternate setting number

Description

This searches the altsetting array of the specified interface for an entry with the correct bAlternateSetting value.

Note that altsettings need not be stored sequentially by number, so it would be incorrect to assume that the first altsetting entry in the array corresponds to altsetting zero. This routine helps device drivers avoid such mistakes.

Don't call this function unless you are bound to the intf interface or you have locked the device!

Return

A pointer to the entry of the altsetting array of **intf** that has **altnum** as the alternate setting number. `NULL` if not found.

struct usb_interface * **usb_find_interface**(struct usb_driver * drv, int minor)
find usb_interface pointer for driver and device

Parameters

struct usb_driver * drv the driver whose current configuration is considered

int minor the minor number of the desired device

Description

This walks the bus device list and returns a pointer to the interface with the matching minor and driver. Note, this only works for devices that share the USB major number.

Return

A pointer to the interface with the matching major and **minor**.

int **usb_for_each_dev**(void * data, int (*fn)(struct usb_device *, void *))
iterate over all USB devices in the system

Parameters

void * data data pointer that will be handed to the callback function

int (*)(struct usb_device *, void *) fn callback function to be called for each USB device

Description

Iterate over all USB devices and call **fn** for each, passing it **data**. If it returns anything other than 0, we break the iteration prematurely and return that value.

struct usb_device * **usb_alloc_dev**(struct usb_device * parent, struct usb_bus * bus, unsigned port1)
usb device constructor (usbcore-internal)

Parameters

struct usb_device * parent hub to which device is connected; null to allocate a root hub

struct usb_bus * bus bus used to access the device

unsigned port1 one-based index of port; ignored for root hubs

Context

!in_interrupt()

Description

Only hub drivers (including virtual root hub drivers for host controllers) should ever call this.

This call may not be used in a non-sleeping context.

Return

On success, a pointer to the allocated usb device. NULL on failure.

struct usb_device * **usb_get_dev**(struct usb_device * dev)
increments the reference count of the usb device structure

Parameters

struct usb_device * dev the device being referenced

Description

Each live reference to a device should be refcounted.

Drivers for USB interfaces should normally record such references in their probe() methods, when they bind to an interface, and release them by calling usb_put_dev(), in their disconnect() methods.

Return

A pointer to the device with the incremented reference counter.

void **usb_put_dev**(struct usb_device * dev)
release a use of the usb device structure

Parameters

struct usb_device * dev device that's been disconnected

Description

Must be called when a user of a device is finished with it. When the last user of the device calls this function, the memory of the device is freed.

struct usb_interface * **usb_get_intf**(struct usb_interface * intf)
increments the reference count of the usb interface structure

Parameters

struct usb_interface * intf the interface being referenced

Description

Each live reference to a interface must be refcounted.

Drivers for USB interfaces should normally record such references in their probe() methods, when they bind to an interface, and release them by calling usb_put_intf(), in their disconnect() methods.

Return

A pointer to the interface with the incremented reference counter.

void **usb_put_intf**(struct usb_interface * intf)
release a use of the usb interface structure

Parameters

struct usb_interface * intf interface that's been decremented

Description

Must be called when a user of an interface is finished with it. When the last user of the interface calls this function, the memory of the interface is freed.

int **usb_lock_device_for_reset**(struct usb_device * udev, const struct usb_interface * iface)
cautiously acquire the lock for a usb device structure

Parameters

struct usb_device * udev device that's being locked

const struct usb_interface * iface interface bound to the driver making the request (optional)

Description

Attempts to acquire the device lock, but fails if the device is NOTATTACHED or SUSPENDED, or if iface is specified and the interface is neither BINDING nor BOUND. Rather than sleeping to wait for the lock, the routine polls repeatedly. This is to prevent deadlock with disconnect; in some drivers (such as usb-storage) the disconnect() or suspend() method will block waiting for a device reset to complete.

Return

A negative error code for failure, otherwise 0.

int **usb_get_current_frame_number**(struct usb_device * dev)
return current bus frame number

Parameters

struct usb_device * dev the device whose bus is being queried

Return

The current frame number for the USB host controller used with the given USB device. This can be used when scheduling isochronous requests.

Note

Different kinds of host controller have different "scheduling horizons". While one type might support scheduling only 32 frames into the future, others could support scheduling up to 1024 frames into the future.

void * **usb_alloc_coherent**(struct usb_device * dev, size_t size, gfp_t mem_flags, dma_addr_t * dma)
allocate dma-consistent buffer for URB_NO_xxx_DMA_MAP

Parameters

struct usb_device * dev device the buffer will be used with

size_t size requested buffer size

gfp_t mem_flags affect whether allocation may block

dma_addr_t * dma used to return DMA address of buffer

Return

Either null (indicating no buffer could be allocated), or the cpu-space pointer to a buffer that may be used to perform DMA to the specified device. Such cpu-space buffers are returned along with the DMA address (through the pointer provided).

Note

These buffers are used with URB_NO_xxx_DMA_MAP set in urb->transfer_flags to avoid behaviors like using "DMA bounce buffers", or thrashing IOMMU hardware during URB completion/resubmit. The implementation varies between platforms, depending on details of how DMA will work to this device. Using these buffers also eliminates cacheline sharing problems on architectures where CPU caches are not DMA-coherent. On systems without bus-snooping caches, these buffers are uncached.

Description

When the buffer is no longer used, free it with `usb_free_coherent()`.

void **usb_free_coherent**(struct usb_device * dev, size_t size, void * addr, dma_addr_t dma)
free memory allocated with `usb_alloc_coherent()`

Parameters

struct usb_device * dev device the buffer was used with

size_t size requested buffer size

void * addr CPU address of buffer

dma_addr_t dma DMA address of buffer

Description

This reclaims an I/O buffer, letting it be reused. The memory must have been allocated using `usb_alloc_coherent()`, and the parameters must match those provided in that allocation request.

int **usb_hub_clear_tt_buffer**(struct urb * urb)
clear control/bulk TT state in high speed hub

Parameters

struct urb * urb an URB associated with the failed or incomplete split transaction

Description

High speed HCDs use this to tell the hub driver that some split control or bulk transaction failed in a way that requires clearing internal state of a transaction translator. This is normally detected (and reported) from interrupt context.

It may not be possible for that hub to handle additional full (or low) speed transactions until that state is fully cleared out.

Return

0 if successful. A negative error code otherwise.

void **usb_set_device_state**(struct usb_device * udev, enum usb_device_state new_state)
change a device's current state (usbcore, hcds)

Parameters

struct usb_device * udev pointer to device whose state should be changed

enum usb_device_state new_state new state value to be stored

Description

udev->state is _not_ fully protected by the device lock. Although most transitions are made only while holding the lock, the state can can change to USB_STATE_NOTATTACHED at almost any time. This is so that devices can be marked as disconnected as soon as possible, without having to wait for any semaphores to be released. As a result, all changes to any device's state must be protected by the device_state_lock spinlock.

Once a device has been added to the device tree, all changes to its state should be made using this routine. The state should _not_ be set directly.

If udev->state is already USB_STATE_NOTATTACHED then no change is made. Otherwise udev->state is set to new_state, and if new_state is USB_STATE_NOTATTACHED then all of udev's descendants' states are also set to USB_STATE_NOTATTACHED.

void **usb_root_hub_lost_power**(struct usb_device * rhdev)
called by HCD if the root hub lost Vbus power

Parameters

struct usb_device * rhdev struct usb_device for the root hub

Description

The USB host controller driver calls this function when its root hub is resumed and Vbus power has been interrupted or the controller has been reset. The routine marks **rhdev** as having lost power. When the hub driver is resumed it will take notice and carry out power-session recovery for all the "USB-PERSIST"-enabled child devices; the others will be disconnected.

int **usb_reset_device**(struct usb_device * udev)
warn interface drivers and perform a USB port reset

Parameters

struct usb_device * udev device to reset (not in NOTATTACHED state)

Description

Warns all drivers bound to registered interfaces (using their pre_reset method), performs the port reset, and then lets the drivers know that the reset is over (using their post_reset method).

If an interface is currently being probed or disconnected, we assume its driver knows how to handle resets. For all other interfaces, if the driver doesn't have pre_reset and post_reset methods then we attempt to unbind it and rebind afterward.

Return

The same as for usb_reset_and_verify_device().

Note

The caller must own the device lock. For example, it's safe to use this from a driver probe() routine after downloading new firmware. For calls that might not occur during probe(), drivers should lock the device using `usb_lock_device_for_reset()`.

void **usb_queue_reset_device**(struct usb_interface * iface)
Reset a USB device from an atomic context

Parameters

struct usb_interface * iface USB interface belonging to the device to reset

Description

This function can be used to reset a USB device from an atomic context, where `usb_reset_device()` won't work (as it blocks).

Doing a reset via this method is functionally equivalent to calling `usb_reset_device()`, except for the fact that it is delayed to a workqueue. This means that any drivers bound to other interfaces might be unbound, as well as users from usbfs in user space.

Corner cases:

- Scheduling two resets at the same time from two different drivers attached to two different interfaces of the same device is possible; depending on how the driver attached to each interface handles ->pre_reset(), the second reset might happen or not.
- If the reset is delayed so long that the interface is unbound from its driver, the reset will be skipped.
- This function can be called during .probe(). It can also be called during .disconnect(), but doing so is pointless because the reset will not occur. If you really want to reset the device during .disconnect(), call `usb_reset_device()` directly – but watch out for nested unbinding issues!

struct usb_device * **usb_hub_find_child**(struct usb_device * hdev,
int port1)
Get the pointer of child device attached to the port which is specified by **port1**.

Parameters

struct usb_device * hdev USB device belonging to the usb hub

int port1 port num to indicate which port the child device is attached to.

Description

USB drivers call this function to get hub's child device pointer.

Return

`NULL` if input param is invalid and child's usb_device pointer if non-NULL.

20.1.6 Host Controller APIs

These APIs are only for use by host controller drivers, most of which implement standard register interfaces such as XHCI, EHCI, OHCI, or UHCI. UHCI was one of the first interfaces, designed by Intel and also used by VIA; it doesn't do much in hardware. OHCI was designed later, to have the hardware do more work (bigger transfers, tracking protocol state, and so on). EHCI was designed with USB 2.0; its design has features that resemble OHCI (hardware does much more work) as well as UHCI (some parts of ISO support, TD list processing). XHCI was designed with USB 3.0. It continues to shift support for functionality into hardware.

There are host controllers other than the "big three", although most PCI based controllers (and a few non-PCI based ones) use one of those interfaces. Not all host controllers use DMA; some use PIO, and there is also a simulator and a virtual host controller to pipe USB over the network.

The same basic APIs are available to drivers for all those controllers. For historical reasons they are in two layers: `struct usb_bus` is a rather thin layer that became available in the 2.2 kernels, while `struct usb_hcd` is a more featureful layer that lets HCDs share common code, to shrink driver size and significantly reduce hcd-specific behaviors.

long **usb_calc_bus_time**(int speed, int is_input, int isoc, int bytecount)
approximate periodic transaction time in nanoseconds

Parameters

int speed from dev->speed; USB_SPEED_{LOW,FULL,HIGH}

int is_input true iff the transaction sends data to the host

int isoc true for isochronous transactions, false for interrupt ones

int bytecount how many bytes in the transaction.

Return

Approximate bus time in nanoseconds for a periodic transaction.

Note

See USB 2.0 spec section 5.11.3; only periodic transfers need to be scheduled in software, this function is only used for such scheduling.

int **usb_hcd_link_urb_to_ep**(struct usb_hcd * hcd, struct urb * urb)
add an URB to its endpoint queue

Parameters

struct usb_hcd * hcd host controller to which **urb** was submitted

struct urb * urb URB being submitted

Description

Host controller drivers should call this routine in their enqueue() method. The HCD's private spinlock must be held and interrupts must be disabled. The actions carried out here are required for URB submission, as well as for endpoint shutdown and for usb_kill_urb.

Return

0 for no error, otherwise a negative error code (in which case the enqueue() method must fail). If no error occurs but enqueue() fails anyway, it must call `usb_hcd_unlink_urb_from_ep()` before releasing the private spinlock and returning.

int **usb_hcd_check_unlink_urb**(struct usb_hcd * hcd, struct urb * urb, int status)
check whether an URB may be unlinked

Parameters

struct usb_hcd * hcd host controller to which **urb** was submitted

struct urb * urb URB being checked for unlinkability

int status error code to store in **urb** if the unlink succeeds

Description

Host controller drivers should call this routine in their dequeue() method. The HCD's private spinlock must be held and interrupts must be disabled. The actions carried out here are required for making sure than an unlink is valid.

Return

0 for no error, otherwise a negative error code (in which case the dequeue() method must fail). The possible error codes are:

-EIDRM: urb was not submitted or has already completed. The completion function may not have been called yet.

-EBUSY: **urb** has already been unlinked.

void **usb_hcd_unlink_urb_from_ep**(struct usb_hcd * hcd, struct urb * urb)
remove an URB from its endpoint queue

Parameters

struct usb_hcd * hcd host controller to which **urb** was submitted

struct urb * urb URB being unlinked

Description

Host controller drivers should call this routine before calling `usb_hcd_giveback_urb()`. The HCD's private spinlock must be held and interrupts must be disabled. The actions carried out here are required for URB completion.

void **usb_hcd_giveback_urb**(struct usb_hcd * hcd, struct urb * urb, int status)
return URB from HCD to device driver

Parameters

struct usb_hcd * hcd host controller returning the URB

struct urb * urb urb being returned to the USB device driver.

int status completion status code for the URB.

Context

in_interrupt()

Description

This hands the URB from HCD to its USB device driver, using its completion function. The HCD has freed all per-urb resources (and is done using urb->hcpriv). It also released all HCD locks; the device driver won't cause problems if it frees, modifies, or resubmits this URB.

If **urb** was unlinked, the value of **status** will be overridden by **urb->unlinked**. Erroneous short transfers are detected in case the HCD hasn't checked for them.

int **usb_alloc_streams**(struct usb_interface * interface, struct usb_host_endpoint ** eps, unsigned int num_eps, unsigned int num_streams, gfp_t mem_flags)
allocate bulk endpoint stream IDs.

Parameters

struct usb_interface * interface alternate setting that includes all endpoints.

struct usb_host_endpoint ** eps array of endpoints that need streams.

unsigned int num_eps number of endpoints in the array.

unsigned int num_streams number of streams to allocate.

gfp_t mem_flags flags hcd should use to allocate memory.

Description

Sets up a group of bulk endpoints to have **num_streams** stream IDs available. Drivers may queue multiple transfers to different stream IDs, which may complete in a different order than they were queued.

Return

On success, the number of allocated streams. On failure, a negative error code.

int **usb_free_streams**(struct usb_interface * interface, struct usb_host_endpoint ** eps, unsigned int num_eps, gfp_t mem_flags)
free bulk endpoint stream IDs.

Parameters

struct usb_interface * interface alternate setting that includes all endpoints.

struct usb_host_endpoint ** eps array of endpoints to remove streams from.

unsigned int num_eps number of endpoints in the array.

gfp_t mem_flags flags hcd should use to allocate memory.

Description

Reverts a group of bulk endpoints back to not using stream IDs. Can fail if we are given bad arguments, or HCD is broken.

Return

0 on success. On failure, a negative error code.

void **usb_hcd_resume_root_hub**(struct usb_hcd * hcd)
called by HCD to resume its root hub

Parameters

struct usb_hcd * hcd host controller for this root hub

Description

The USB host controller calls this function when its root hub is suspended (with the remote wakeup feature enabled) and a remote wakeup request is received. The routine submits a workqueue request to resume the root hub (that is, manage its downstream ports again).

int **usb_bus_start_enum**(struct usb_bus * bus, unsigned port_num)
start immediate enumeration (for OTG)

Parameters

struct usb_bus * bus the bus (must use hcd framework)

unsigned port_num 1-based number of port; usually bus->otg_port

Context

in_interrupt()

Description

Starts enumeration, with an immediate reset followed later by hub_wq identifying and possibly configuring the device. This is needed by OTG controller drivers, where it helps meet HNP protocol timing requirements for starting a port reset.

Return

0 if successful.

irqreturn_t **usb_hcd_irq**(int irq, void * __hcd)
hook IRQs to HCD framework (bus glue)

Parameters

int irq the IRQ being raised

void * __hcd pointer to the HCD whose IRQ is being signaled

Description

If the controller isn't HALTed, calls the driver's irq handler. Checks whether the controller is now dead.

Return

`IRQ_HANDLED` if the IRQ was handled. `IRQ_NONE` otherwise.

void **usb_hc_died**(struct usb_hcd * hcd)
report abnormal shutdown of a host controller (bus glue)

Parameters

struct usb_hcd * hcd pointer to the HCD representing the controller

Description

This is called by bus glue to report a USB host controller that died while operations may still have been pending. It's called automatically by the PCI glue, so only glue for non-PCI busses should need to call it.

Only call this function with the primary HCD.

struct usb_hcd * **usb_create_shared_hcd**(const struct hc_driver * driver, struct device * dev, const char * bus_name, struct usb_hcd * primary_hcd)
create and initialize an HCD structure

Parameters

const struct hc_driver * driver HC driver that will use this hcd

struct device * dev device for this HC, stored in hcd->self.controller

const char * bus_name value to store in hcd->self.bus_name

struct usb_hcd * primary_hcd a pointer to the usb_hcd structure that is sharing the PCI device. Only allocate certain resources for the primary HCD

Context

!in_interrupt()

Description

Allocate a struct usb_hcd, with extra space at the end for the HC driver's private data. Initialize the generic members of the hcd structure.

Return

On success, a pointer to the created and initialized HCD structure. On failure (e.g. if memory is unavailable), `NULL`.

struct usb_hcd * **usb_create_hcd**(const struct hc_driver * driver, struct device * dev, const char * bus_name)
create and initialize an HCD structure

Parameters

const struct hc_driver * driver HC driver that will use this hcd

struct device * dev device for this HC, stored in hcd->self.controller

const char * bus_name value to store in hcd->self.bus_name

Context

!in_interrupt()

Description

Allocate a struct usb_hcd, with extra space at the end for the HC driver's private data. Initialize the generic members of the hcd structure.

Return

On success, a pointer to the created and initialized HCD structure. On failure (e.g. if memory is unavailable), `NULL`.

int **usb_add_hcd**(struct usb_hcd * hcd, unsigned int irqnum, unsigned long irqflags)
finish generic HCD structure initialization and register

Parameters

struct usb_hcd * hcd the usb_hcd structure to initialize

unsigned int irqnum Interrupt line to allocate

unsigned long irqflags Interrupt type flags

Description

Finish the remaining parts of generic HCD initialization: allocate the buffers of consistent memory, register the bus, request the IRQ line, and call the driver's reset() and start() routines.

void **usb_remove_hcd**(struct usb_hcd * hcd)
shutdown processing for generic HCDs

Parameters

struct usb_hcd * hcd the usb_hcd structure to remove

Context

!in_interrupt()

Description

Disconnects the root hub, then reverses the effects of `usb_add_hcd()`, invoking the HCD's stop() method.

int **usb_hcd_pci_probe**(struct pci_dev * dev, const struct pci_device_id * id, const struct hc_driver * driver)
initialize PCI-based HCDs

Parameters

struct pci_dev * dev USB Host Controller being probed

const struct pci_device_id * id pci hotplug id connecting controller to HCD framework

const struct hc_driver * driver USB HC driver handle

Context

!in_interrupt()

Description

Allocates basic PCI resources for this USB host controller, and then invokes the start() method for the HCD associated with it through the hotplug entry's driver_data.

Store this function in the HCD's struct pci_driver as probe().

Return

0 if successful.

void **usb_hcd_pci_remove**(struct pci_dev * dev)
shutdown processing for PCI-based HCDs

Parameters

struct pci_dev * dev USB Host Controller being removed

Context

!in_interrupt()

Description

Reverses the effect of `usb_hcd_pci_probe()`, first invoking the HCD's stop() method. It is always called from a thread context, normally "rmmod", "apmd", or something similar.

Store this function in the HCD's struct pci_driver as remove().

void **usb_hcd_pci_shutdown**(struct pci_dev * dev)
shutdown host controller

Parameters

struct pci_dev * dev USB Host Controller being shutdown

int **hcd_buffer_create**(struct usb_hcd * hcd)
initialize buffer pools

Parameters

struct usb_hcd * hcd the bus whose buffer pools are to be initialized

Context

!in_interrupt()

Description

Call this as part of initializing a host controller that uses the dma memory allocators. It initializes some pools of dma-coherent memory that will be shared by all drivers using that controller.

Call `hcd_buffer_destroy()` to clean up after using those pools.

Return

0 if successful. A negative errno value otherwise.

void **hcd_buffer_destroy**(struct usb_hcd * hcd)
deallocate buffer pools

Parameters

struct usb_hcd * hcd the bus whose buffer pools are to be destroyed

Context

!in_interrupt()

Description

This frees the buffer pools created by `hcd_buffer_create()`.

20.1.7 The USB character device nodes

This chapter presents the Linux character device nodes. You may prefer to avoid writing new kernel code for your USB driver. User mode device drivers are usually packaged as applications or libraries, and may use character devices through some programming library that wraps it. Such libraries include:

- libusb for C/C++, and
- jUSB for Java.

Some old information about it can be seen at the "USB Device Filesystem" section of the USB Guide. The latest copy of the USB Guide can be found at http://www.linux-usb.org/

Note:

- They were used to be implemented via usbfs, but this is not part of the sysfs debug interface.
- This particular documentation is incomplete, especially with respect to the asynchronous mode. As of kernel 2.5.66 the code and this (new) documentation need to be cross-reviewed.

What files are in "devtmpfs"?

Conventionally mounted at `/dev/bus/usb/`, usbfs features include:

- `/dev/bus/usb/BBB/DDD` ⋯magic files exposing the each device's configuration descriptors, and supporting a series of ioctls for making device requests, including I/O to devices. (Purely for access by programs.)

Each bus is given a number (`BBB`) based on when it was enumerated; within each bus, each device is given a similar number (`DDD`). Those `BBB/DDD` paths are not "stable" identifiers; expect them to change even if you always leave the devices plugged in to the same hub port. Don't even think of saving these in application configuration files. Stable identifiers are available, for user mode applications that want to use them. HID and networking devices expose these stable IDs, so that for example you can be sure that you told the right UPS to power down its second server. Pleast note that it doesn't (yet) expose those IDs.

/dev/bus/usb/BBB/DDD

Use these files in one of these basic ways:

- They can be read, producing first the device descriptor (18 bytes) and then the descriptors for the current configuration. See the USB 2.0 spec for details about those binary data formats. You'll need to convert most multibyte values from little endian format to your native host byte order, although a few of the fields in the device descriptor (both of the BCD-encoded fields, and the vendor and product IDs) will be byteswapped for you. Note that configuration descriptors include descriptors for interfaces, altsettings, endpoints, and maybe additional class descriptors.

- Perform USB operations using ioctl() requests to make endpoint I/O requests (synchronously or asynchronously) or manage the device. These requests need the CAP_SYS_RAWIO capability, as well as filesystem access permissions. Only one ioctl request can be made on one of these device files at a time. This means that if you are synchronously reading an endpoint from one thread, you won't be able to write to a different endpoint from another thread until the read completes. This works for half duplex protocols, but otherwise you'd use asynchronous i/o requests.

Each connected USB device has one file. The BBB indicates the bus number. The DDD indicates the device address on that bus. Both of these numbers are assigned sequentially, and can be reused, so you can't rely on them for stable access to devices. For example, it's relatively common for devices to re-enumerate while they are still connected (perhaps someone jostled their power supply, hub, or USB cable), so a device might be 002/027 when you first connect it and 002/048 sometime later.

These files can be read as binary data. The binary data consists of first the device descriptor, then the descriptors for each configuration of the device. Multi-byte fields in the device descriptor are converted to host endianness by the kernel. The configuration descriptors are in bus endian format! The configuration descriptor are wTotalLength bytes apart. If a device returns less configuration descriptor data than indicated by wTotalLength there will be a hole in the file for the missing bytes. This information is also shown in text form by the /sys/kernel/debug/usb/devices file, described later.

These files may also be used to write user-level drivers for the USB devices. You would open the /dev/bus/usb/BBB/DDD file read/write, read its descriptors to make sure it's the device you expect, and then bind to an interface (or perhaps several) using an ioctl call. You would issue more ioctls to the device to communicate to it using control, bulk, or other kinds of USB transfers. The IOCTLs are listed in the <linux/usbdevice_fs.h> file, and at this writing the source code (linux/drivers/usb/core/devio.c) is the primary reference for how to access devices through those files.

Note that since by default these BBB/DDD files are writable only by root, only root can write such user mode drivers. You can selectively grant read/write permissions to other users by using chmod. Also, usbfs mount options such as devmode=0666 may be helpful.

Life Cycle of User Mode Drivers

Such a driver first needs to find a device file for a device it knows how to handle. Maybe it was told about it because a /sbin/hotplug event handling agent chose that driver to handle the new device. Or maybe it's an application that scans all the /dev/bus/usb device files, and ignores most devices. In either case, it should read() all the descriptors from the device file, and check them against what it knows how to handle. It might just reject everything except a particular vendor and product ID, or need a more complex policy.

Never assume there will only be one such device on the system at a time! If your code can't handle more than one device at a time, at least detect when there's more than one, and have your users choose which device to use.

Once your user mode driver knows what device to use, it interacts with it in either of two styles. The simple style is to make only control requests; some devices don't need more complex interactions than those. (An example might be software using vendor-specific control requests for some initialization or configuration tasks, with a kernel driver for the rest.)

More likely, you need a more complex style driver: one using non-control endpoints, reading or writing data and claiming exclusive use of an interface. Bulk transfers are easiest to use, but only their sibling interrupt transfers work with low speed devices. Both interrupt and isochronous transfers offer service guarantees because their bandwidth is reserved. Such "periodic" transfers are awkward to use through usbfs, unless you're using the asynchronous calls. However, interrupt transfers can also be used in a synchronous "one shot" style.

Your user-mode driver should never need to worry about cleaning up request state when the device is disconnected, although it should close its open file descriptors as soon as it starts seeing the ENODEV errors.

The ioctl() Requests

To use these ioctls, you need to include the following headers in your userspace program:

```
#include <linux/usb.h>
#include <linux/usbdevice_fs.h>
#include <asm/byteorder.h>
```

The standard USB device model requests, from "Chapter 9" of the USB 2.0 specification, are automatically included from the `<linux/usb/ch9.h>` header.

Unless noted otherwise, the ioctl requests described here will update the modification time on the usbfs file to which they are applied (unless they fail). A return of zero indicates success; otherwise, a standard USB error code is returned (These are documented in USB Error codes).

Each of these files multiplexes access to several I/O streams, one per endpoint. Each device has one control endpoint (endpoint zero) which supports a limited RPC style RPC access. Devices are configured by hub_wq (in the kernel) setting a device-wide configuration that affects things like power consumption and basic functionality. The endpoints are part of USB interfaces, which may have altsettings affecting things like which endpoints are available. Many devices only have a single configuration and interface, so drivers for them will ignore configurations and altsettings.

Management/Status Requests

A number of usbfs requests don't deal very directly with device I/O. They mostly relate to device management and status. These are all synchronous requests.

USBDEVFS_CLAIMINTERFACE This is used to force usbfs to claim a specific interface, which has not previously been claimed by usbfs or any other kernel driver. The ioctl parameter is an integer holding the number of the interface (bInterfaceNumber from descriptor).

Note that if your driver doesn't claim an interface before trying to use one of its endpoints, and no other driver has bound to it, then the interface is automatically claimed by usbfs.

This claim will be released by a RELEASEINTERFACE ioctl, or by closing the file descriptor. File modification time is not updated by this request.

USBDEVFS_CONNECTINFO Says whether the device is lowspeed. The ioctl parameter points to a structure like this:

```
struct usbdevfs_connectinfo {
        unsigned int   devnum;
        unsigned char  slow;
};
```

File modification time is not updated by this request.

You can't tell whether a "not slow" device is connected at high speed (480 MBit/sec) or just full speed (12 MBit/sec). You should know the devnum value already, it's the DDD value of the device file name.

USBDEVFS_GETDRIVER Returns the name of the kernel driver bound to a given interface (a string). Parameter is a pointer to this structure, which is modified:

```
struct usbdevfs_getdriver {
        unsigned int  interface;
        char          driver[USBDEVFS_MAXDRIVERNAME + 1];
};
```

File modification time is not updated by this request.

USBDEVFS_IOCTL Passes a request from userspace through to a kernel driver that has an ioctl entry in the struct usb_driver it registered:

```
struct usbdevfs_ioctl {
        int     ifno;
        int     ioctl_code;
        void    *data;
};

/* user mode call looks like this.
 * 'request' becomes the driver->ioctl() 'code' parameter.
 * the size of 'param' is encoded in 'request', and that data
 * is copied to or from the driver->ioctl() 'buf' parameter.
 */
static int
```

(continues on next page)

(continued from previous page)

```
usbdev_ioctl (int fd, int ifno, unsigned request, void *param)
{
        struct usbdevfs_ioctl   wrapper;

        wrapper.ifno = ifno;
        wrapper.ioctl_code = request;
        wrapper.data = param;

        return ioctl (fd, USBDEVFS_IOCTL, &wrapper);
}
```

File modification time is not updated by this request.

This request lets kernel drivers talk to user mode code through filesystem operations even when they don't create a character or block special device. It's also been used to do things like ask devices what device special file should be used. Two pre-defined ioctls are used to disconnect and reconnect kernel drivers, so that user mode code can completely manage binding and configuration of devices.

USBDEVFS_RELEASEINTERFACE This is used to release the claim usbfs made on interface, either implicitly or because of a USBDEVFS_CLAIMINTERFACE call, before the file descriptor is closed. The ioctl parameter is an integer holding the number of the interface (bInterfaceNumber from descriptor); File modification time is not updated by this request.

> **Warning:** No security check is made to ensure that the task which made the claim is the one which is releasing it. This means that user mode driver may interfere other ones.

USBDEVFS_RESETEP Resets the data toggle value for an endpoint (bulk or interrupt) to DATA0. The ioctl parameter is an integer endpoint number (1 to 15, as identified in the endpoint descriptor), with USB_DIR_IN added if the device's endpoint sends data to the host.

> **Warning:** Avoid using this request. It should probably be removed. Using it typically means the device and driver will lose toggle synchronization. If you really lost synchronization, you likely need to completely handshake with the device, using a request like CLEAR_HALT or SET_INTERFACE.

USBDEVFS_DROP_PRIVILEGES This is used to relinquish the ability to do certain operations which are considered to be privileged on a usbfs file descriptor. This includes claiming arbitrary interfaces, resetting a device on which there are currently claimed interfaces from other users, and issuing USBDEVFS_IOCTL calls. The ioctl parameter is a 32 bit mask of interfaces the user is allowed to claim on this file descriptor. You may issue this ioctl more than one time to narrow said mask.

Synchronous I/O Support

Synchronous requests involve the kernel blocking until the user mode request completes, either by finishing successfully or by reporting an error. In most cases this is the simplest way to use usbfs, although as noted above it does prevent performing I/O to more than one endpoint at a time.

USBDEVFS_BULK Issues a bulk read or write request to the device. The ioctl parameter is a pointer to this structure:

```
struct usbdevfs_bulktransfer {
        unsigned int  ep;
        unsigned int  len;
        unsigned int  timeout; /* in milliseconds */
        void          *data;
};
```

The `ep` value identifies a bulk endpoint number (1 to 15, as identified in an endpoint descriptor), masked with USB_DIR_IN when referring to an endpoint which sends data to the host from the device. The length of the data buffer is identified by `len`; Recent kernels support requests up to about 128KBytes. FIXME say how read length is returned, and how short reads are handled..

USBDEVFS_CLEAR_HALT Clears endpoint halt (stall) and resets the endpoint toggle. This is only meaningful for bulk or interrupt endpoints. The ioctl parameter is an integer endpoint number (1 to 15, as identified in an endpoint descriptor), masked with USB_DIR_IN when referring to an endpoint which sends data to the host from the device.

Use this on bulk or interrupt endpoints which have stalled, returning `-EPIPE` status to a data transfer request. Do not issue the control request directly, since that could invalidate the host's record of the data toggle.

USBDEVFS_CONTROL Issues a control request to the device. The ioctl parameter points to a structure like this:

```
struct usbdevfs_ctrltransfer {
        __u8   bRequestType;
        __u8   bRequest;
        __u16  wValue;
        __u16  wIndex;
        __u16  wLength;
        __u32  timeout;  /* in milliseconds */
        void   *data;
};
```

The first eight bytes of this structure are the contents of the SETUP packet to be sent to the device; see the USB 2.0 specification for details. The bRequestType value is composed by combining a `USB_TYPE_*` value, a `USB_DIR_*` value, and a `USB_RECIP_*` value (from `linux/usb.h`). If wLength is nonzero, it describes the length of the data buffer, which is either written to the device (USB_DIR_OUT) or read from the device (USB_DIR_IN).

At this writing, you can't transfer more than 4 KBytes of data to or from a device; usbfs has a limit, and some host controller drivers have a limit. (That'

s not usually a problem.) Also there's no way to say it's not OK to get a short read back from the device.

USBDEVFS_RESET Does a USB level device reset. The ioctl parameter is ignored. After the reset, this rebinds all device interfaces. File modification time is not updated by this request.

Warning: Avoid using this call until some usbcore bugs get fixed, since it does not fully synchronize device, interface, and driver (not just usbfs) state.

USBDEVFS_SETINTERFACE Sets the alternate setting for an interface. The ioctl parameter is a pointer to a structure like this:

```
struct usbdevfs_setinterface {
        unsigned int  interface;
        unsigned int  altsetting;
};
```

File modification time is not updated by this request.

Those struct members are from some interface descriptor applying to the current configuration. The interface number is the bInterfaceNumber value, and the altsetting number is the bAlternateSetting value. (This resets each endpoint in the interface.)

USBDEVFS_SETCONFIGURATION Issues the `usb_set_configuration()` call for the device. The parameter is an integer holding the number of a configuration (bConfigurationValue from descriptor). File modification time is not updated by this request.

Warning: Avoid using this call until some usbcore bugs get fixed, since it does not fully synchronize device, interface, and driver (not just usbfs) state.

Asynchronous I/O Support

As mentioned above, there are situations where it may be important to initiate concurrent operations from user mode code. This is particularly important for periodic transfers (interrupt and isochronous), but it can be used for other kinds of USB requests too. In such cases, the asynchronous requests described here are essential. Rather than submitting one request and having the kernel block until it completes, the blocking is separate.

These requests are packaged into a structure that resembles the URB used by kernel device drivers. (No POSIX Async I/O support here, sorry.) It identifies the endpoint type (`USBDEVFS_URB_TYPE_*`), endpoint (number, masked with USB_DIR_IN as appropriate), buffer and length, and a user "context" value serving to uniquely identify each request. (It's usually a pointer to per-request data.) Flags can modify requests (not as many as supported for kernel drivers).

Each request can specify a realtime signal number (between SIGRTMIN and SIGRTMAX, inclusive) to request a signal be sent when the request completes.

When usbfs returns these urbs, the status value is updated, and the buffer may have been modified. Except for isochronous transfers, the actual_length is updated to say how many bytes were transferred; if the USBDEVFS_URB_DISABLE_SPD flag is set (“short packets are not OK”), if fewer bytes were read than were requested then you get an error report:

```
struct usbdevfs_iso_packet_desc {
        unsigned int                    length;
        unsigned int                    actual_length;
        unsigned int                    status;
};

struct usbdevfs_urb {
        unsigned char                   type;
        unsigned char                   endpoint;
        int                             status;
        unsigned int                    flags;
        void                            *buffer;
        int                             buffer_length;
        int                             actual_length;
        int                             start_frame;
        int                             number_of_packets;
        int                             error_count;
        unsigned int                    signr;
        void                            *usercontext;
        struct usbdevfs_iso_packet_desc  iso_frame_desc[];
};
```

For these asynchronous requests, the file modification time reflects when the request was initiated. This contrasts with their use with the synchronous requests, where it reflects when requests complete.

USBDEVFS_DISCARDURB TBS File modification time is not updated by this request.

USBDEVFS_DISCSIGNAL TBS File modification time is not updated by this request.

USBDEVFS_REAPURB TBS File modification time is not updated by this request.

USBDEVFS_REAPURBNDELAY TBS File modification time is not updated by this request.

USBDEVFS_SUBMITURB TBS

20.1.8 The USB devices

The USB devices are now exported via debugfs:

- `/sys/kernel/debug/usb/devices` ⋯a text file showing each of the USB devices on known to the kernel, and their configuration descriptors. You can also poll() this to learn about new devices.

/sys/kernel/debug/usb/devices

This file is handy for status viewing tools in user mode, which can scan the text format and ignore most of it. More detailed device status (including class and vendor status) is available from device-specific files. For information about the current format of this file, see below.

This file, in combination with the poll() system call, can also be used to detect when devices are added or removed:

```
int fd;
struct pollfd pfd;

fd = open("/sys/kernel/debug/usb/devices", O_RDONLY);
pfd = { fd, POLLIN, 0 };
for (;;) {
    /* The first time through, this call will return immediately. */
    poll(&pfd, 1, -1);

    /* To see what's changed, compare the file's previous and current
       contents or scan the filesystem.  (Scanning is more precise.) */
}
```

Note that this behavior is intended to be used for informational and debug purposes. It would be more appropriate to use programs such as udev or HAL to initialize a device or start a user-mode helper program, for instance.

In this file, each device's output has multiple lines of ASCII output.

I made it ASCII instead of binary on purpose, so that someone can obtain some useful data from it without the use of an auxiliary program. However, with an auxiliary program, the numbers in the first 4 columns of each `T:` line (topology info: Lev, Prnt, Port, Cnt) can be used to build a USB topology diagram.

Each line is tagged with a one-character ID for that line:

```
T = Topology (etc.)
B = Bandwidth (applies only to USB host controllers, which are
virtualized as root hubs)
D = Device descriptor info.
P = Product ID info. (from Device descriptor, but they won't fit
together on one line)
S = String descriptors.
C = Configuration descriptor info. (* = active configuration)
I = Interface descriptor info.
E = Endpoint descriptor info.
```

/sys/kernel/debug/usb/devices output format

Legend:: d = decimal number (may have leading spaces or 0’s) x = hexadecimal number (may have leading spaces or 0’s) s = string

Topology info

```
T:  Bus=dd Lev=dd Prnt=dd Port=dd Cnt=dd Dev#=ddd Spd=dddd MxCh=dd
|   |      |      |       |       |      |         |        |__MaxChildren
|   |      |      |       |       |      |         |__Device Speed in Mbps
|   |      |      |       |       |      |__DeviceNumber
|   |      |      |       |       |__Count of devices at this level
|   |      |      |       |__Connector/Port on Parent for this device
|   |      |      |__Parent DeviceNumber
|   |      |__Level in topology for this bus
|   |__Bus number
|__Topology info tag
```

Speed may be:

1.5	Mbit/s for low speed USB
12	Mbit/s for full speed USB
480	Mbit/s for high speed USB (added for USB 2.0); also used for Wireless USB, which has no fixed speed
5000	Mbit/s for SuperSpeed USB (added for USB 3.0)

For reasons lost in the mists of time, the Port number is always too low by 1. For example, a device plugged into port 4 will show up with `Port=03`.

Bandwidth info

```
B:  Alloc=ddd/ddd us (xx%), #Int=ddd, #Iso=ddd
|   |                       |         |__Number of isochronous requests
|   |                       |__Number of interrupt requests
|   |__Total Bandwidth allocated to this bus
|__Bandwidth info tag
```

Bandwidth allocation is an approximation of how much of one frame (millisecond) is in use. It reflects only periodic transfers, which are the only transfers that reserve bandwidth. Control and bulk transfers use all other bandwidth, including reserved bandwidth that is not used for transfers (such as for short packets).

The percentage is how much of the “reserved” bandwidth is scheduled by those transfers. For a low or full speed bus (loosely, “USB 1.1”), 90% of the bus bandwidth is reserved. For a high speed bus (loosely, “USB 2.0”) 80% is reserved.

Device descriptor info & Product ID info

```
D:  Ver=x.xx Cls=xx(s) Sub=xx Prot=xx MxPS=dd #Cfgs=dd
P:  Vendor=xxxx ProdID=xxxx Rev=xx.xx
```

where:

```
D:  Ver=x.xx Cls=xx(sssss) Sub=xx Prot=xx MxPS=dd #Cfgs=dd
|   |        |             |      |       |       |__NumberConfigurations
|   |        |             |      |       |__MaxPacketSize of Default␣
↪Endpoint
|   |        |             |      |__DeviceProtocol
|   |        |             |__DeviceSubClass
|   |        |__DeviceClass
|   |__Device USB version
|__Device info tag #1
```

where:

```
P:  Vendor=xxxx ProdID=xxxx Rev=xx.xx
|   |           |           |__Product revision number
|   |           |__Product ID code
|   |__Vendor ID code
|__Device info tag #2
```

String descriptor info

```
S:  Manufacturer=ssss
|   |__Manufacturer of this device as read from the device.
|      For USB host controller drivers (virtual root hubs) this may
|      be omitted, or (for newer drivers) will identify the kernel
|      version and the driver which provides this hub emulation.
|__String info tag

S:  Product=ssss
|   |__Product description of this device as read from the device.
|      For older USB host controller drivers (virtual root hubs) this
|      indicates the driver; for newer ones, it's a product (and vendor)
|      description that often comes from the kernel's PCI ID database.
|__String info tag

S:  SerialNumber=ssss
|   |__Serial Number of this device as read from the device.
|      For USB host controller drivers (virtual root hubs) this is
|      some unique ID, normally a bus ID (address or slot name) that
|      can't be shared with any other device.
|__String info tag
```

Configuration descriptor info

```
C:* #Ifs=dd Cfg#=dd Atr=xx MPwr=dddmA
| | |       |       |      |__MaxPower in mA
| | |       |       |__Attributes
| | |       |__ConfigurationNumber
| | |__NumberOfInterfaces
| |__ "*" indicates the active configuration (others are " ")
|__Config info tag
```

USB devices may have multiple configurations, each of which act rather differently. For example, a bus-powered configuration might be much less capable than one that is self-powered. Only one device configuration can be active at a time; most devices have only one configuration.

Each configuration consists of one or more interfaces. Each interface serves a distinct "function", which is typically bound to a different USB device driver. One common example is a USB speaker with an audio interface for playback, and a HID interface for use with software volume control.

Interface descriptor info (can be multiple per Config)

```
I:* If#=dd Alt=dd #EPs=dd Cls=xx(sssss) Sub=xx Prot=xx Driver=ssss
| | |      |      |       |             |      |       |__Driver name
| | |      |      |       |             |      |          or "(none)"
| | |      |      |       |             |      |__InterfaceProtocol
| | |      |      |       |             |__InterfaceSubClass
| | |      |      |       |__InterfaceClass
| | |      |      |__NumberOfEndpoints
| | |      |__AlternateSettingNumber
| | |__InterfaceNumber
| |__ "*" indicates the active altsetting (others are " ")
|__Interface info tag
```

A given interface may have one or more "alternate" settings. For example, default settings may not use more than a small amount of periodic bandwidth. To use significant fractions of bus bandwidth, drivers must select a non-default altsetting.

Only one setting for an interface may be active at a time, and only one driver may bind to an interface at a time. Most devices have only one alternate setting per interface.

Endpoint descriptor info (can be multiple per Interface)

```
E:  Ad=xx(s) Atr=xx(ssss) MxPS=dddd Ivl=dddss
|   |        |            |         |__Interval (max) between transfers
|   |        |            |__EndpointMaxPacketSize
|   |        |__Attributes(EndpointType)
|   |__EndpointAddress(I=In,O=Out)
|__Endpoint info tag
```

The interval is nonzero for all periodic (interrupt or isochronous) endpoints. For high speed endpoints the transfer interval may be measured in microseconds rather than milliseconds.

For high speed periodic endpoints, the `EndpointMaxPacketSize` reflects the per-microframe data transfer size. For "high bandwidth" endpoints, that can reflect two or three packets (for up to 3KBytes every 125 usec) per endpoint.

With the Linux-USB stack, periodic bandwidth reservations use the transfer intervals and sizes provided by URBs, which can be less than those found in endpoint descriptor.

Usage examples

If a user or script is interested only in Topology info, for example, use something like `grep ^T: /sys/kernel/debug/usb/devices` for only the Topology lines. A command like `grep -i ^[tdp]: /sys/kernel/debug/usb/devices` can be used to list only the lines that begin with the characters in square brackets, where the valid characters are TDPCIE. With a slightly more able script, it can display any selected lines (for example, only T, D, and P lines) and change their output format. (The `procusb` Perl script is the beginning of this idea. It will list only selected lines [selected from TBDPSCIE] or "All" lines from `/sys/kernel/debug/usb/devices`.)

The Topology lines can be used to generate a graphic/pictorial of the USB devices on a system's root hub. (See more below on how to do this.)

The Interface lines can be used to determine what driver is being used for each device, and which altsetting it activated.

The Configuration lines could be used to list maximum power (in milliamps) that a system's USB devices are using. For example, `grep ^C: /sys/kernel/debug/usb/devices`.

Here's an example, from a system which has a UHCI root hub, an external hub connected to the root hub, and a mouse and a serial converter connected to the external hub.

```

20.2 USB Gadget API for Linux

Author David Brownell

Date 20 August 2004

20.2.1 Introduction

This document presents a Linux-USB "Gadget" kernel mode API, for use within peripherals and other USB devices that embed Linux. It provides an overview of the API structure, and shows how that fits into a system development project. This is the first such API released on Linux to address a number of important problems, including:

- Supports USB 2.0, for high speed devices which can stream data at several dozen megabytes per second.
- Handles devices with dozens of endpoints just as well as ones with just two fixed-function ones. Gadget drivers can be written so they're easy to port to new hardware.
- Flexible enough to expose more complex USB device capabilities such as multiple configurations, multiple interfaces, composite devices, and alternate interface settings.
- USB "On-The-Go" (OTG) support, in conjunction with updates to the Linux-USB host side.
- Sharing data structures and API models with the Linux-USB host side API. This helps the OTG support, and looks forward to more-symmetric frameworks (where the same I/O model is used by both host and device side drivers).
- Minimalist, so it's easier to support new device controller hardware. I/O processing doesn't imply large demands for memory or CPU resources.

Most Linux developers will not be able to use this API, since they have USB `host` hardware in a PC, workstation, or server. Linux users with embedded systems are more likely to have USB peripheral hardware. To distinguish drivers running inside such hardware from the more familiar Linux "USB device drivers", which are host side proxies for the real USB devices, a different term is used: the drivers inside the peripherals are "USB gadget drivers". In USB protocol interactions, the device driver is the master (or "client driver") and the gadget driver is the slave (or "function driver").

The gadget API resembles the host side Linux-USB API in that both use queues of request objects to package I/O buffers, and those requests may be submitted or

canceled. They share common definitions for the standard USB Chapter 9 messages, structures, and constants. Also, both APIs bind and unbind drivers to devices. The APIs differ in detail, since the host side's current URB framework exposes a number of implementation details and assumptions that are inappropriate for a gadget API. While the model for control transfers and configuration management is necessarily different (one side is a hardware-neutral master, the other is a hardware-aware slave), the endpoint I/0 API used here should also be usable for an overhead-reduced host side API.

20.2.2 Structure of Gadget Drivers

A system running inside a USB peripheral normally has at least three layers inside the kernel to handle USB protocol processing, and may have additional layers in user space code. The `gadget` API is used by the middle layer to interact with the lowest level (which directly handles hardware).

In Linux, from the bottom up, these layers are:

USB Controller Driver This is the lowest software level. It is the only layer that talks to hardware, through registers, fifos, dma, irqs, and the like. The `<linux/usb/gadget.h>` API abstracts the peripheral controller endpoint hardware. That hardware is exposed through endpoint objects, which accept streams of IN/OUT buffers, and through callbacks that interact with gadget drivers. Since normal USB devices only have one upstream port, they only have one of these drivers. The controller driver can support any number of different gadget drivers, but only one of them can be used at a time.

Examples of such controller hardware include the PCI-based NetChip 2280 USB 2.0 high speed controller, the SA-11x0 or PXA-25x UDC (found within many PDAs), and a variety of other products.

Gadget Driver The lower boundary of this driver implements hardware-neutral USB functions, using calls to the controller driver. Because such hardware varies widely in capabilities and restrictions, and is used in embedded environments where space is at a premium, the gadget driver is often configured at compile time to work with endpoints supported by one particular controller. Gadget drivers may be portable to several different controllers, using conditional compilation. (Recent kernels substantially simplify the work involved in supporting new hardware, by autoconfiguring endpoints automatically for many bulk-oriented drivers.) Gadget driver responsibilities include:

- handling setup requests (ep0 protocol responses) possibly including class-specific functionality
- returning configuration and string descriptors
- (re)setting configurations and interface altsettings, including enabling and configuring endpoints
- handling life cycle events, such as managing bindings to hardware, USB suspend/resume, remote wakeup, and disconnection from the USB host.
- managing IN and OUT transfers on all currently enabled endpoints

Such drivers may be modules of proprietary code, although that approach is discouraged in the Linux community.

Upper Level Most gadget drivers have an upper boundary that connects to some Linux driver or framework in Linux. Through that boundary flows the data which the gadget driver produces and/or consumes through protocol transfers over USB. Examples include:

- user mode code, using generic (gadgetfs) or application specific files in `/dev`
- networking subsystem (for network gadgets, like the CDC Ethernet Model gadget driver)
- data capture drivers, perhaps video4Linux or a scanner driver; or test and measurement hardware.
- input subsystem (for HID gadgets)
- sound subsystem (for audio gadgets)
- file system (for PTP gadgets)
- block i/o subsystem (for usb-storage gadgets)
- ···and more

Additional Layers Other layers may exist. These could include kernel layers, such as network protocol stacks, as well as user mode applications building on standard POSIX system call APIs such as `open()`, `close()`, `read()` and `write()`. On newer systems, POSIX Async I/O calls may be an option. Such user mode code will not necessarily be subject to the GNU General Public License (GPL).

OTG-capable systems will also need to include a standard Linux-USB host side stack, with `usbcore`, one or more Host Controller Drivers (HCDs), USB Device Drivers to support the OTG "Targeted Peripheral List", and so forth. There will also be an OTG Controller Driver, which is visible to gadget and device driver developers only indirectly. That helps the host and device side USB controllers implement the two new OTG protocols (HNP and SRP). Roles switch (host to peripheral, or vice versa) using HNP during USB suspend processing, and SRP can be viewed as a more battery-friendly kind of device wakeup protocol.

Over time, reusable utilities are evolving to help make some gadget driver tasks simpler. For example, building configuration descriptors from vectors of descriptors for the configurations interfaces and endpoints is now automated, and many drivers now use autoconfiguration to choose hardware endpoints and initialize their descriptors. A potential example of particular interest is code implementing standard USB-IF protocols for HID, networking, storage, or audio classes. Some developers are interested in KDB or KGDB hooks, to let target hardware be remotely debugged. Most such USB protocol code doesn't need to be hardware-specific, any more than network protocols like X11, HTTP, or NFS are. Such gadget-side interface drivers should eventually be combined, to implement composite devices.

20.2.3 Kernel Mode Gadget API

Gadget drivers declare themselves through a struct `usb_gadget_driver`, which is responsible for most parts of enumeration for a struct `usb_gadget`. The response to a set_configuration usually involves enabling one or more of the struct `usb_ep` objects exposed by the gadget, and submitting one or more struct `usb_request` buffers to transfer data. Understand those four data types, and their operations, and you will understand how this API works.

Note: Other than the "Chapter 9" data types, most of the significant data types and functions are described here.

However, some relevant information is likely omitted from what you are reading. One example of such information is endpoint autoconfiguration. You'll have to read the header file, and use example source code (such as that for "Gadget Zero"), to fully understand the API.

The part of the API implementing some basic driver capabilities is specific to the version of the Linux kernel that's in use. The 2.6 and upper kernel versions include a driver model framework that has no analogue on earlier kernels; so those parts of the gadget API are not fully portable. (They are implemented on 2.4 kernels, but in a different way.) The driver model state is another part of this API that is ignored by the kerneldoc tools.

The core API does not expose every possible hardware feature, only the most widely available ones. There are significant hardware features, such as device-to-device DMA (without temporary storage in a memory buffer) that would be added using hardware-specific APIs.

This API allows drivers to use conditional compilation to handle endpoint capabilities of different hardware, but doesn't require that. Hardware tends to have arbitrary restrictions, relating to transfer types, addressing, packet sizes, buffering, and availability. As a rule, such differences only matter for "endpoint zero" logic that handles device configuration and management. The API supports limited run-time detection of capabilities, through naming conventions for endpoints. Many drivers will be able to at least partially autoconfigure themselves. In particular, driver init sections will often have endpoint autoconfiguration logic that scans the hardware's list of endpoints to find ones matching the driver requirements (relying on those conventions), to eliminate some of the most common reasons for conditional compilation.

Like the Linux-USB host side API, this API exposes the "chunky" nature of USB messages: I/O requests are in terms of one or more "packets", and packet boundaries are visible to drivers. Compared to RS-232 serial protocols, USB resembles synchronous protocols like HDLC (N bytes per frame, multipoint addressing, host as the primary station and devices as secondary stations) more than asynchronous ones (tty style: 8 data bits per frame, no parity, one stop bit). So for example the controller drivers won't buffer two single byte writes into a single two-byte USB IN packet, although gadget drivers may do so when they implement protocols where packet boundaries (and "short packets") are not significant.

Driver Life Cycle

Gadget drivers make endpoint I/O requests to hardware without needing to know many details of the hardware, but driver setup/configuration code needs to handle some differences. Use the API like this:

1. Register a driver for the particular device side usb controller hardware, such as the net2280 on PCI (USB 2.0), sa11x0 or pxa25x as found in Linux PDAs, and so on. At this point the device is logically in the USB ch9 initial state (`attached`), drawing no power and not usable (since it does not yet support enumeration). Any host should not see the device, since it's not activated the data line pullup used by the host to detect a device, even if VBUS power is available.

2. Register a gadget driver that implements some higher level device function. That will then bind() to a `usb_gadget`, which activates the data line pullup sometime after detecting VBUS.

3. The hardware driver can now start enumerating. The steps it handles are to accept USB `power` and `set_address` requests. Other steps are handled by the gadget driver. If the gadget driver module is unloaded before the host starts to enumerate, steps before step 7 are skipped.

4. The gadget driver's `setup()` call returns usb descriptors, based both on what the bus interface hardware provides and on the functionality being implemented. That can involve alternate settings or configurations, unless the hardware prevents such operation. For OTG devices, each configuration descriptor includes an OTG descriptor.

5. The gadget driver handles the last step of enumeration, when the USB host issues a `set_configuration` call. It enables all endpoints used in that configuration, with all interfaces in their default settings. That involves using a list of the hardware's endpoints, enabling each endpoint according to its descriptor. It may also involve using `usb_gadget_vbus_draw` to let more power be drawn from VBUS, as allowed by that configuration. For OTG devices, setting a configuration may also involve reporting HNP capabilities through a user interface.

6. Do real work and perform data transfers, possibly involving changes to interface settings or switching to new configurations, until the device is disconnect()ed from the host. Queue any number of transfer requests to each endpoint. It may be suspended and resumed several times before being disconnected. On disconnect, the drivers go back to step 3 (above).

7. When the gadget driver module is being unloaded, the driver unbind() callback is issued. That lets the controller driver be unloaded.

Drivers will normally be arranged so that just loading the gadget driver module (or statically linking it into a Linux kernel) allows the peripheral device to be enumerated, but some drivers will defer enumeration until some higher level component (like a user mode daemon) enables it. Note that at this lowest level there are no policies about how ep0 configuration logic is implemented, except that it should obey USB specifications. Such issues are in the domain of gadget drivers, including knowing about implementation constraints imposed by some USB controllers or understanding that composite devices might happen to be built by integrating

reusable components.

Note that the lifecycle above can be slightly different for OTG devices. Other than providing an additional OTG descriptor in each configuration, only the HNP-related differences are particularly visible to driver code. They involve reporting requirements during the `SET_CONFIGURATION` request, and the option to invoke HNP during some suspend callbacks. Also, SRP changes the semantics of `usb_gadget_wakeup` slightly.

USB 2.0 Chapter 9 Types and Constants

Gadget drivers rely on common USB structures and constants defined in the linux/usb/ch9.h header file, which is standard in Linux 2.6+ kernels. These are the same types and constants used by host side drivers (and usbcore).

Core Objects and Methods

These are declared in `<linux/usb/gadget.h>`, and are used by gadget drivers to interact with USB peripheral controller drivers.

struct **usb_request**
describes one i/o request

Definition

```
struct usb_request {
  void *buf;
  unsigned length;
  dma_addr_t dma;
  struct scatterlist      *sg;
  unsigned num_sgs;
  unsigned num_mapped_sgs;
  unsigned stream_id:16;
  unsigned is_last:1;
  unsigned no_interrupt:1;
  unsigned zero:1;
  unsigned short_not_ok:1;
  unsigned dma_mapped:1;
  void (*complete)(struct usb_ep *ep, struct usb_request *req);
  void *context;
  struct list_head        list;
  unsigned frame_number;
  int status;
  unsigned actual;
};
```

Members

buf Buffer used for data. Always provide this; some controllers only use PIO, or don't use DMA for some endpoints.

length Length of that data

dma DMA address corresponding to 'buf'. If you don't set this field, and the usb controller needs one, it is responsible for mapping and unmapping the buffer.

sg a scatterlist for SG-capable controllers.

num_sgs number of SG entries

num_mapped_sgs number of SG entries mapped to DMA (internal)

stream_id The stream id, when USB3.0 bulk streams are being used

is_last Indicates if this is the last request of a stream_id before switching to a different stream (required for DWC3 controllers).

no_interrupt If true, hints that no completion irq is needed. Helpful sometimes with deep request queues that are handled directly by DMA controllers.

zero If true, when writing data, makes the last packet be "short" by adding a zero length packet as needed;

short_not_ok When reading data, makes short packets be treated as errors (queue stops advancing till cleanup).

dma_mapped Indicates if request has been mapped to DMA (internal)

complete Function called when request completes, so this request and its buffer may be re-used. The function will always be called with interrupts disabled, and it must not sleep. Reads terminate with a short packet, or when the buffer fills, whichever comes first. When writes terminate, some data bytes will usually still be in flight (often in a hardware fifo). Errors (for reads or writes) stop the queue from advancing until the completion function returns, so that any transfers invalidated by the error may first be dequeued.

context For use by the completion callback

list For use by the gadget driver.

frame_number Reports the interval number in (micro)frame in which the isochronous transfer was transmitted or received.

status Reports completion code, zero or a negative errno. Normally, faults block the transfer queue from advancing until the completion callback returns. Code "-ESHUTDOWN" indicates completion caused by device disconnect, or when the driver disabled the endpoint.

actual Reports bytes transferred to/from the buffer. For reads (OUT transfers) this may be less than the requested length. If the short_not_ok flag is set, short reads are treated as errors even when status otherwise indicates successful completion. Note that for writes (IN transfers) some data bytes may still reside in a device-side FIFO when the request is reported as complete.

Description

These are allocated/freed through the endpoint they're used with. The hardware's driver can add extra per-request data to the memory it returns, which often avoids separate memory allocations (potential failures), later when the request is queued.

Request flags affect request handling, such as whether a zero length packet is written (the "zero" flag), whether a short read should be treated as an error (blocking request queue advance, the "short_not_ok" flag), or hinting that an interrupt is not required (the "no_interrupt" flag, for use with deep request queues).

Bulk endpoints can use any size buffers, and can also be used for interrupt transfers. interrupt-only endpoints can be much less functional.

NOTE

this is analogous to ‘struct urb’ on the host side, except that it’s thinner and promotes more pre-allocation.

struct **usb_ep_caps**
endpoint capabilities description

Definition

```
struct usb_ep_caps {
  unsigned type_control:1;
  unsigned type_iso:1;
  unsigned type_bulk:1;
  unsigned type_int:1;
  unsigned dir_in:1;
  unsigned dir_out:1;
};
```

Members

type_control Endpoint supports control type (reserved for ep0).

type_iso Endpoint supports isochronous transfers.

type_bulk Endpoint supports bulk transfers.

type_int Endpoint supports interrupt transfers.

dir_in Endpoint supports IN direction.

dir_out Endpoint supports OUT direction.

struct **usb_ep**
device side representation of USB endpoint

Definition

```
struct usb_ep {
  void *driver_data;
  const char               *name;
  const struct usb_ep_ops *ops;
  struct list_head         ep_list;
  struct usb_ep_caps       caps;
  bool claimed;
  bool enabled;
  unsigned maxpacket:16;
  unsigned maxpacket_limit:16;
  unsigned max_streams:16;
  unsigned mult:2;
  unsigned maxburst:5;
  u8 address;
  const struct usb_endpoint_descriptor    *desc;
  const struct usb_ss_ep_comp_descriptor  *comp_desc;
};
```

Members

driver_data for use by the gadget driver.

name identifier for the endpoint, such as “ep-a” or “ep9in-bulk”

ops Function pointers used to access hardware-specific operations.

ep_list the gadget’s ep_list holds all of its endpoints

caps The structure describing types and directions supported by endoint.

claimed True if this endpoint is claimed by a function.

enabled The current endpoint enabled/disabled state.

maxpacket The maximum packet size used on this endpoint. The initial value can sometimes be reduced (hardware allowing), according to the endpoint descriptor used to configure the endpoint.

maxpacket_limit The maximum packet size value which can be handled by this endpoint. It’s set once by UDC driver when endpoint is initialized, and should not be changed. Should not be confused with maxpacket.

max_streams The maximum number of streams supported by this EP (0 - 16, actual number is 2^n)

mult multiplier, ‘mult’ value for SS Isoc EPs

maxburst the maximum number of bursts supported by this EP (for usb3)

address used to identify the endpoint when finding descriptor that matches connection speed

desc endpoint descriptor. This pointer is set before the endpoint is enabled and remains valid until the endpoint is disabled.

comp_desc In case of SuperSpeed support, this is the endpoint companion descriptor that is used to configure the endpoint

Description

the bus controller driver lists all the general purpose endpoints in gadget->ep_list. the control endpoint (gadget->ep0) is not in that list, and is accessed only in response to a driver setup() callback.

struct **usb_gadget**
represents a usb slave device

Definition

```
struct usb_gadget {
  struct work_struct              work;
  struct usb_udc                  *udc;
  const struct usb_gadget_ops     *ops;
  struct usb_ep                   *ep0;
  struct list_head                ep_list;
  enum usb_device_speed           speed;
  enum usb_device_speed           max_speed;
  enum usb_device_state           state;
  const char                      *name;
  struct device                   dev;
  unsigned isoch_delay;
```

(continues on next page)

(continued from previous page)

```
  unsigned out_epnum;
  unsigned in_epnum;
  unsigned mA;
  struct usb_otg_caps             *otg_caps;
  unsigned sg_supported:1;
  unsigned is_otg:1;
  unsigned is_a_peripheral:1;
  unsigned b_hnp_enable:1;
  unsigned a_hnp_support:1;
  unsigned a_alt_hnp_support:1;
  unsigned hnp_polling_support:1;
  unsigned host_request_flag:1;
  unsigned quirk_ep_out_aligned_size:1;
  unsigned quirk_altset_not_supp:1;
  unsigned quirk_stall_not_supp:1;
  unsigned quirk_zlp_not_supp:1;
  unsigned quirk_avoids_skb_reserve:1;
  unsigned is_selfpowered:1;
  unsigned deactivated:1;
  unsigned connected:1;
  unsigned lpm_capable:1;
  int irq;
};
```

Members

work (internal use) Workqueue to be used for sysfs_notify()

udc struct usb_udc pointer for this gadget

ops Function pointers used to access hardware-specific operations.

ep0 Endpoint zero, used when reading or writing responses to driver setup() requests

ep_list List of other endpoints supported by the device.

speed Speed of current connection to USB host.

max_speed Maximal speed the UDC can handle. UDC must support this and all slower speeds.

state the state we are now (attached, suspended, configured, etc)

name Identifies the controller hardware type. Used in diagnostics and sometimes configuration.

dev Driver model state for this abstract device.

isoch_delay value from Set Isoch Delay request. Only valid on SS/SSP

out_epnum last used out ep number

in_epnum last used in ep number

mA last set mA value

otg_caps OTG capabilities of this gadget.

sg_supported true if we can handle scatter-gather

is_otg True if the USB device port uses a Mini-AB jack, so that the gadget driver must provide a USB OTG descriptor.

is_a_peripheral False unless is_otg, the "A" end of a USB cable is in the Mini-AB jack, and HNP has been used to switch roles so that the "A" device currently acts as A-Peripheral, not A-Host.

b_hnp_enable OTG device feature flag, indicating that the A-Host enabled HNP support.

a_hnp_support OTG device feature flag, indicating that the A-Host supports HNP at this port.

a_alt_hnp_support OTG device feature flag, indicating that the A-Host only supports HNP on a different root port.

hnp_polling_support OTG device feature flag, indicating if the OTG device in peripheral mode can support HNP polling.

host_request_flag OTG device feature flag, indicating if A-Peripheral or B-Peripheral wants to take host role.

quirk_ep_out_aligned_size epout requires buffer size to be aligned to MaxPacketSize.

quirk_altset_not_supp UDC controller doesn't support alt settings.

quirk_stall_not_supp UDC controller doesn't support stalling.

quirk_zlp_not_supp UDC controller doesn't support ZLP.

quirk_avoids_skb_reserve udc/platform wants to avoid skb_reserve() in u_ether.c to improve performance.

is_selfpowered if the gadget is self-powered.

deactivated True if gadget is deactivated - in deactivated state it cannot be connected.

connected True if gadget is connected.

lpm_capable If the gadget max_speed is FULL or HIGH, this flag indicates that it supports LPM as per the LPM ECN & errata.

irq the interrupt number for device controller.

Description

Gadgets have a mostly-portable "gadget driver" implementing device functions, handling all usb configurations and interfaces. Gadget drivers talk to hardware-specific code indirectly, through ops vectors. That insulates the gadget driver from hardware details, and packages the hardware endpoints through generic i/o queues. The "usb_gadget" and "usb_ep" interfaces provide that insulation from the hardware.

Except for the driver data, all fields in this structure are read-only to the gadget driver. That driver data is part of the "driver model" infrastructure in 2.6 (and later) kernels, and for earlier systems is grouped in a similar structure that's not known to the rest of the kernel.

Values of the three OTG device feature flags are updated before the setup() call corresponding to USB_REQ_SET_CONFIGURATION, and before driver suspend() calls. They are valid only when is_otg, and when the device is acting as a B-Peripheral (so is_a_peripheral is false).

size_t **usb_ep_align**(struct usb_ep * ep, size_t len)
returns **len** aligned to ep's maxpacketsize.

Parameters

struct usb_ep * ep the endpoint whose maxpacketsize is used to align **len**

size_t len buffer size's length to align to **ep**'s maxpacketsize

Description

This helper is used to align buffer's size to an ep's maxpacketsize.

size_t **usb_ep_align_maybe**(struct usb_gadget * g, struct usb_ep * ep, size_t len)
returns **len** aligned to ep's maxpacketsize if gadget requires quirk_ep_out_aligned_size, otherwise returns len.

Parameters

struct usb_gadget * g controller to check for quirk

struct usb_ep * ep the endpoint whose maxpacketsize is used to align **len**

size_t len buffer size's length to align to **ep**'s maxpacketsize

Description

This helper is used in case it's required for any reason to check and maybe align buffer's size to an ep's maxpacketsize.

int **gadget_is_altset_supported**(struct usb_gadget * g)
return true iff the hardware supports altsettings

Parameters

struct usb_gadget * g controller to check for quirk

int **gadget_is_stall_supported**(struct usb_gadget * g)
return true iff the hardware supports stalling

Parameters

struct usb_gadget * g controller to check for quirk

int **gadget_is_zlp_supported**(struct usb_gadget * g)
return true iff the hardware supports zlp

Parameters

struct usb_gadget * g controller to check for quirk

int **gadget_avoids_skb_reserve**(struct usb_gadget * g)
return true iff the hardware would like to avoid skb_reserve to improve performance.

Parameters

struct usb_gadget * g controller to check for quirk

int **gadget_is_dualspeed**(struct usb_gadget * g)
return true iff the hardware handles high speed

Parameters

struct usb_gadget * g controller that might support both high and full speeds

int **gadget_is_superspeed**(struct usb_gadget * g)
return true if the hardware handles superspeed

Parameters

struct usb_gadget * g controller that might support superspeed

int **gadget_is_superspeed_plus**(struct usb_gadget * g)
return true if the hardware handles superspeed plus

Parameters

struct usb_gadget * g controller that might support superspeed plus

int **gadget_is_otg**(struct usb_gadget * g)
return true iff the hardware is OTG-ready

Parameters

struct usb_gadget * g controller that might have a Mini-AB connector

Description

This is a runtime test, since kernels with a USB-OTG stack sometimes run on boards which only have a Mini-B (or Mini-A) connector.

struct **usb_gadget_driver**
driver for usb 'slave' devices

Definition

```
struct usb_gadget_driver {
  char *function;
  enum usb_device_speed   max_speed;
  int (*bind)(struct usb_gadget *gadget, struct usb_gadget_driver *driver);
  void (*unbind)(struct usb_gadget *);
  int (*setup)(struct usb_gadget *, const struct usb_ctrlrequest *);
  void (*disconnect)(struct usb_gadget *);
  void (*suspend)(struct usb_gadget *);
  void (*resume)(struct usb_gadget *);
  void (*reset)(struct usb_gadget *);
  struct device_driver    driver;
  char *udc_name;
  struct list_head        pending;
  unsigned match_existing_only:1;
};
```

Members

function String describing the gadget's function

max_speed Highest speed the driver handles.

bind the driver's bind callback

unbind Invoked when the driver is unbound from a gadget, usually from rmmod (after a disconnect is reported). Called in a context that permits sleeping.

setup Invoked for ep0 control requests that aren't handled by the hardware level driver. Most calls must be handled by the gadget driver, including descriptor and configuration management. The 16 bit members of the setup data are in USB byte order. Called in_interrupt; this may not sleep. Driver queues a response to ep0, or returns negative to stall.

disconnect Invoked after all transfers have been stopped, when the host is disconnected. May be called in_interrupt; this may not sleep. Some devices can't detect disconnect, so this might not be called except as part of controller shutdown.

suspend Invoked on USB suspend. May be called in_interrupt.

resume Invoked on USB resume. May be called in_interrupt.

reset Invoked on USB bus reset. It is mandatory for all gadget drivers and should be called in_interrupt.

driver Driver model state for this driver.

udc_name A name of UDC this driver should be bound to. If udc_name is NULL, this driver will be bound to any available UDC.

pending UDC core private data used for deferred probe of this driver.

match_existing_only If udc is not found, return an error and don't add this gadget driver to list of pending driver

Description

Devices are disabled till a gadget driver successfully bind()s, which means the driver will handle setup() requests needed to enumerate (and meet "chapter 9" requirements) then do some useful work.

If gadget->is_otg is true, the gadget driver must provide an OTG descriptor during enumeration, or else fail the bind() call. In such cases, no USB traffic may flow until both bind() returns without having called usb_gadget_disconnect(), and the USB host stack has initialized.

Drivers use hardware-specific knowledge to configure the usb hardware. endpoint addressing is only one of several hardware characteristics that are in descriptors the ep0 implementation returns from setup() calls.

Except for ep0 implementation, most driver code shouldn't need change to run on top of different usb controllers. It'll use endpoints set up by that ep0 implementation.

The usb controller driver handles a few standard usb requests. Those include set_address, and feature flags for devices, interfaces, and endpoints (the get_status, set_feature, and clear_feature requests).

Accordingly, the driver's setup() callback must always implement all get_descriptor requests, returning at least a device descriptor and a configuration descriptor. Drivers must make sure the endpoint descriptors match any hardware constraints. Some hardware also constrains other descriptors. (The pxa250 allows only configurations 1, 2, or 3).

The driver's setup() callback must also implement set_configuration, and should also implement set_interface, get_configuration, and get_interface. Setting a configuration (or interface) is where endpoints should be activated or (config 0) shut down.

(Note that only the default control endpoint is supported. Neither hosts nor devices generally support control traffic except to ep0.)

Most devices will ignore USB suspend/resume operations, and so will not provide those callbacks. However, some may need to change modes when the host is not longer directing those activities. For example, local controls (buttons, dials, etc) may need to be re-enabled since the (remote) host can't do that any longer; or an error state might be cleared, to make the device behave identically whether or not power is maintained.

int **usb_gadget_probe_driver**(struct usb_gadget_driver * driver)
probe a gadget driver

Parameters

struct usb_gadget_driver * driver the driver being registered

Context

can sleep

Description

Call this in your gadget driver's module initialization function, to tell the underlying usb controller driver about your driver. The **bind()** function will be called to bind it to a gadget before this registration call returns. It's expected that the **bind()** function will be in init sections.

int **usb_gadget_unregister_driver**(struct usb_gadget_driver * driver)
unregister a gadget driver

Parameters

struct usb_gadget_driver * driver the driver being unregistered

Context

can sleep

Description

Call this in your gadget driver's module cleanup function, to tell the underlying usb controller that your driver is going away. If the controller is connected to a USB host, it will first disconnect(). The driver is also requested to unbind() and clean up any device state, before this procedure finally returns. It's expected that the unbind() functions will in in exit sections, so may not be linked in some kernels.

struct **usb_string**
wraps a C string and its USB id

Definition

```
struct usb_string {
  u8 id;
  const char              *s;
};
```

Members

id the (nonzero) ID for this string

s the string, in UTF-8 encoding

Description

If you're using `usb_gadget_get_string()`, use this to wrap a string together with its ID.

struct **usb_gadget_strings**
a set of USB strings in a given language

Definition

```
struct usb_gadget_strings {
  u16 language;
  struct usb_string       *strings;
};
```

Members

language identifies the strings' language (0x0409 for en-us)

strings array of strings with their ids

Description

If you're using `usb_gadget_get_string()`, use this to wrap all the strings for a given language.

void **usb_free_descriptors**(struct usb_descriptor_header ** v)
free descriptors returned by `usb_copy_descriptors()`

Parameters

struct usb_descriptor_header ** v vector of descriptors

Optional Utilities

The core API is sufficient for writing a USB Gadget Driver, but some optional utilities are provided to simplify common tasks. These utilities include endpoint autoconfiguration.

int **usb_gadget_get_string**(const struct usb_gadget_strings * table, int id, u8 * buf)
fill out a string descriptor

Parameters

const struct usb_gadget_strings * table of c strings encoded using UTF-8

int id string id, from low byte of wValue in get string descriptor

u8 * buf at least 256 bytes, must be 16-bit aligned

Description

Finds the UTF-8 string matching the ID, and converts it into a string descriptor in utf16-le. Returns length of descriptor (always even) or negative errno

If your driver needs stings in multiple languages, you'll probably "switch (wIndex) { ···}" in your ep0 string descriptor logic, using this routine after choosing which set of UTF-8 strings to use. Note that US-ASCII is a strict subset of UTF-8; any string bytes with the eighth bit set will be multibyte UTF-8 characters, not ISO-8859/1 characters (which are also widely used in C strings).

bool **usb_validate_langid**(u16 langid)
validate usb language identifiers

Parameters

u16 langid undescribed

Description

Returns true for valid language identifier, otherwise false.

int **usb_descriptor_fillbuf**(void * buf, unsigned buflen, const struct usb_descriptor_header ** src)
fill buffer with descriptors

Parameters

void * buf Buffer to be filled

unsigned buflen Size of buf

const struct usb_descriptor_header ** src Array of descriptor pointers, terminated by null pointer.

Description

Copies descriptors into the buffer, returning the length or a negative error code if they can't all be copied. Useful when assembling descriptors for an associated set of interfaces used as part of configuring a composite device; or in other cases where sets of descriptors need to be marshaled.

int **usb_gadget_config_buf**(const struct usb_config_descriptor * config, void * buf, unsigned length, const struct usb_descriptor_header ** desc)
builts a complete configuration descriptor

Parameters

const struct usb_config_descriptor * config Header for the descriptor, including characteristics such as power requirements and number of interfaces.

void * buf Buffer for the resulting configuration descriptor.

unsigned length Length of buffer. If this is not big enough to hold the entire configuration descriptor, an error code will be returned.

const struct usb_descriptor_header ** desc Null-terminated vector of pointers to the descriptors (interface, endpoint, etc) defining all functions in this device configuration.

Description

This copies descriptors into the response buffer, building a descriptor for that configuration. It returns the buffer length or a negative status code. The config.wTotalLength field is set to match the length of the result, but other descriptor fields (including power usage and interface count) must be set by the caller.

Gadget drivers could use this when constructing a config descriptor in response to USB_REQ_GET_DESCRIPTOR. They will need to patch the resulting bDescriptorType value if USB_DT_OTHER_SPEED_CONFIG is needed.

struct usb_descriptor_header ** **usb_copy_descriptors**(struct usb_descriptor_header ** src)

copy a vector of USB descriptors

Parameters

struct usb_descriptor_header ** src null-terminated vector to copy

Context

initialization code, which may sleep

Description

This makes a copy of a vector of USB descriptors. Its primary use is to support usb_function objects which can have multiple copies, each needing different descriptors. Functions may have static tables of descriptors, which are used as templates and customized with identifiers (for interfaces, strings, endpoints, and more) as needed by a given function instance.

Composite Device Framework

The core API is sufficient for writing drivers for composite USB devices (with more than one function in a given configuration), and also multi-configuration devices (also more than one function, but not necessarily sharing a given configuration). There is however an optional framework which makes it easier to reuse and combine functions.

Devices using this framework provide a struct `usb_composite_driver`, which in turn provides one or more struct `usb_configuration` instances. Each such configuration includes at least one struct `usb_function`, which packages a user visible role such as “network link” or “mass storage device”. Management functions may also exist, such as “Device Firmware Upgrade”.

struct **usb_os_desc_ext_prop**

describes one “Extended Property”

Definition

```
struct usb_os_desc_ext_prop {
  struct list_head        entry;
```

(continues on next page)

(continued from previous page)

```
  u8 type;
  int name_len;
  char *name;
  int data_len;
  char *data;
  struct config_item      item;
};
```

Members

entry used to keep a list of extended properties

type Extended Property type

name_len Extended Property unicode name length, including terminating '0'

name Extended Property name

data_len Length of Extended Property blob (for unicode store double len)

data Extended Property blob

item Represents this Extended Property in configfs

struct **usb_os_desc**
describes OS descriptors associated with one interface

Definition

```
struct usb_os_desc {
  char *ext_compat_id;
  struct list_head        ext_prop;
  int ext_prop_len;
  int ext_prop_count;
  struct mutex            *opts_mutex;
  struct config_group     group;
  struct module           *owner;
};
```

Members

ext_compat_id 16 bytes of "Compatible ID" and "Subcompatible ID"

ext_prop Extended Properties list

ext_prop_len Total length of Extended Properties blobs

ext_prop_count Number of Extended Properties

opts_mutex Optional mutex protecting config data of a usb_function_instance

group Represents OS descriptors associated with an interface in configfs

owner Module associated with this OS descriptor

struct **usb_os_desc_table**
describes OS descriptors associated with one interface of a usb_function

Definition

```
struct usb_os_desc_table {
  int if_id;
  struct usb_os_desc      *os_desc;
};
```

Members

if_id Interface id

os_desc “Extended Compatibility ID” and “Extended Properties” of the interface

Description

Each interface can have at most one “Extended Compatibility ID” and a number of “Extended Properties”.

struct **usb_function**
describes one function of a configuration

Definition

```
struct usb_function {
  const char                      *name;
  struct usb_gadget_strings       **strings;
  struct usb_descriptor_header    **fs_descriptors;
  struct usb_descriptor_header    **hs_descriptors;
  struct usb_descriptor_header    **ss_descriptors;
  struct usb_descriptor_header    **ssp_descriptors;
  struct usb_configuration        *config;
  struct usb_os_desc_table        *os_desc_table;
  unsigned os_desc_n;
  int (*bind)(struct usb_configuration *, struct usb_function *);
  void (*unbind)(struct usb_configuration *, struct usb_function *);
  void (*free_func)(struct usb_function *f);
  struct module           *mod;
  int (*set_alt)(struct usb_function *, unsigned interface, unsigned alt);
  int (*get_alt)(struct usb_function *, unsigned interface);
  void (*disable)(struct usb_function *);
  int (*setup)(struct usb_function *, const struct usb_ctrlrequest *);
  bool (*req_match)(struct usb_function *,const struct usb_ctrlrequest *,␣
↪bool config0);
  void (*suspend)(struct usb_function *);
  void (*resume)(struct usb_function *);
  int (*get_status)(struct usb_function *);
  int (*func_suspend)(struct usb_function *, u8 suspend_opt);
};
```

Members

name For diagnostics, identifies the function.

strings tables of strings, keyed by identifiers assigned during bind() and by language IDs provided in control requests

fs_descriptors Table of full (or low) speed descriptors, using interface and string identifiers assigned during **bind()**. If this pointer is null, the function will not be available at full speed (or at low speed).

hs_descriptors Table of high speed descriptors, using interface and string identifiers assigned during **bind()**. If this pointer is null, the function will not be available at high speed.

ss_descriptors Table of super speed descriptors, using interface and string identifiers assigned during **bind()**. If this pointer is null after initiation, the function will not be available at super speed.

ssp_descriptors Table of super speed plus descriptors, using interface and string identifiers assigned during **bind()**. If this pointer is null after initiation, the function will not be available at super speed plus.

config assigned when **usb_add_function()** is called; this is the configuration with which this function is associated.

os_desc_table Table of (interface id, os descriptors) pairs. The function can expose more than one interface. If an interface is a member of an IAD, only the first interface of IAD has its entry in the table.

os_desc_n Number of entries in os_desc_table

bind Before the gadget can register, all of its functions bind() to the available resources including string and interface identifiers used in interface or class descriptors; endpoints; I/O buffers; and so on.

unbind Reverses **bind**; called as a side effect of unregistering the driver which added this function.

free_func free the struct usb_function.

mod (internal) points to the module that created this structure.

set_alt (REQUIRED) Reconfigures altsettings; function drivers may initialize usb_ep.driver data at this time (when it is used). Note that setting an interface to its current altsetting resets interface state, and that all interfaces have a disabled state.

get_alt Returns the active altsetting. If this is not provided, then only altsetting zero is supported.

disable (REQUIRED) Indicates the function should be disabled. Reasons include host resetting or reconfiguring the gadget, and disconnection.

setup Used for interface-specific control requests.

req_match Tests if a given class request can be handled by this function.

suspend Notifies functions when the host stops sending USB traffic.

resume Notifies functions when the host restarts USB traffic.

get_status Returns function status as a reply to GetStatus() request when the recipient is Interface.

func_suspend callback to be called when SetFeature(FUNCTION_SUSPEND) is reseived

Description

A single USB function uses one or more interfaces, and should in most cases support operation at both full and high speeds. Each function is associated by

usb_add_function() with a one configuration; that function causes **bind()** to be called so resources can be allocated as part of setting up a gadget driver. Those resources include endpoints, which should be allocated using **usb_ep_autoconfig()**.

To support dual speed operation, a function driver provides descriptors for both high and full speed operation. Except in rare cases that don't involve bulk endpoints, each speed needs different endpoint descriptors.

Function drivers choose their own strategies for managing instance data. The simplest strategy just declares it "static", which means the function can only be activated once. If the function needs to be exposed in more than one configuration at a given speed, it needs to support multiple usb_function structures (one for each configuration).

A more complex strategy might encapsulate a **usb_function** structure inside a driver-specific instance structure to allows multiple activations. An example of multiple activations might be a CDC ACM function that supports two or more distinct instances within the same configuration, providing several independent logical data links to a USB host.

struct **usb_configuration**
represents one gadget configuration

Definition

```
struct usb_configuration {
  const char                    *label;
  struct usb_gadget_strings     **strings;
  const struct usb_descriptor_header **descriptors;
  void (*unbind)(struct usb_configuration *);
  int (*setup)(struct usb_configuration *, const struct usb_ctrlrequest *);
  u8 bConfigurationValue;
  u8 iConfiguration;
  u8 bmAttributes;
  u16 MaxPower;
  struct usb_composite_dev      *cdev;
};
```

Members

label For diagnostics, describes the configuration.

strings Tables of strings, keyed by identifiers assigned during **bind()** and by language IDs provided in control requests.

descriptors Table of descriptors preceding all function descriptors. Examples include OTG and vendor-specific descriptors.

unbind Reverses **bind**; called as a side effect of unregistering the driver which added this configuration.

setup Used to delegate control requests that aren't handled by standard device infrastructure or directed at a specific interface.

bConfigurationValue Copied into configuration descriptor.

iConfiguration Copied into configuration descriptor.

bmAttributes Copied into configuration descriptor.

MaxPower Power consumtion in mA. Used to compute bMaxPower in the configuration descriptor after considering the bus speed.

cdev assigned by **usb_add_config()** before calling **bind()**; this is the device associated with this configuration.

Description

Configurations are building blocks for gadget drivers structured around function drivers. Simple USB gadgets require only one function and one configuration, and handle dual-speed hardware by always providing the same functionality. Slightly more complex gadgets may have more than one single-function configuration at a given speed; or have configurations that only work at one speed.

Composite devices are, by definition, ones with configurations which include more than one function.

The lifecycle of a usb_configuration includes allocation, initialization of the fields described above, and calling **usb_add_config()** to set up internal data and bind it to a specific device. The configuration's **bind()** method is then used to initialize all the functions and then call **usb_add_function()** for them.

Those functions would normally be independent of each other, but that's not mandatory. CDC WMC devices are an example where functions often depend on other functions, with some functions subsidiary to others. Such interdependency may be managed in any way, so long as all of the descriptors complete by the time the composite driver returns from its bind() routine.

struct **usb_composite_driver**
groups configurations into a gadget

Definition

```
struct usb_composite_driver {
  const char                              *name;
  const struct usb_device_descriptor      *dev;
  struct usb_gadget_strings               **strings;
  enum usb_device_speed                   max_speed;
  unsigned needs_serial:1;
  int (*bind)(struct usb_composite_dev *cdev);
  int (*unbind)(struct usb_composite_dev *);
  void (*disconnect)(struct usb_composite_dev *);
  void (*suspend)(struct usb_composite_dev *);
  void (*resume)(struct usb_composite_dev *);
  struct usb_gadget_driver                gadget_driver;
};
```

Members

name For diagnostics, identifies the driver.

dev Template descriptor for the device, including default device identifiers.

strings tables of strings, keyed by identifiers assigned during **bind** and language IDs provided in control requests. Note: The first entries are predefined. The first entry that may be used is USB_GADGET_FIRST_AVAIL_IDX

max_speed Highest speed the driver supports.

needs_serial set to 1 if the gadget needs userspace to provide a serial number. If one is not provided, warning will be printed.

bind (REQUIRED) Used to allocate resources that are shared across the whole device, such as string IDs, and add its configurations using **usb_add_config()**. This may fail by returning a negative errno value; it should return zero on successful initialization.

unbind Reverses **bind**; called as a side effect of unregistering this driver.

disconnect optional driver disconnect method

suspend Notifies when the host stops sending USB traffic, after function notifications

resume Notifies configuration when the host restarts USB traffic, before function notifications

gadget_driver Gadget driver controlling this driver

Description

Devices default to reporting self powered operation. Devices which rely on bus powered operation should report this in their **bind** method.

Before returning from **bind**, various fields in the template descriptor may be overridden. These include the idVendor/idProduct/bcdDevice values normally to bind the appropriate host side driver, and the three strings (iManufacturer, iProduct, iSerialNumber) normally used to provide user meaningful device identifiers. (The strings will not be defined unless they are defined in **dev** and **strings**.) The correct ep0 maxpacket size is also reported, as defined by the underlying controller driver.

module_usb_composite_driver(__usb_composite_driver)
Helper macro for registering a USB gadget composite driver

Parameters

__usb_composite_driver usb_composite_driver struct

Description

Helper macro for USB gadget composite drivers which do not do anything special in module init/exit. This eliminates a lot of boilerplate. Each module may only use this macro once, and calling it replaces `module_init()` and `module_exit()`

struct **usb_composite_dev**
represents one composite usb gadget

Definition

```
struct usb_composite_dev {
  struct usb_gadget               *gadget;
  struct usb_request              *req;
  struct usb_request              *os_desc_req;
  struct usb_configuration        *config;
  u8 qw_sign[OS_STRING_QW_SIGN_LEN];
  u8 b_vendor_code;
  struct usb_configuration        *os_desc_config;
  unsigned int                    use_os_string:1;
```

(continues on next page)

(continued from previous page)

```
  unsigned int                    setup_pending:1;
  unsigned int                    os_desc_pending:1;
};
```

Members

gadget read-only, abstracts the gadget's usb peripheral controller

req used for control responses; buffer is pre-allocated

os_desc_req used for OS descriptors responses; buffer is pre-allocated

config the currently active configuration

qw_sign qwSignature part of the OS string

b_vendor_code bMS_VendorCode part of the OS string

os_desc_config the configuration to be used with OS descriptors

use_os_string false by default, interested gadgets set it

setup_pending true when setup request is queued but not completed

os_desc_pending true when os_desc request is queued but not completed

Description

One of these devices is allocated and initialized before the associated device driver's bind() is called.

OPEN ISSUE: it appears that some WUSB devices will need to be built by combining a normal (wired) gadget with a wireless one. This revision of the gadget framework should probably try to make sure doing that won't hurt too much.

One notion for how to handle Wireless USB devices involves:

(a) a second gadget here, discovery mechanism TBD, but likely needing separate "register/unregister WUSB gadget" calls;

(b) updates to usb_gadget to include flags "is it wireless", "is it wired", plus (presumably in a wrapper structure) bandgroup and PHY info;

(c) presumably a wireless_ep wrapping a usb_ep, and reporting wireless-specific parameters like maxburst and maxsequence;

(d) configurations that are specific to wireless links;

(e) function drivers that understand wireless configs and will support wireless for (additional) function instances;

(f) a function to support association setup (like CBAF), not necessarily requiring a wireless adapter;

(g) composite device setup that can create one or more wireless configs, including appropriate association setup support;

(h) more, TBD.

int **config_ep_by_speed_and_alt**(struct usb_gadget * g, struct usb_function * f, struct usb_ep * _ep, u8 alt)
configures the given endpoint according to gadget speed.

Parameters

struct usb_gadget * g pointer to the gadget

struct usb_function * f usb function

struct usb_ep * _ep the endpoint to configure

u8 alt alternate setting number

Return

error code, 0 on success

Description

This function chooses the right descriptors for a given endpoint according to gadget speed and saves it in the endpoint desc field. If the endpoint already has a descriptor assigned to it - overwrites it with currently corresponding descriptor. The endpoint maxpacket field is updated according to the chosen descriptor.

Note

the supplied function should hold all the descriptors for supported speeds

int **config_ep_by_speed**(struct usb_gadget * g, struct usb_function * f, struct usb_ep * _ep)
configures the given endpoint according to gadget speed.

Parameters

struct usb_gadget * g pointer to the gadget

struct usb_function * f usb function

struct usb_ep * _ep the endpoint to configure

Return

error code, 0 on success

Description

This function chooses the right descriptors for a given endpoint according to gadget speed and saves it in the endpoint desc field. If the endpoint already has a descriptor assigned to it - overwrites it with currently corresponding descriptor. The endpoint maxpacket field is updated according to the chosen descriptor.

Note

the supplied function should hold all the descriptors for supported speeds

int **usb_add_function**(struct usb_configuration * config, struct usb_function * function)
add a function to a configuration

Parameters

struct usb_configuration * config the configuration

struct usb_function * function the function being added

Context

single threaded during gadget setup

Description

After initialization, each configuration must have one or more functions added to it. Adding a function involves calling its **bind()** method to allocate resources such as interface and string identifiers and endpoints.

This function returns the value of the function's bind(), which is zero for success else a negative errno value.

int **usb_function_deactivate**(struct usb_function * function)
prevent function and gadget enumeration

Parameters

struct usb_function * function the function that isn't yet ready to respond

Description

Blocks response of the gadget driver to host enumeration by preventing the data line pullup from being activated. This is normally called during **bind()** processing to change from the initial "ready to respond" state, or when a required resource becomes available.

For example, drivers that serve as a passthrough to a userspace daemon can block enumeration unless that daemon (such as an OBEX, MTP, or print server) is ready to handle host requests.

Not all systems support software control of their USB peripheral data pullups.

Returns zero on success, else negative errno.

int **usb_function_activate**(struct usb_function * function)
allow function and gadget enumeration

Parameters

struct usb_function * function function on which `usb_function_activate()` was called

Description

Reverses effect of `usb_function_deactivate()`. If no more functions are delaying their activation, the gadget driver will respond to host enumeration procedures.

Returns zero on success, else negative errno.

int **usb_interface_id**(struct usb_configuration * config, struct usb_function * function)
allocate an unused interface ID

Parameters

struct usb_configuration * config configuration associated with the interface

struct usb_function * function function handling the interface

Context

single threaded during gadget setup

Description

`usb_interface_id()` is called from usb_function.bind() callbacks to allocate new interface IDs. The function driver will then store that ID in interface, association, CDC union, and other descriptors. It will also handle any control requests targeted at that interface, particularly changing its altsetting via set_alt(). There may also be class-specific or vendor-specific requests to handle.

All interface identifier should be allocated using this routine, to ensure that for example different functions don't wrongly assign different meanings to the same identifier. Note that since interface identifiers are configuration-specific, functions used in more than one configuration (or more than once in a given configuration) need multiple versions of the relevant descriptors.

Returns the interface ID which was allocated; or -ENODEV if no more interface IDs can be allocated.

int **usb_add_config**(struct usb_composite_dev * cdev, struct usb_configuration * config, int (*bind)(struct usb_configuration *))
add a configuration to a device.

Parameters

struct usb_composite_dev * cdev wraps the USB gadget

struct usb_configuration * config the configuration, with bConfigurationValue assigned

int (*)(struct usb_configuration *) bind the configuration's bind function

Context

single threaded during gadget setup

Description

One of the main tasks of a composite **bind()** routine is to add each of the configurations it supports, using this routine.

This function returns the value of the configuration's **bind()**, which is zero for success else a negative errno value. Binding configurations assigns global resources including string IDs, and per-configuration resources such as interface IDs and endpoints.

int **usb_string_id**(struct usb_composite_dev * cdev)
allocate an unused string ID

Parameters

struct usb_composite_dev * cdev the device whose string descriptor IDs are being allocated

Context

single threaded during gadget setup

Description

usb_string_id() is called from bind() callbacks to allocate string IDs. Drivers for functions, configurations, or gadgets will then store that ID in the appropriate descriptors and string table.

All string identifier should be allocated using this, **usb_string_ids_tab()** or **usb_string_ids_n()** routine, to ensure that for example different functions don' t wrongly assign different meanings to the same identifier.

int **usb_string_ids_tab**(struct usb_composite_dev * cdev, struct usb_string * str)
allocate unused string IDs in batch

Parameters

struct usb_composite_dev * cdev the device whose string descriptor IDs are being allocated

struct usb_string * str an array of usb_string objects to assign numbers to

Context

single threaded during gadget setup

Description

usb_string_ids() is called from bind() callbacks to allocate string IDs. Drivers for functions, configurations, or gadgets will then copy IDs from the string table to the appropriate descriptors and string table for other languages.

All string identifier should be allocated using this, **usb_string_id()** or **usb_string_ids_n()** routine, to ensure that for example different functions don' t wrongly assign different meanings to the same identifier.

struct usb_string * **usb_gstrings_attach**(struct usb_composite_dev * cdev, struct usb_gadget_strings ** sp, unsigned n_strings)
attach gadget strings to a cdev and assign ids

Parameters

struct usb_composite_dev * cdev the device whose string descriptor IDs are being allocated and attached.

struct usb_gadget_strings ** sp an array of usb_gadget_strings to attach.

unsigned n_strings number of entries in each usb_strings array (sp[]->strings)

Description

This function will create a deep copy of usb_gadget_strings and usb_string and attach it to the cdev. The actual string (usb_string.s) will not be copied but only a referenced will be made. The struct usb_gadget_strings array may contain multiple languages and should be NULL terminated. The ->language pointer of each struct usb_gadget_strings has to contain the same amount of entries. For instance: sp[0] is en-US, sp[1] is es-ES. It is expected that the first usb_string entry of es-ES contains the translation of the first usb_string entry of en-US. Therefore both entries become the same id assign.

int **usb_string_ids_n**(struct usb_composite_dev * c, unsigned n)
allocate unused string IDs in batch

Parameters

struct usb_composite_dev * c the device whose string descriptor IDs are being allocated

unsigned n number of string IDs to allocate

Context

single threaded during gadget setup

Description

Returns the first requested ID. This ID and next **n**-1 IDs are now valid IDs. At least provided that **n** is non-zero because if it is, returns last requested ID which is now very useful information.

usb_string_ids_n() is called from bind() callbacks to allocate string IDs. Drivers for functions, configurations, or gadgets will then store that ID in the appropriate descriptors and string table.

All string identifier should be allocated using this, **usb_string_id()** or **usb_string_ids_n()** routine, to ensure that for example different functions don' t wrongly assign different meanings to the same identifier.

int **usb_composite_probe**(struct usb_composite_driver * driver)
register a composite driver

Parameters

struct usb_composite_driver * driver the driver to register

Context

single threaded during gadget setup

Description

This function is used to register drivers using the composite driver framework. The return value is zero, or a negative errno value. Those values normally come from the driver' s **bind** method, which does all the work of setting up the driver to match the hardware.

On successful return, the gadget is ready to respond to requests from the host, unless one of its components invokes usb_gadget_disconnect() while it was binding. That would usually be done in order to wait for some userspace participation.

void **usb_composite_unregister**(struct usb_composite_driver * driver)
unregister a composite driver

Parameters

struct usb_composite_driver * driver the driver to unregister

Description

This function is used to unregister drivers using the composite driver framework.

void **usb_composite_setup_continue**(struct usb_composite_dev * cdev)
Continue with the control transfer

Parameters

struct usb_composite_dev * cdev the composite device who's control transfer was kept waiting

Description

This function must be called by the USB function driver to continue with the control transfer's data/status stage in case it had requested to delay the data/status stages. A USB function's setup handler (e.g. set_alt()) can request the composite framework to delay the setup request's data/status stages by returning USB_GADGET_DELAYED_STATUS.

Composite Device Functions

At this writing, a few of the current gadget drivers have been converted to this framework. Near-term plans include converting all of them, except for `gadgetfs`.

20.2.4 Peripheral Controller Drivers

The first hardware supporting this API was the NetChip 2280 controller, which supports USB 2.0 high speed and is based on PCI. This is the `net2280` driver module. The driver supports Linux kernel versions 2.4 and 2.6; contact NetChip Technologies for development boards and product information.

Other hardware working in the `gadget` framework includes: Intel's PXA 25x and IXP42x series processors (`pxa2xx_udc`), Toshiba TC86c001 "Goku-S" (`goku_udc`), Renesas SH7705/7727 (`sh_udc`), MediaQ 11xx (`mq11xx_udc`), Hynix HMS30C7202 (`h7202_udc`), National 9303/4 (`n9604_udc`), Texas Instruments OMAP (`omap_udc`), Sharp LH7A40x (`lh7a40x_udc`), and more. Most of those are full speed controllers.

At this writing, there are people at work on drivers in this framework for several other USB device controllers, with plans to make many of them be widely available.

A partial USB simulator, the `dummy_hcd` driver, is available. It can act like a net2280, a pxa25x, or an sa11x0 in terms of available endpoints and device speeds; and it simulates control, bulk, and to some extent interrupt transfers. That lets you develop some parts of a gadget driver on a normal PC, without any special hardware, and perhaps with the assistance of tools such as GDB running with User Mode Linux. At least one person has expressed interest in adapting that approach, hooking it up to a simulator for a microcontroller. Such simulators can help debug subsystems where the runtime hardware is unfriendly to software development, or is not yet available.

Support for other controllers is expected to be developed and contributed over time, as this driver framework evolves.

20.2.5 Gadget Drivers

In addition to Gadget Zero (used primarily for testing and development with drivers for usb controller hardware), other gadget drivers exist.

There's an `ethernet` gadget driver, which implements one of the most useful Communications Device Class (CDC) models. One of the standards for cable modem interoperability even specifies the use of this ethernet model as one of two mandatory options. Gadgets using this code look to a USB host as if they're an Ethernet adapter. It provides access to a network where the gadget's CPU is one host, which could easily be bridging, routing, or firewalling access to other networks. Since some hardware can't fully implement the CDC Ethernet requirements, this driver also implements a "good parts only" subset of CDC Ethernet. (That subset doesn't advertise itself as CDC Ethernet, to avoid creating problems.)

Support for Microsoft's `RNDIS` protocol has been contributed by Pengutronix and Auerswald GmbH. This is like CDC Ethernet, but it runs on more slightly USB hardware (but less than the CDC subset). However, its main claim to fame is being able to connect directly to recent versions of Windows, using drivers that Microsoft bundles and supports, making it much simpler to network with Windows.

There is also support for user mode gadget drivers, using `gadgetfs`. This provides a User Mode API that presents each endpoint as a single file descriptor. I/O is done using normal `read()` and `read()` calls. Familiar tools like GDB and pthreads can be used to develop and debug user mode drivers, so that once a robust controller driver is available many applications for it won't require new kernel mode software. Linux 2.6 Async I/O (AIO) support is available, so that user mode software can stream data with only slightly more overhead than a kernel driver.

There's a USB Mass Storage class driver, which provides a different solution for interoperability with systems such as MS-Windows and MacOS. That Mass Storage driver uses a file or block device as backing store for a drive, like the `loop` driver. The USB host uses the BBB, CB, or CBI versions of the mass storage class specification, using transparent SCSI commands to access the data from the backing store.

There's a "serial line" driver, useful for TTY style operation over USB. The latest version of that driver supports CDC ACM style operation, like a USB modem, and so on most hardware it can interoperate easily with MS-Windows. One interesting use of that driver is in boot firmware (like a BIOS), which can sometimes use that model with very small systems without real serial lines.

Support for other kinds of gadget is expected to be developed and contributed over time, as this driver framework evolves.

20.2.6 USB On-The-GO (OTG)

USB OTG support on Linux 2.6 was initially developed by Texas Instruments for OMAP 16xx and 17xx series processors. Other OTG systems should work in similar ways, but the hardware level details could be very different.

Systems need specialized hardware support to implement OTG, notably including a special Mini-AB jack and associated transceiver to support Dual-Role operation: they can act either as a host, using the standard Linux-USB host side driver stack, or as a peripheral, using this `gadget` framework. To do that, the system software relies on small additions to those programming interfaces, and on a new internal component (here called an "OTG Controller") affecting which driver stack connects to the OTG port. In each role, the system can re-use the existing pool of hardware-neutral drivers, layered on top of the controller driver interfaces (`usb_bus` or `usb_gadget`). Such drivers need at most minor changes, and most of the calls added to support OTG can also benefit non-OTG products.

- Gadget drivers test the `is_otg` flag, and use it to determine whether or not to include an OTG descriptor in each of their configurations.
- Gadget drivers may need changes to support the two new OTG protocols, exposed in new gadget attributes such as `b_hnp_enable` flag. HNP support should be reported through a user interface (two LEDs could suffice), and is triggered in some cases when the host suspends the peripheral. SRP support can be user-initiated just like remote wakeup, probably by pressing the same button.
- On the host side, USB device drivers need to be taught to trigger HNP at appropriate moments, using `usb_suspend_device()`. That also conserves battery power, which is useful even for non-OTG configurations.
- Also on the host side, a driver must support the OTG "Targeted Peripheral List". That's just a whitelist, used to reject peripherals not supported with a given Linux OTG host. This whitelist is product-specific; each product must modify `otg_whitelist.h` to match its interoperability specification.

  Non-OTG Linux hosts, like PCs and workstations, normally have some solution for adding drivers, so that peripherals that aren't recognized can eventually be supported. That approach is unreasonable for consumer products that may never have their firmware upgraded, and where it's usually unrealistic to expect traditional PC/workstation/server kinds of support model to work. For example, it's often impractical to change device firmware once the product has been distributed, so driver bugs can't normally be fixed if they're found after shipment.

Additional changes are needed below those hardware-neutral `usb_bus` and `usb_gadget` driver interfaces; those aren't discussed here in any detail. Those affect the hardware-specific code for each USB Host or Peripheral controller, and how the HCD initializes (since OTG can be active only on a single port). They also involve what may be called an OTG Controller Driver, managing the OTG transceiver and the OTG state machine logic as well as much of the root hub behavior for the OTG port. The OTG controller driver needs to activate and deactivate USB controllers depending on the relevant device role. Some related changes were needed inside usbcore, so that it can identify OTG-capable devices and respond appropriately to HNP or SRP protocols.

20.3 USB Anchors

20.3.1 What is anchor?

A USB driver needs to support some callbacks requiring a driver to cease all IO to an interface. To do so, a driver has to keep track of the URBs it has submitted to know they' ve all completed or to call usb_kill_urb for them. The anchor is a data structure takes care of keeping track of URBs and provides methods to deal with multiple URBs.

20.3.2 Allocation and Initialisation

There' s no API to allocate an anchor. It is simply declared as struct usb_anchor. `init_usb_anchor()` must be called to initialise the data structure.

20.3.3 Deallocation

Once it has no more URBs associated with it, the anchor can be freed with normal memory management operations.

20.3.4 Association and disassociation of URBs with anchors

An association of URBs to an anchor is made by an explicit call to `usb_anchor_urb()`. The association is maintained until an URB is finished by (successful) completion. Thus disassociation is automatic. A function is provided to forcibly finish (kill) all URBs associated with an anchor. Furthermore, disassociation can be made with `usb_unanchor_urb()`

20.3.5 Operations on multitudes of URBs

`usb_kill_anchored_urbs()`

This function kills all URBs associated with an anchor. The URBs are called in the reverse temporal order they were submitted. This way no data can be reordered.

`usb_unlink_anchored_urbs()`

This function unlinks all URBs associated with an anchor. The URBs are processed in the reverse temporal order they were submitted. This is similar to `usb_kill_anchored_urbs()`, but it will not sleep. Therefore no guarantee is made that the URBs have been unlinked when the call returns. They may be unlinked later but will be unlinked in finite time.

usb_scuttle_anchored_urbs()

All URBs of an anchor are unanchored en masse.

usb_wait_anchor_empty_timeout()

This function waits for all URBs associated with an anchor to finish or a timeout, whichever comes first. Its return value will tell you whether the timeout was reached.

usb_anchor_empty()

Returns true if no URBs are associated with an anchor. Locking is the caller's responsibility.

usb_get_from_anchor()

Returns the oldest anchored URB of an anchor. The URB is unanchored and returned with a reference. As you may mix URBs to several destinations in one anchor you have no guarantee the chronologically first submitted URB is returned.

20.4 USB bulk streams

20.4.1 Background

Bulk endpoint streams were added in the USB 3.0 specification. Streams allow a device driver to overload a bulk endpoint so that multiple transfers can be queued at once.

Streams are defined in sections 4.4.6.4 and 8.12.1.4 of the Universal Serial Bus 3.0 specification at https://www.usb.org/developers/docs/ The USB Attached SCSI Protocol, which uses streams to queue multiple SCSI commands, can be found on the T10 website (https://t10.org/).

20.4.2 Device-side implications

Once a buffer has been queued to a stream ring, the device is notified (through an out-of-band mechanism on another endpoint) that data is ready for that stream ID. The device then tells the host which "stream" it wants to start. The host can also initiate a transfer on a stream without the device asking, but the device can refuse that transfer. Devices can switch between streams at any time.

20.4.3 Driver implications

```
int usb_alloc_streams(struct usb_interface *interface,
              struct usb_host_endpoint **eps, unsigned int num_eps,
              unsigned int num_streams, gfp_t mem_flags);
```

Device drivers will call this API to request that the host controller driver allocate memory so the driver can use up to num_streams stream IDs. They must pass an array of usb_host_endpoints that need to be setup with similar stream IDs. This is to ensure that a UASP driver will be able to use the same stream ID for the bulk IN and OUT endpoints used in a Bi-directional command sequence.

The return value is an error condition (if one of the endpoints doesn't support streams, or the xHCI driver ran out of memory), or the number of streams the host controller allocated for this endpoint. The xHCI host controller hardware declares how many stream IDs it can support, and each bulk endpoint on a SuperSpeed device will say how many stream IDs it can handle. Therefore, drivers should be able to deal with being allocated less stream IDs than they requested.

Do NOT call this function if you have URBs enqueued for any of the endpoints passed in as arguments. Do not call this function to request less than two streams.

Drivers will only be allowed to call this API once for the same endpoint without calling `usb_free_streams()`. This is a simplification for the xHCI host controller driver, and may change in the future.

20.4.4 Picking new Stream IDs to use

Stream ID 0 is reserved, and should not be used to communicate with devices. If `usb_alloc_streams()` returns with a value of N, you may use streams 1 though N. To queue an URB for a specific stream, set the urb->stream_id value. If the endpoint does not support streams, an error will be returned.

Note that new API to choose the next stream ID will have to be added if the xHCI driver supports secondary stream IDs.

20.4.5 Clean up

If a driver wishes to stop using streams to communicate with the device, it should call:

```
void usb_free_streams(struct usb_interface *interface,
              struct usb_host_endpoint **eps, unsigned int num_eps,
              gfp_t mem_flags);
```

All stream IDs will be deallocated when the driver releases the interface, to ensure that drivers that don't support streams will be able to use the endpoint.

20.5 USB core callbacks

20.5.1 What callbacks will usbcore do?

Usbcore will call into a driver through callbacks defined in the driver structure and through the completion handler of URBs a driver submits. Only the former are in the scope of this document. These two kinds of callbacks are completely independent of each other. Information on the completion callback can be found in USB Request Block (URB).

The callbacks defined in the driver structure are:

1. Hotplugging callbacks:

- **@probe:** Called to see if the driver is willing to manage a particular interface on a device.
- **@disconnect:** Called when the interface is no longer accessible, usually because its device has been (or is being) disconnected or the driver module is being unloaded.

2. Odd backdoor through usbfs:

- **@ioctl:** Used for drivers that want to talk to userspace through the "usbfs" filesystem. This lets devices provide ways to expose information to user space regardless of where they do (or don't) show up otherwise in the filesystem.

3. Power management (PM) callbacks:

- **@suspend:** Called when the device is going to be suspended.
- **@resume:** Called when the device is being resumed.
- **@reset_resume:** Called when the suspended device has been reset instead of being resumed.

4. Device level operations:

- **@pre_reset:** Called when the device is about to be reset.
- **@post_reset:** Called after the device has been reset

The ioctl interface (2) should be used only if you have a very good reason. Sysfs is preferred these days. The PM callbacks are covered separately in Power Management for USB.

20.5.2 Calling conventions

All callbacks are mutually exclusive. There's no need for locking against other USB callbacks. All callbacks are called from a task context. You may sleep. However, it is important that all sleeps have a small fixed upper limit in time. In particular you must not call out to user space and await results.

20.5.3 Hotplugging callbacks

These callbacks are intended to associate and disassociate a driver with an interface. A driver's bond to an interface is exclusive.

The probe() callback

```
int (*probe) (struct usb_interface *intf,
              const struct usb_device_id *id);
```

Accept or decline an interface. If you accept the device return 0, otherwise -ENODEV or -ENXIO. Other error codes should be used only if a genuine error occurred during initialisation which prevented a driver from accepting a device that would else have been accepted. You are strongly encouraged to use usbcore's facility, usb_set_intfdata(), to associate a data structure with an interface, so that you know which internal state and identity you associate with a particular interface. The device will not be suspended and you may do IO to the interface you are called for and endpoint 0 of the device. Device initialisation that doesn't take too long is a good idea here.

The disconnect() callback

```
void (*disconnect) (struct usb_interface *intf);
```

This callback is a signal to break any connection with an interface. You are not allowed any IO to a device after returning from this callback. You also may not do any other operation that may interfere with another driver bound the interface, eg. a power management operation. If you are called due to a physical disconnection, all your URBs will be killed by usbcore. Note that in this case disconnect will be called some time after the physical disconnection. Thus your driver must be prepared to deal with failing IO even prior to the callback.

20.5.4 Device level callbacks

pre_reset

```
int (*pre_reset)(struct usb_interface *intf);
```

A driver or user space is triggering a reset on the device which contains the interface passed as an argument. Cease IO, wait for all outstanding URBs to complete, and save any device state you need to restore. No more URBs may be submitted until the post_reset method is called.

If you need to allocate memory here, use GFP_NOIO or GFP_ATOMIC, if you are in atomic context.

post_reset

```
int (*post_reset)(struct usb_interface *intf);
```

The reset has completed. Restore any saved device state and begin using the device again.

If you need to allocate memory here, use GFP_NOIO or GFP_ATOMIC, if you are in atomic context.

20.5.5 Call sequences

No callbacks other than probe will be invoked for an interface that isn't bound to your driver.

Probe will never be called for an interface bound to a driver. Hence following a successful probe, disconnect will be called before there is another probe for the same interface.

Once your driver is bound to an interface, disconnect can be called at any time except in between pre_reset and post_reset. pre_reset is always followed by post_reset, even if the reset failed or the device has been unplugged.

suspend is always followed by one of: resume, reset_resume, or disconnect.

20.6 USB DMA

In Linux 2.5 kernels (and later), USB device drivers have additional control over how DMA may be used to perform I/O operations. The APIs are detailed in the kernel usb programming guide (kerneldoc, from the source code).

20.6.1 API overview

The big picture is that USB drivers can continue to ignore most DMA issues, though they still must provide DMA-ready buffers (see `Documentation/DMA-API-HOWTO.txt`). That's how they've worked through the 2.4 (and earlier) kernels, or they can now be DMA-aware.

DMA-aware usb drivers:

- New calls enable DMA-aware drivers, letting them allocate dma buffers and manage dma mappings for existing dma-ready buffers (see below).
- URBs have an additional "transfer_dma" field, as well as a transfer_flags bit saying if it's valid. (Control requests also have "setup_dma", but drivers must not use it.)
- "usbcore" will map this DMA address, if a DMA-aware driver didn't do it first and set `URB_NO_TRANSFER_DMA_MAP`. HCDs don't manage dma mappings for URBs.

- There's a new "generic DMA API", parts of which are usable by USB device drivers. Never use dma_set_mask() on any USB interface or device; that would potentially break all devices sharing that bus.

20.6.2 Eliminating copies

It's good to avoid making CPUs copy data needlessly. The costs can add up, and effects like cache-trashing can impose subtle penalties.

- If you're doing lots of small data transfers from the same buffer all the time, that can really burn up resources on systems which use an IOMMU to manage the DMA mappings. It can cost MUCH more to set up and tear down the IOMMU mappings with each request than perform the I/O!

  For those specific cases, USB has primitives to allocate less expensive memory. They work like kmalloc and kfree versions that give you the right kind of addresses to store in urb->transfer_buffer and urb->transfer_dma. You'd also set `URB_NO_TRANSFER_DMA_MAP` in urb->transfer_flags:

```
void *usb_alloc_coherent (struct usb_device *dev, size_t size,
        int mem_flags, dma_addr_t *dma);

void usb_free_coherent (struct usb_device *dev, size_t size,
        void *addr, dma_addr_t dma);
```

  Most drivers should **NOT** be using these primitives; they don't need to use this type of memory ("dma-coherent"), and memory returned from `kmalloc()` will work just fine.

  The memory buffer returned is "dma-coherent"; sometimes you might need to force a consistent memory access ordering by using memory barriers. It's not using a streaming DMA mapping, so it's good for small transfers on systems where the I/O would otherwise thrash an IOMMU mapping. (See `Documentation/DMA-API-HOWTO.txt` for definitions of "coherent" and "streaming" DMA mappings.)

  Asking for 1/Nth of a page (as well as asking for N pages) is reasonably space-efficient.

  On most systems the memory returned will be uncached, because the semantics of dma-coherent memory require either bypassing CPU caches or using cache hardware with bus-snooping support. While x86 hardware has such bus-snooping, many other systems use software to flush cache lines to prevent DMA conflicts.

- Devices on some EHCI controllers could handle DMA to/from high memory.

  Unfortunately, the current Linux DMA infrastructure doesn't have a sane way to expose these capabilities ⋯and in any case, HIGHMEM is mostly a design wart specific to x86_32. So your best bet is to ensure you never pass a highmem buffer into a USB driver. That's easy; it's the default behavior. Just don't override it; e.g. with `NETIF_F_HIGHDMA`.

  This may force your callers to do some bounce buffering, copying from high memory to "normal" DMA memory. If you can come up with a good way to

fix this issue (for x86_32 machines with over 1 GByte of memory), feel free to submit patches.

20.6.3 Working with existing buffers

Existing buffers aren't usable for DMA without first being mapped into the DMA address space of the device. However, most buffers passed to your driver can safely be used with such DMA mapping. (See the first section of Documentation/DMA-API-HOWTO.txt, titled "What memory is DMA-able?")

- When you're using scatterlists, you can map everything at once. On some systems, this kicks in an IOMMU and turns the scatterlists into single DMA transactions:

```
int usb_buffer_map_sg (struct usb_device *dev, unsigned pipe,
        struct scatterlist *sg, int nents);

void usb_buffer_dmasync_sg (struct usb_device *dev, unsigned pipe,
        struct scatterlist *sg, int n_hw_ents);

void usb_buffer_unmap_sg (struct usb_device *dev, unsigned pipe,
        struct scatterlist *sg, int n_hw_ents);
```

  It's probably easier to use the new `usb_sg_*()` calls, which do the DMA mapping and apply other tweaks to make scatterlist i/o be fast.

- Some drivers may prefer to work with the model that they're mapping large buffers, synchronizing their safe re-use. (If there's no re-use, then let usbcore do the map/unmap.) Large periodic transfers make good examples here, since it's cheaper to just synchronize the buffer than to unmap it each time an urb completes and then re-map it on during resubmission.

  These calls all work with initialized urbs: `urb->dev`, `urb->pipe`, `urb->transfer_buffer`, and `urb->transfer_buffer_length` must all be valid when these calls are used (`urb->setup_packet` must be valid too if urb is a control request):

```
struct urb *usb_buffer_map (struct urb *urb);

void usb_buffer_dmasync (struct urb *urb);

void usb_buffer_unmap (struct urb *urb);
```

  The calls manage `urb->transfer_dma` for you, and set `URB_NO_TRANSFER_DMA_MAP` so that usbcore won't map or unmap the buffer. They cannot be used for setup_packet buffers in control requests.

Note that several of those interfaces are currently commented out, since they don't have current users. See the source code. Other than the dmasync calls (where the underlying DMA primitives have changed), most of them can easily be commented back in if you want to use them.

20.7 USB Request Block (URB)

Revised 2000-Dec-05

Again 2002-Jul-06

Again 2005-Sep-19

Again 2017-Mar-29

Note: The USB subsystem now has a substantial section at The Linux-USB Host Side API section, generated from the current source code. This particular documentation file isn't complete and may not be updated to the last version; don't rely on it except for a quick overview.

20.7.1 Basic concept or 'What is an URB?'

The basic idea of the new driver is message passing, the message itself is called USB Request Block, or URB for short.

- An URB consists of all relevant information to execute any USB transaction and deliver the data and status back.
- Execution of an URB is inherently an asynchronous operation, i.e. the `usb_submit_urb()` call returns immediately after it has successfully queued the requested action.
- Transfers for one URB can be canceled with `usb_unlink_urb()` at any time.
- Each URB has a completion handler, which is called after the action has been successfully completed or canceled. The URB also contains a context-pointer for passing information to the completion handler.
- Each endpoint for a device logically supports a queue of requests. You can fill that queue, so that the USB hardware can still transfer data to an endpoint while your driver handles completion of another. This maximizes use of USB bandwidth, and supports seamless streaming of data to (or from) devices when using periodic transfer modes.

20.7.2 The URB structure

Some of the fields in struct `urb` are:

```
struct urb
{
// (IN) device and pipe specify the endpoint queue
      struct usb_device *dev;         // pointer to associated USB device
      unsigned int pipe;              // endpoint information

      unsigned int transfer_flags;    // URB_ISO_ASAP, URB_SHORT_NOT_OK,␣
↪etc.
```

(continues on next page)

(continued from previous page)

```
// (IN) all urbs need completion routines
      void *context;                  // context for completion routine
      usb_complete_t complete;        // pointer to completion routine

// (OUT) status after each completion
      int status;                     // returned status

// (IN) buffer used for data transfers
      void *transfer_buffer;          // associated data buffer
      u32 transfer_buffer_length;     // data buffer length
      int number_of_packets;          // size of iso_frame_desc

// (OUT) sometimes only part of CTRL/BULK/INTR transfer_buffer is used
      u32 actual_length;              // actual data buffer length

// (IN) setup stage for CTRL (pass a struct usb_ctrlrequest)
      unsigned char *setup_packet;    // setup packet (control only)

// Only for PERIODIC transfers (ISO, INTERRUPT)
  // (IN/OUT) start_frame is set unless URB_ISO_ASAP isn't set
      int start_frame;                // start frame
      int interval;                   // polling interval

  // ISO only: packets are only "best effort"; each can have errors
      int error_count;                // number of errors
      struct usb_iso_packet_descriptor iso_frame_desc[0];
};
```

Your driver must create the “pipe”value using values from the appropriate endpoint descriptor in an interface that it’s claimed.

20.7.3 How to get an URB?

URBs are allocated by calling `usb_alloc_urb()`:

```
struct urb *usb_alloc_urb(int isoframes, int mem_flags)
```

Return value is a pointer to the allocated URB, 0 if allocation failed. The parameter isoframes specifies the number of isochronous transfer frames you want to schedule. For CTRL/BULK/INT, use 0. The mem_flags parameter holds standard memory allocation flags, letting you control (among other things) whether the underlying code may block or not.

To free an URB, use `usb_free_urb()`:

```
void usb_free_urb(struct urb *urb)
```

You may free an urb that you’ve submitted, but which hasn’t yet been returned to you in a completion callback. It will automatically be deallocated when it is no longer in use.

20.7.4 What has to be filled in?

Depending on the type of transaction, there are some inline functions defined in `linux/usb.h` to simplify the initialization, such as `usb_fill_control_urb()`, `usb_fill_bulk_urb()` and `usb_fill_int_urb()`. In general, they need the usb device pointer, the pipe (usual format from usb.h), the transfer buffer, the desired transfer length, the completion handler, and its context. Take a look at the some existing drivers to see how they' re used.

Flags:

- For ISO there are two startup behaviors: Specified start_frame or ASAP.
- For ASAP set `URB_ISO_ASAP` in transfer_flags.

If short packets should NOT be tolerated, set `URB_SHORT_NOT_OK` in transfer_flags.

20.7.5 How to submit an URB?

Just call `usb_submit_urb()`:

```
int usb_submit_urb(struct urb *urb, int mem_flags)
```

The `mem_flags` parameter, such as `GFP_ATOMIC`, controls memory allocation, such as whether the lower levels may block when memory is tight.

It immediately returns, either with status 0 (request queued) or some error code, usually caused by the following:

- Out of memory (`-ENOMEM`)
- Unplugged device (`-ENODEV`)
- Stalled endpoint (`-EPIPE`)
- Too many queued ISO transfers (`-EAGAIN`)
- Too many requested ISO frames (`-EFBIG`)
- Invalid INT interval (`-EINVAL`)
- More than one packet for INT (`-EINVAL`)

After submission, `urb->status` is `-EINPROGRESS`; however, you should never look at that value except in your completion callback.

For isochronous endpoints, your completion handlers should (re)submit URBs to the same endpoint with the `URB_ISO_ASAP` flag, using multi-buffering, to get seamless ISO streaming.

20.7.6 How to cancel an already running URB?

There are two ways to cancel an URB you’ ve submitted but which hasn’ t been returned to your driver yet. For an asynchronous cancel, call `usb_unlink_urb()`:

```
int usb_unlink_urb(struct urb *urb)
```

It removes the urb from the internal list and frees all allocated HW descriptors. The status is changed to reflect unlinking. Note that the URB will not normally have finished when `usb_unlink_urb()` returns; you must still wait for the completion handler to be called.

To cancel an URB synchronously, call `usb_kill_urb()`:

```
void usb_kill_urb(struct urb *urb)
```

It does everything `usb_unlink_urb()` does, and in addition it waits until after the URB has been returned and the completion handler has finished. It also marks the URB as temporarily unusable, so that if the completion handler or anyone else tries to resubmit it they will get a `-EPERM` error. Thus you can be sure that when `usb_kill_urb()` returns, the URB is totally idle.

There is a lifetime issue to consider. An URB may complete at any time, and the completion handler may free the URB. If this happens while `usb_unlink_urb()` or `usb_kill_urb()` is running, it will cause a memory-access violation. The driver is responsible for avoiding this, which often means some sort of lock will be needed to prevent the URB from being deallocated while it is still in use.

On the other hand, since usb_unlink_urb may end up calling the completion handler, the handler must not take any lock that is held when usb_unlink_urb is invoked. The general solution to this problem is to increment the URB’ s reference count while holding the lock, then drop the lock and call usb_unlink_urb or usb_kill_urb, and then decrement the URB’ s reference count. You increment the reference count by calling :c:func`usb_get_urb`:

```
struct urb *usb_get_urb(struct urb *urb)
```

(ignore the return value; it is the same as the argument) and decrement the reference count by calling `usb_free_urb()`. Of course, none of this is necessary if there’ s no danger of the URB being freed by the completion handler.

20.7.7 What about the completion handler?

The handler is of the following type:

```
typedef void (*usb_complete_t)(struct urb *)
```

I.e., it gets the URB that caused the completion call. In the completion handler, you should have a look at `urb->status` to detect any USB errors. Since the context parameter is included in the URB, you can pass information to the completion handler.

Note that even when an error (or unlink) is reported, data may have been transferred. That’s because USB transfers are packetized; it might take sixteen packets

to transfer your 1KByte buffer, and ten of them might have transferred successfully before the completion was called.

> **Warning:** NEVER SLEEP IN A COMPLETION HANDLER.
>
> These are often called in atomic context.

In the current kernel, completion handlers run with local interrupts disabled, but in the future this will be changed, so don't assume that local IRQs are always disabled inside completion handlers.

20.7.8 How to do isochronous (ISO) transfers?

Besides the fields present on a bulk transfer, for ISO, you also also have to set `urb->interval` to say how often to make transfers; it's often one per frame (which is once every microframe for highspeed devices). The actual interval used will be a power of two that's no bigger than what you specify. You can use the `usb_fill_int_urb()` macro to fill most ISO transfer fields.

For ISO transfers you also have to fill a `usb_iso_packet_descriptor` structure, allocated at the end of the URB by `usb_alloc_urb()`, for each packet you want to schedule.

The `usb_submit_urb()` call modifies `urb->interval` to the implemented interval value that is less than or equal to the requested interval value. If `URB_ISO_ASAP` scheduling is used, `urb->start_frame` is also updated.

For each entry you have to specify the data offset for this frame (base is transfer_buffer), and the length you want to write/expect to read. After completion, actual_length contains the actual transferred length and status contains the resulting status for the ISO transfer for this frame. It is allowed to specify a varying length from frame to frame (e.g. for audio synchronisation/adaptive transfer rates). You can also use the length 0 to omit one or more frames (striping).

For scheduling you can choose your own start frame or `URB_ISO_ASAP`. As explained earlier, if you always keep at least one URB queued and your completion keeps (re)submitting a later URB, you'll get smooth ISO streaming (if usb bandwidth utilization allows).

If you specify your own start frame, make sure it's several frames in advance of the current frame. You might want this model if you're synchronizing ISO data with some other event stream.

20.7.9 How to start interrupt (INT) transfers?

Interrupt transfers, like isochronous transfers, are periodic, and happen in intervals that are powers of two (1, 2, 4 etc) units. Units are frames for full and low speed devices, and microframes for high speed ones. You can use the `usb_fill_int_urb()` macro to fill INT transfer fields.

The `usb_submit_urb()` call modifies `urb->interval` to the implemented interval value that is less than or equal to the requested interval value.

In Linux 2.6, unlike earlier versions, interrupt URBs are not automagically restarted when they complete. They end when the completion handler is called, just like other URBs. If you want an interrupt URB to be restarted, your completion handler must resubmit it. s

20.8 Power Management for USB

Author Alan Stern <stern@rowland.harvard.edu>

Date Last-updated: February 2014

20.8.1 What is Power Management?

Power Management (PM) is the practice of saving energy by suspending parts of a computer system when they aren't being used. While a component is `suspended` it is in a nonfunctional low-power state; it might even be turned off completely. A suspended component can be `resumed` (returned to a functional full-power state) when the kernel needs to use it. (There also are forms of PM in which components are placed in a less functional but still usable state instead of being suspended; an example would be reducing the CPU's clock rate. This document will not discuss those other forms.)

When the parts being suspended include the CPU and most of the rest of the system, we speak of it as a "system suspend". When a particular device is turned off while the system as a whole remains running, we call it a "dynamic suspend" (also known as a "runtime suspend" or "selective suspend"). This document concentrates mostly on how dynamic PM is implemented in the USB subsystem, although system PM is covered to some extent (see `Documentation/power/*.rst` for more information about system PM).

System PM support is present only if the kernel was built with `CONFIG_SUSPEND` or `CONFIG_HIBERNATION` enabled. Dynamic PM support

for USB is present whenever the kernel was built with `CONFIG_PM` enabled.

[Historically, dynamic PM support for USB was present only if the kernel had been built with `CONFIG_USB_SUSPEND` enabled (which depended on `CONFIG_PM_RUNTIME`). Starting with the 3.10 kernel release, dynamic PM support for USB was present whenever the kernel was built with `CONFIG_PM_RUNTIME` enabled. The `CONFIG_USB_SUSPEND` option had been eliminated.]

20.8.2 What is Remote Wakeup?

When a device has been suspended, it generally doesn't resume until the computer tells it to. Likewise, if the entire computer has been suspended, it generally doesn't resume until the user tells it to, say by pressing a power button or opening the cover.

However some devices have the capability of resuming by themselves, or asking the kernel to resume them, or even telling the entire computer to resume. This capability goes by several names such as "Wake On LAN"; we will refer to it generically as "remote wakeup". When a device is enabled for remote wakeup and it is suspended, it may resume itself (or send a request to be resumed) in response to some external event. Examples include a suspended keyboard resuming when a key is pressed, or a suspended USB hub resuming when a device is plugged in.

20.8.3 When is a USB device idle?

A device is idle whenever the kernel thinks it's not busy doing anything important and thus is a candidate for being suspended. The exact definition depends on the device's driver; drivers are allowed to declare that a device isn't idle even when there's no actual communication taking place. (For example, a hub isn't considered idle unless all the devices plugged into that hub are already suspended.) In addition, a device isn't considered idle so long as a program keeps its usbfs file open, whether or not any I/O is going on.

If a USB device has no driver, its usbfs file isn't open, and it isn't being accessed through sysfs, then it definitely is idle.

20.8.4 Forms of dynamic PM

Dynamic suspends occur when the kernel decides to suspend an idle device. This is called `autosuspend` for short. In general, a device won't be autosuspended unless it has been idle for some minimum period of time, the so-called idle-delay time.

Of course, nothing the kernel does on its own initiative should prevent the computer or its devices from working properly. If a device has been autosuspended and a program tries to use it, the kernel will automatically resume the device (autoresume). For the same reason, an autosuspended device will usually have remote wakeup enabled, if the device supports remote wakeup.

It is worth mentioning that many USB drivers don't support autosuspend. In fact, at the time of this writing (Linux 2.6.23) the only drivers which do support it are the hub driver, kaweth, asix, usblp, usblcd, and usb-skeleton (which doesn't count). If a non-supporting driver is bound to a device, the device won't be autosuspended. In effect, the kernel pretends the device is never idle.

We can categorize power management events in two broad classes: external and internal. External events are those triggered by some agent outside the USB stack: system suspend/resume (triggered by userspace), manual dynamic resume (also triggered by userspace), and remote wakeup (triggered by the device). Internal events are those triggered within the USB stack: autosuspend and autoresume.

Note that all dynamic suspend events are internal; external agents are not allowed to issue dynamic suspends.

20.8.5 The user interface for dynamic PM

The user interface for controlling dynamic PM is located in the `power/` subdirectory of each USB device's sysfs directory, that is, in `/sys/bus/usb/devices/.../power/` where "..." is the device's ID. The relevant attribute files are: wakeup, control, and `autosuspend_delay_ms`. (There may also be a file named `level`; this file was deprecated as of the 2.6.35 kernel and replaced by the `control` file. In 2.6.38 the `autosuspend` file will be deprecated and replaced by the `autosuspend_delay_ms` file. The only difference is that the newer file expresses the delay in milliseconds whereas the older file uses seconds. Confusingly, both files are present in 2.6.37 but only `autosuspend` works.)

`power/wakeup`

This file is empty if the device does not support remote wakeup. Otherwise the file contains either the word `enabled` or the word `disabled`, and you can write those words to the file. The setting determines whether or not remote wakeup will be enabled when the device is next suspended. (If the setting is changed while the device is suspended, the change won't take effect until the following suspend.)

`power/control`

This file contains one of two words: `on` or `auto`. You can write those words to the file to change the device's setting.

- `on` means that the device should be resumed and autosuspend is not allowed. (Of course, system suspends are still allowed.)
- `auto` is the normal state in which the kernel is allowed to autosuspend and autoresume the device.

(In kernels up to 2.6.32, you could also specify `suspend`, meaning that the device should remain suspended and autoresume was not allowed. This setting is no longer supported.)

`power/autosuspend_delay_ms`

This file contains an integer value, which is the number of milliseconds the device should remain idle before the kernel will autosuspend it (the idle-delay time). The default is 2000. 0 means to autosuspend as soon as the device becomes idle, and negative values mean never to autosuspend. You can write a number to the file to change the autosuspend idle-delay time.

Writing `-1` to `power/autosuspend_delay_ms` and writing `on` to `power/control` do essentially the same thing – they both prevent the device from being autosuspended. Yes, this is a redundancy in the API.

(In 2.6.21 writing `0` to `power/autosuspend` would prevent the device from being autosuspended; the behavior was changed in 2.6.22. The `power/autosuspend`

attribute did not exist prior to 2.6.21, and the `power/level` attribute did not exist prior to 2.6.22. `power/control` was added in 2.6.34, and `power/autosuspend_delay_ms` was added in 2.6.37 but did not become functional until 2.6.38.)

20.8.6 Changing the default idle-delay time

The default autosuspend idle-delay time (in seconds) is controlled by a module parameter in usbcore. You can specify the value when usbcore is loaded. For example, to set it to 5 seconds instead of 2 you would do:

```
modprobe usbcore autosuspend=5
```

Equivalently, you could add to a configuration file in /etc/modprobe.d a line saying:

```
options usbcore autosuspend=5
```

Some distributions load the usbcore module very early during the boot process, by means of a program or script running from an initramfs image. To alter the parameter value you would have to rebuild that image.

If usbcore is compiled into the kernel rather than built as a loadable module, you can add:

```
usbcore.autosuspend=5
```

to the kernel's boot command line.

Finally, the parameter value can be changed while the system is running. If you do:

```
echo 5 >/sys/module/usbcore/parameters/autosuspend
```

then each new USB device will have its autosuspend idle-delay initialized to 5. (The idle-delay values for already existing devices will not be affected.)

Setting the initial default idle-delay to -1 will prevent any autosuspend of any USB device. This has the benefit of allowing you then to enable autosuspend for selected devices.

20.8.7 Warnings

The USB specification states that all USB devices must support power management. Nevertheless, the sad fact is that many devices do not support it very well. You can suspend them all right, but when you try to resume them they disconnect themselves from the USB bus or they stop working entirely. This seems to be especially prevalent among printers and scanners, but plenty of other types of device have the same deficiency.

For this reason, by default the kernel disables autosuspend (the `power/control` attribute is initialized to `on`) for all devices other than hubs. Hubs, at least, appear to be reasonably well-behaved in this regard.

(In 2.6.21 and 2.6.22 this wasn't the case. Autosuspend was enabled by default for almost all USB devices. A number of people experienced problems as a result.)

This means that non-hub devices won't be autosuspended unless the user or a program explicitly enables it. As of this writing there aren't any widespread programs which will do this; we hope that in the near future device managers such as HAL will take on this added responsibility. In the meantime you can always carry out the necessary operations by hand or add them to a udev script. You can also change the idle-delay time; 2 seconds is not the best choice for every device.

If a driver knows that its device has proper suspend/resume support, it can enable autosuspend all by itself. For example, the video driver for a laptop's webcam might do this (in recent kernels they do), since these devices are rarely used and so should normally be autosuspended.

Sometimes it turns out that even when a device does work okay with autosuspend there are still problems. For example, the usbhid driver, which manages keyboards and mice, has autosuspend support. Tests with a number of keyboards show that typing on a suspended keyboard, while causing the keyboard to do a remote wakeup all right, will nonetheless frequently result in lost keystrokes. Tests with mice show that some of them will issue a remote-wakeup request in response to button presses but not to motion, and some in response to neither.

The kernel will not prevent you from enabling autosuspend on devices that can't handle it. It is even possible in theory to damage a device by suspending it at the wrong time. (Highly unlikely, but possible.) Take care.

20.8.8 The driver interface for Power Management

The requirements for a USB driver to support external power management are pretty modest; the driver need only define:

```
.suspend
.resume
.reset_resume
```

methods in its `usb_driver` structure, and the `reset_resume` method is optional. The methods' jobs are quite simple:

- The `suspend` method is called to warn the driver that the device is going to be suspended. If the driver returns a negative error code, the suspend will be aborted. Normally the driver will return 0, in which case it must cancel all outstanding URBs (`usb_kill_urb()`) and not submit any more.
- The `resume` method is called to tell the driver that the device has been resumed and the driver can return to normal operation. URBs may once more be submitted.
- The `reset_resume` method is called to tell the driver that the device has been resumed and it also has been reset. The driver should redo any necessary device initialization, since the device has probably lost most or all of its state (although the interfaces will be in the same altsettings as before the suspend).

If the device is disconnected or powered down while it is suspended, the `disconnect` method will be called instead of the `resume` or `reset_resume` method.

This is also quite likely to happen when waking up from hibernation, as many systems do not maintain suspend current to the USB host controllers during hibernation. (It's possible to work around the hibernation-forces-disconnect problem by using the USB Persist facility.)

The `reset_resume` method is used by the USB Persist facility (see USB device persistence during system suspend) and it can also be used under certain circumstances when `CONFIG_USB_PERSIST` is not enabled. Currently, if a device is reset during a resume and the driver does not have a `reset_resume` method, the driver won't receive any notification about the resume. Later kernels will call the driver's `disconnect` method; 2.6.23 doesn't do this.

USB drivers are bound to interfaces, so their `suspend` and `resume` methods get called when the interfaces are suspended or resumed. In principle one might want to suspend some interfaces on a device (i.e., force the drivers for those interface to stop all activity) without suspending the other interfaces. The USB core doesn't allow this; all interfaces are suspended when the device itself is suspended and all interfaces are resumed when the device is resumed. It isn't possible to suspend or resume some but not all of a device's interfaces. The closest you can come is to unbind the interfaces' drivers.

20.8.9 The driver interface for autosuspend and autoresume

To support autosuspend and autoresume, a driver should implement all three of the methods listed above. In addition, a driver indicates that it supports autosuspend by setting the `.supports_autosuspend` flag in its usb_driver structure. It is then responsible for informing the USB core whenever one of its interfaces becomes busy or idle. The driver does so by calling these six functions:

```
int  usb_autopm_get_interface(struct usb_interface *intf);
void usb_autopm_put_interface(struct usb_interface *intf);
int  usb_autopm_get_interface_async(struct usb_interface *intf);
void usb_autopm_put_interface_async(struct usb_interface *intf);
void usb_autopm_get_interface_no_resume(struct usb_interface *intf);
void usb_autopm_put_interface_no_suspend(struct usb_interface *intf);
```

The functions work by maintaining a usage counter in the usb_interface's embedded device structure. When the counter is > 0 then the interface is deemed to be busy, and the kernel will not autosuspend the interface's device. When the usage counter is = 0 then the interface is considered to be idle, and the kernel may autosuspend the device.

Drivers must be careful to balance their overall changes to the usage counter. Unbalanced "get"s will remain in effect when a driver is unbound from its interface, preventing the device from going into runtime suspend should the interface be bound to a driver again. On the other hand, drivers are allowed to achieve this balance by calling the `usb_autopm_*` functions even after their `disconnect` routine has returned – say from within a work-queue routine – provided they retain an active reference to the interface (via `usb_get_intf` and `usb_put_intf`).

Drivers using the async routines are responsible for their own synchronization and mutual exclusion.

`usb_autopm_get_interface()` increments the usage counter and does

an autoresume if the device is suspended. If the autoresume fails, the counter is decremented back.

`usb_autopm_put_interface()` decrements the usage counter and attempts an autosuspend if the new value is = 0.

`usb_autopm_get_interface_async()` and `usb_autopm_put_interface_async()` do almost the same things as their non-async counterparts. The big difference is that they use a workqueue to do the resume or suspend part of their jobs. As a result they can be called in an atomic context, such as an URB's completion handler, but when they return the device will generally not yet be in the desired state.

`usb_autopm_get_interface_no_resume()` and `usb_autopm_put_interface_no_suspend()` merely increment or decrement the usage counter; they do not attempt to carry out an autoresume or an autosuspend. Hence they can be called in an atomic context.

The simplest usage pattern is that a driver calls `usb_autopm_get_interface()` in its open routine and `usb_autopm_put_interface()` in its close or release routine. But other patterns are possible.

The autosuspend attempts mentioned above will often fail for one reason or another. For example, the `power/control` attribute might be set to `on`, or another interface in the same device might not be idle. This is perfectly normal. If the reason for failure was that the device hasn't been idle for long enough, a timer is scheduled to carry out the operation automatically when the autosuspend idle-delay has expired.

Autoresume attempts also can fail, although failure would mean that the device is no longer present or operating properly. Unlike autosuspend, there's no idle-delay for an autoresume.

20.8.10 Other parts of the driver interface

Drivers can enable autosuspend for their devices by calling:

```
usb_enable_autosuspend(struct usb_device *udev);
```

in their `probe()` routine, if they know that the device is capable of suspending and resuming correctly. This is exactly equivalent to writing `auto` to the device's `power/control` attribute. Likewise, drivers can disable autosuspend by calling:

```
usb_disable_autosuspend(struct usb_device *udev);
```

This is exactly the same as writing `on` to the `power/control` attribute.

Sometimes a driver needs to make sure that remote wakeup is enabled during autosuspend. For example, there's not much point autosuspending a keyboard if the user can't cause the keyboard to do a remote wakeup by typing on it. If the driver sets `intf->needs_remote_wakeup` to 1, the kernel won't autosuspend the device if remote wakeup isn't available. (If the device is already autosuspended, though, setting this flag won't cause the kernel to autoresume it. Normally a driver

would set this flag in its `probe` method, at which time the device is guaranteed not to be autosuspended.)

If a driver does its I/O asynchronously in interrupt context, it should call `usb_autopm_get_interface_async()` before starting output and `usb_autopm_put_interface_async()` when the output queue drains. When it receives an input event, it should call:

```
usb_mark_last_busy(struct usb_device *udev);
```

in the event handler. This tells the PM core that the device was just busy and therefore the next autosuspend idle-delay expiration should be pushed back. Many of the usb_autopm_* routines also make this call, so drivers need to worry only when interrupt-driven input arrives.

Asynchronous operation is always subject to races. For example, a driver may call the `usb_autopm_get_interface_async()` routine at a time when the core has just finished deciding the device has been idle for long enough but not yet gotten around to calling the driver's `suspend` method. The `suspend` method must be responsible for synchronizing with the I/O request routine and the URB completion handler; it should cause autosuspends to fail with -EBUSY if the driver needs to use the device.

External suspend calls should never be allowed to fail in this way, only autosuspend calls. The driver can tell them apart by applying the `PMSG_IS_AUTO()` macro to the message argument to the `suspend` method; it will return True for internal PM events (autosuspend) and False for external PM events.

20.8.11 Mutual exclusion

For external events – but not necessarily for autosuspend or autoresume – the device semaphore (udev->dev.sem) will be held when a `suspend` or `resume` method is called. This implies that external suspend/resume events are mutually exclusive with calls to `probe`, `disconnect`, `pre_reset`, and `post_reset`; the USB core guarantees that this is true of autosuspend/autoresume events as well.

If a driver wants to block all suspend/resume calls during some critical section, the best way is to lock the device and call `usb_autopm_get_interface()` (and do the reverse at the end of the critical section). Holding the device semaphore will block all external PM calls, and the `usb_autopm_get_interface()` will prevent any internal PM calls, even if it fails. (Exercise: Why?)

20.8.12 Interaction between dynamic PM and system PM

Dynamic power management and system power management can interact in a couple of ways.

Firstly, a device may already be autosuspended when a system suspend occurs. Since system suspends are supposed to be as transparent as possible, the device should remain suspended following the system resume. But this theory may not work out well in practice; over time the kernel's behavior in this regard has changed. As of 2.6.37 the policy is to resume all devices during a system resume and let them handle their own runtime suspends afterward.

Secondly, a dynamic power-management event may occur as a system suspend is underway. The window for this is short, since system suspends don't take long (a few seconds usually), but it can happen. For example, a suspended device may send a remote-wakeup signal while the system is suspending. The remote wakeup may succeed, which would cause the system suspend to abort. If the remote wakeup doesn't succeed, it may still remain active and thus cause the system to resume as soon as the system suspend is complete. Or the remote wakeup may fail and get lost. Which outcome occurs depends on timing and on the hardware and firmware design.

20.8.13 xHCI hardware link PM

xHCI host controller provides hardware link power management to usb2.0 (xHCI 1.0 feature) and usb3.0 devices which support link PM. By enabling hardware LPM, the host can automatically put the device into lower power state(L1 for usb2.0 devices, or U1/U2 for usb3.0 devices), which state device can enter and resume very quickly.

The user interface for controlling hardware LPM is located in the `power/` subdirectory of each USB device's sysfs directory, that is, in `/sys/bus/usb/devices/.../power/` where "…" is the device's ID. The relevant attribute files are `usb2_hardware_lpm` and `usb3_hardware_lpm`.

`power/usb2_hardware_lpm`

When a USB2 device which support LPM is plugged to a xHCI host root hub which support software LPM, the host will run a software LPM test for it; if the device enters L1 state and resume successfully and the host supports USB2 hardware LPM, this file will show up and driver will enable hardware LPM for the device. You can write y/Y/1 or n/N/0 to the file to enable/disable USB2 hardware LPM manually. This is for test purpose mainly.

`power/usb3_hardware_lpm_u1` `power/usb3_hardware_lpm_u2`

When a USB 3.0 lpm-capable device is plugged in to a xHCI host which supports link PM, it will check if U1 and U2 exit latencies have been set in the BOS descriptor; if the check is passed and the host supports USB3 hardware LPM, USB3 hardware LPM will be enabled for the device and these files will be created. The files hold a string value (enable or disable) indicating whether or not USB3 hardware LPM U1 or U2 is enabled for the device.

20.8.14 USB Port Power Control

In addition to suspending endpoint devices and enabling hardware controlled link power management, the USB subsystem also has the capability to disable power to ports under some conditions. Power is controlled through `Set/ClearPortFeature(PORT_POWER)` requests to a hub. In the case of a root or platform-internal hub the host controller driver translates `PORT_POWER` requests into platform firmware (ACPI) method calls to set the port power state. For more background see the Linux Plumbers Conference 2012 slides[1] and video[2]:

Upon receiving a `ClearPortFeature(PORT_POWER)` request a USB port is logically off, and may trigger the actual loss of VBUS to the port[3]. VBUS may be maintained in the case where a hub gangs multiple ports into a shared power well causing power to remain until all ports in the gang are turned off. VBUS may also be maintained by hub ports configured for a charging application. In any event a logically off port will lose connection with its device, not respond to hotplug events, and not respond to remote wakeup events.

Warning: turning off a port may result in the inability to hot add a device. Please see "User Interface for Port Power Control" for details.

As far as the effect on the device itself it is similar to what a device goes through during system suspend, i.e. the power session is lost. Any USB device or driver that misbehaves with system suspend will be similarly affected by a port power cycle event. For this reason the implementation shares the same device recovery path (and honors the same quirks) as the system resume path for the hub.

20.8.15 User Interface for Port Power Control

The port power control mechanism uses the PM runtime system. Poweroff is requested by clearing the `power/pm_qos_no_power_off` flag of the port device (defaults to 1). If the port is disconnected it will immediately receive a `ClearPortFeature(PORT_POWER)` request. Otherwise, it will honor the pm runtime rules and require the attached child device and all descendants to be suspended. This mechanism is dependent on the hub advertising port power switching in its hub descriptor (wHubCharacteristics logical power switching mode field).

Note, some interface devices/drivers do not support autosuspend. Userspace may need to unbind the interface drivers before the `usb_device` will suspend. An unbound interface device is suspended by default. When unbinding, be careful to unbind interface drivers, not the driver of the parent usb device. Also, leave hub interface drivers bound. If the driver for the usb device (not interface) is unbound the kernel is no longer able to resume the device. If a hub interface driver is unbound, control of its child ports is lost and all attached child-devices will disconnect. A good rule of thumb is that if the 'driver/module' link for a device

[1] http://dl.dropbox.com/u/96820575/sarah-sharp-lpt-port-power-off2-mini.pdf

[2] http://linuxplumbers.ubicast.tv/videos/usb-port-power-off-kerneluserspace-api/

[3] USB 3.1 Section 10.12

wakeup note: if a device is configured to send wakeup events the port power control implementation will block poweroff attempts on that port.

points to /sys/module/usbcore then unbinding it will interfere with port power control.

Example of the relevant files for port power control. Note, in this example these files are relative to a usb hub device (prefix):

```
prefix=/sys/devices/pci0000:00/0000:00:14.0/usb3/3-1

                attached child device +
             hub port device +         |
hub interface device +       |         |
                     v       v         v
             $prefix/3-1:1.0/3-1-port1/device

$prefix/3-1:1.0/3-1-port1/power/pm_qos_no_power_off
$prefix/3-1:1.0/3-1-port1/device/power/control
$prefix/3-1:1.0/3-1-port1/device/3-1.1:<intf0>/driver/unbind
$prefix/3-1:1.0/3-1-port1/device/3-1.1:<intf1>/driver/unbind
...
$prefix/3-1:1.0/3-1-port1/device/3-1.1:<intfN>/driver/unbind
```

In addition to these files some ports may have a 'peer' link to a port on another hub. The expectation is that all superspeed ports have a hi-speed peer:

```
$prefix/3-1:1.0/3-1-port1/peer -> ../../../../usb2/2-1/2-1:1.0/2-1-port1
../../../../usb2/2-1/2-1:1.0/2-1-port1/peer -> ../../../../usb3/3-1/3-1:1.
↪0/3-1-port1
```

Distinct from 'companion ports', or 'ehci/xhci shared switchover ports' peer ports are simply the hi-speed and superspeed interface pins that are combined into a single usb3 connector. Peer ports share the same ancestor XHCI device.

While a superspeed port is powered off a device may downgrade its connection and attempt to connect to the hi-speed pins. The implementation takes steps to prevent this:

1. Port suspend is sequenced to guarantee that hi-speed ports are powered-off before their superspeed peer is permitted to power-off. The implication is that the setting pm_qos_no_power_off to zero on a superspeed port may not cause the port to power-off until its highspeed peer has gone to its runtime suspend state. Userspace must take care to order the suspensions if it wants to guarantee that a superspeed port will power-off.

2. Port resume is sequenced to force a superspeed port to power-on prior to its highspeed peer.

3. Port resume always triggers an attached child device to resume. After a power session is lost the device may have been removed, or need reset. Resuming the child device when the parent port regains power resolves those states and clamps the maximum port power cycle frequency at the rate the child device can suspend (autosuspend-delay) and resume (reset-resume latency).

Sysfs files relevant for port power control:

<hubdev-portX>/power/pm_qos_no_power_off: This writable flag controls the state of an idle port. Once all children and descen-

dants have suspended the port may suspend/poweroff provided that pm_qos_no_power_off is ‘0’. If pm_qos_no_power_off is ‘1’ the port will remain active/powered regardless of the stats of descendants. Defaults to 1.

<hubdev-portX>/power/runtime_status: This file reflects whether the port is ‘active’ (power is on) or ‘suspended’ (logically off). There is no indication to userspace whether VBUS is still supplied.

<hubdev-portX>/connect_type: An advisory read-only flag to userspace indicating the location and connection type of the port. It returns one of four values ‘hotplug’, ‘hardwired’, ‘not used’, and ‘unknown’. All values, besides unknown, are set by platform firmware.

`hotplug` indicates an externally connectable/visible port on the platform. Typically userspace would choose to keep such a port powered to handle new device connection events.

`hardwired` refers to a port that is not visible but connectable. Examples are internal ports for USB bluetooth that can be disconnected via an external switch or a port with a hardwired USB camera. It is expected to be safe to allow these ports to suspend provided pm_qos_no_power_off is coordinated with any switch that gates connections. Userspace must arrange for the device to be connected prior to the port powering off, or to activate the port prior to enabling connection via a switch.

`not used` refers to an internal port that is expected to never have a device connected to it. These may be empty internal ports, or ports that are not physically exposed on a platform. Considered safe to be powered-off at all times.

`unknown` means platform firmware does not provide information for this port. Most commonly refers to external hub ports which should be considered ‘hotplug’ for policy decisions.

Note:

- since we are relying on the BIOS to get this ACPI information correct, the USB port descriptions may be missing or wrong.
- Take care in clearing `pm_qos_no_power_off`. Once power is off this port will not respond to new connect events.

Once a child device is attached additional constraints are applied before the port is allowed to poweroff.

<child>/power/control: Must be `auto`, and the port will not power down until `<child>/power/runtime_status` reflects the ‘suspended’ state. Default value is controlled by child device driver.

<child>/power/persist: This defaults to 1 for most devices and indicates if kernel can persist the device’s configuration across a power

session loss (suspend / port-power event). When this value is `0` (quirky devices), port poweroff is disabled.

<child>/driver/unbind: Wakeup capable devices will block port poweroff. At this time the only mechanism to clear the usb-internal wakeup-capability for an interface device is to unbind its driver.

Summary of poweroff pre-requisite settings relative to a port device:

```
echo 0 > power/pm_qos_no_power_off
echo 0 > peer/power/pm_qos_no_power_off # if it exists
echo auto > power/control # this is the default value
echo auto > <child>/power/control
echo 1 > <child>/power/persist # this is the default value
```

20.8.16 Suggested Userspace Port Power Policy

As noted above userspace needs to be careful and deliberate about what ports are enabled for poweroff.

The default configuration is that all ports start with `power/pm_qos_no_power_off` set to `1` causing ports to always remain active.

Given confidence in the platform firmware's description of the ports (ACPI _PLD record for a port populates 'connect_type') userspace can clear pm_qos_no_power_off for all 'not used' ports. The same can be done for 'hard-wired' ports provided poweroff is coordinated with any connection switch for the port.

A more aggressive userspace policy is to enable USB port power off for all ports (set `<hubdev-portX>/power/pm_qos_no_power_off` to `0`) when some external factor indicates the user has stopped interacting with the system. For example, a distro may want to enable power off all USB ports when the screen blanks, and re-power them when the screen becomes active. Smart phones and tablets may want to power off USB ports when the user pushes the power button.

20.9 USB hotplugging

20.9.1 Linux Hotplugging

In hotpluggable busses like USB (and Cardbus PCI), end-users plug devices into the bus with power on. In most cases, users expect the devices to become immediately usable. That means the system must do many things, including:

- Find a driver that can handle the device. That may involve loading a kernel module; newer drivers can use module-init-tools to publish their device (and class) support to user utilities.
- Bind a driver to that device. Bus frameworks do that using a device driver's probe() routine.

- Tell other subsystems to configure the new device. Print queues may need to be enabled, networks brought up, disk partitions mounted, and so on. In some cases these will be driver-specific actions.

This involves a mix of kernel mode and user mode actions. Making devices be immediately usable means that any user mode actions can't wait for an administrator to do them: the kernel must trigger them, either passively (triggering some monitoring daemon to invoke a helper program) or actively (calling such a user mode helper program directly).

Those triggered actions must support a system's administrative policies; such programs are called "policy agents" here. Typically they involve shell scripts that dispatch to more familiar administration tools.

Because some of those actions rely on information about drivers (metadata) that is currently available only when the drivers are dynamically linked, you get the best hotplugging when you configure a highly modular system.

20.9.2 Kernel Hotplug Helper (`/sbin/hotplug`)

There is a kernel parameter: `/proc/sys/kernel/hotplug`, which normally holds the pathname `/sbin/hotplug`. That parameter names a program which the kernel may invoke at various times.

The /sbin/hotplug program can be invoked by any subsystem as part of its reaction to a configuration change, from a thread in that subsystem. Only one parameter is required: the name of a subsystem being notified of some kernel event. That name is used as the first key for further event dispatch; any other argument and environment parameters are specified by the subsystem making that invocation.

Hotplug software and other resources is available at:

http://linux-hotplug.sourceforge.net

Mailing list information is also available at that site.

20.9.3 USB Policy Agent

The USB subsystem currently invokes `/sbin/hotplug` when USB devices are added or removed from system. The invocation is done by the kernel hub workqueue [hub_wq], or else as part of root hub initialization (done by init, modprobe, kapmd, etc). Its single command line parameter is the string "usb", and it passes these environment variables:

ACTION	`add, remove`
PRODUCT	USB vendor, product, and version codes (hex)
TYPE	device class codes (decimal)
INTERFACE	interface 0 class codes (decimal)

If "usbdevfs" is configured, DEVICE and DEVFS are also passed. DEVICE is the pathname of the device, and is useful for devices with multiple and/or alternate interfaces that complicate driver selection. By design, USB hotplugging is independent of `usbdevfs`: you can do most essential parts of USB device setup without

using that filesystem, and without running a user mode daemon to detect changes in system configuration.

Currently available policy agent implementations can load drivers for modules, and can invoke driver-specific setup scripts. The newest ones leverage USB module-init-tools support. Later agents might unload drivers.

20.9.4 USB Modutils Support

Current versions of module-init-tools will create a `modules.usbmap` file which contains the entries from each driver's `MODULE_DEVICE_TABLE`. Such files can be used by various user mode policy agents to make sure all the right driver modules get loaded, either at boot time or later.

See `linux/usb.h` for full information about such table entries; or look at existing drivers. Each table entry describes one or more criteria to be used when matching a driver to a device or class of devices. The specific criteria are identified by bits set in "match_flags", paired with field values. You can construct the criteria directly, or with macros such as these, and use driver_info to store more information:

```
USB_DEVICE (vendorId, productId)
    ... matching devices with specified vendor and product ids
USB_DEVICE_VER (vendorId, productId, lo, hi)
    ... like USB_DEVICE with lo <= productversion <= hi
USB_INTERFACE_INFO (class, subclass, protocol)
    ... matching specified interface class info
USB_DEVICE_INFO (class, subclass, protocol)
    ... matching specified device class info
```

A short example, for a driver that supports several specific USB devices and their quirks, might have a MODULE_DEVICE_TABLE like this:

```
static const struct usb_device_id mydriver_id_table[] = {
    { USB_DEVICE (0x9999, 0xaaaa), driver_info: QUIRK_X },
    { USB_DEVICE (0xbbbb, 0x8888), driver_info: QUIRK_Y|QUIRK_Z },
    ...
    { } /* end with an all-zeroes entry */
};
MODULE_DEVICE_TABLE(usb, mydriver_id_table);
```

Most USB device drivers should pass these tables to the USB subsystem as well as to the module management subsystem. Not all, though: some driver frameworks connect using interfaces layered over USB, and so they won't need such a struct `usb_driver`.

Drivers that connect directly to the USB subsystem should be declared something like this:

```
static struct usb_driver mydriver = {
    .name           = "mydriver",
    .id_table       = mydriver_id_table,
    .probe          = my_probe,
    .disconnect     = my_disconnect,
```

(continues on next page)

(continued from previous page)

```
    /*
    if using the usb chardev framework:
        .minor              = MY_USB_MINOR_START,
        .fops               = my_file_ops,
    if exposing any operations through usbdevfs:
        .ioctl              = my_ioctl,
    */
};
```

When the USB subsystem knows about a driver's device ID table, it's used when choosing drivers to probe(). The thread doing new device processing checks drivers' device ID entries from the `MODULE_DEVICE_TABLE` against interface and device descriptors for the device. It will only call `probe()` if there is a match, and the third argument to `probe()` will be the entry that matched.

If you don't provide an `id_table` for your driver, then your driver may get probed for each new device; the third parameter to `probe()` will be `NULL`.

20.10 USB device persistence during system suspend

Author Alan Stern <stern@rowland.harvard.edu>

Date September 2, 2006 (Updated February 25, 2008)

20.10.1 What is the problem?

According to the USB specification, when a USB bus is suspended the bus must continue to supply suspend current (around 1-5 mA). This is so that devices can maintain their internal state and hubs can detect connect-change events (devices being plugged in or unplugged). The technical term is "power session".

If a USB device's power session is interrupted then the system is required to behave as though the device has been unplugged. It's a conservative approach; in the absence of suspend current the computer has no way to know what has actually happened. Perhaps the same device is still attached or perhaps it was removed and a different device plugged into the port. The system must assume the worst.

By default, Linux behaves according to the spec. If a USB host controller loses power during a system suspend, then when the system wakes up all the devices attached to that controller are treated as though they had disconnected. This is always safe and it is the "officially correct" thing to do.

For many sorts of devices this behavior doesn't matter in the least. If the kernel wants to believe that your USB keyboard was unplugged while the system was asleep and a new keyboard was plugged in when the system woke up, who cares? It'll still work the same when you type on it.

Unfortunately problems _can_ arise, particularly with mass-storage devices. The effect is exactly the same as if the device really had been unplugged while the system was suspended. If you had a mounted filesystem on the device, you're out of luck – everything in that filesystem is now inaccessible. This is especially

annoying if your root filesystem was located on the device, since your system will instantly crash.

Loss of power isn't the only mechanism to worry about. Anything that interrupts a power session will have the same effect. For example, even though suspend current may have been maintained while the system was asleep, on many systems during the initial stages of wakeup the firmware (i.e., the BIOS) resets the motherboard's USB host controllers. Result: all the power sessions are destroyed and again it's as though you had unplugged all the USB devices. Yes, it's entirely the BIOS's fault, but that doesn't do _you_ any good unless you can convince the BIOS supplier to fix the problem (lots of luck!).

On many systems the USB host controllers will get reset after a suspend-to-RAM. On almost all systems, no suspend current is available during hibernation (also known as swsusp or suspend-to-disk). You can check the kernel log after resuming to see if either of these has happened; look for lines saying "root hub lost power or was reset".

In practice, people are forced to unmount any filesystems on a USB device before suspending. If the root filesystem is on a USB device, the system can't be suspended at all. (All right, it _can_ be suspended – but it will crash as soon as it wakes up, which isn't much better.)

20.10.2 What is the solution?

The kernel includes a feature called USB-persist. It tries to work around these issues by allowing the core USB device data structures to persist across a power-session disruption.

It works like this. If the kernel sees that a USB host controller is not in the expected state during resume (i.e., if the controller was reset or otherwise had lost power) then it applies a persistence check to each of the USB devices below that controller for which the "persist" attribute is set. It doesn't try to resume the device; that can't work once the power session is gone. Instead it issues a USB port reset and then re-enumerates the device. (This is exactly the same thing that happens whenever a USB device is reset.) If the re-enumeration shows that the device now attached to that port has the same descriptors as before, including the Vendor and Product IDs, then the kernel continues to use the same device structure. In effect, the kernel treats the device as though it had merely been reset instead of unplugged.

The same thing happens if the host controller is in the expected state but a USB device was unplugged and then replugged, or if a USB device fails to carry out a normal resume.

If no device is now attached to the port, or if the descriptors are different from what the kernel remembers, then the treatment is what you would expect. The kernel destroys the old device structure and behaves as though the old device had been unplugged and a new device plugged in.

The end result is that the USB device remains available and usable. Filesystem mounts and memory mappings are unaffected, and the world is now a good and happy place.

Note that the "USB-persist" feature will be applied only to those devices for which it is enabled. You can enable the feature by doing (as root):

```
echo 1 >/sys/bus/usb/devices/.../power/persist
```

where the "…" should be filled in the with the device's ID. Disable the feature by writing 0 instead of 1. For hubs the feature is automatically and permanently enabled and the power/persist file doesn't even exist, so you only have to worry about setting it for devices where it really matters.

20.10.3 Is this the best solution?

Perhaps not. Arguably, keeping track of mounted filesystems and memory mappings across device disconnects should be handled by a centralized Logical Volume Manager. Such a solution would allow you to plug in a USB flash device, create a persistent volume associated with it, unplug the flash device, plug it back in later, and still have the same persistent volume associated with the device. As such it would be more far-reaching than USB-persist.

On the other hand, writing a persistent volume manager would be a big job and using it would require significant input from the user. This solution is much quicker and easier – and it exists now, a giant point in its favor!

Furthermore, the USB-persist feature applies to _all_ USB devices, not just mass-storage devices. It might turn out to be equally useful for other device types, such as network interfaces.

20.10.4 WARNING: USB-persist can be dangerous!!

When recovering an interrupted power session the kernel does its best to make sure the USB device hasn't been changed; that is, the same device is still plugged into the port as before. But the checks aren't guaranteed to be 100% accurate.

If you replace one USB device with another of the same type (same manufacturer, same IDs, and so on) there's an excellent chance the kernel won't detect the change. The serial number string and other descriptors are compared with the kernel's stored values, but this might not help since manufacturers frequently omit serial numbers entirely in their devices.

Furthermore it's quite possible to leave a USB device exactly the same while changing its media. If you replace the flash memory card in a USB card reader while the system is asleep, the kernel will have no way to know you did it. The kernel will assume that nothing has happened and will continue to use the partition tables, inodes, and memory mappings for the old card.

If the kernel gets fooled in this way, it's almost certain to cause data corruption and to crash your system. You'll have no one to blame but yourself.

For those devices with avoid_reset_quirk attribute being set, persist maybe fail because they may morph after reset.

YOU HAVE BEEN WARNED! USE AT YOUR OWN RISK!

That having been said, most of the time there shouldn't be any trouble at all. The USB-persist feature can be extremely useful. Make the most of it.

20.11 USB Error codes

Revised 2004-Oct-21

This is the documentation of (hopefully) all possible error codes (and their interpretation) that can be returned from usbcore.

Some of them are returned by the Host Controller Drivers (HCDs), which device drivers only see through usbcore. As a rule, all the HCDs should behave the same except for transfer speed dependent behaviors and the way certain faults are reported.

20.11.1 Error codes returned by `usb_submit_urb()`

Non-USB-specific:

0	URB submission went fine
`-ENOMEM`	no memory for allocation of internal structures

USB-specific:

-EBUSY	The URB is already active.
-ENODEV	specified USB-device or bus doesn't exist
-ENOENT	specified interface or endpoint does not exist or is not enabled
-ENXIO	host controller driver does not support queuing of this type of urb. (treat as a host controller bug.)
-EINVAL	a) Invalid transfer type specified (or not supported) b) Invalid or unsupported periodic transfer interval c) ISO: attempted to change transfer interval d) ISO: number_of_packets is < 0 e) various other cases
-EXDEV	ISO: URB_ISO_ASAP wasn't specified and all the frames the URB would be scheduled in have already expired.
-EFBIG	Host controller driver can't schedule that many ISO frames.
-EPIPE	The pipe type specified in the URB doesn't match the endpoint's actual type.
-EMSGSIZE	(a) endpoint maxpacket size is zero; it is not usable in the current interface altsetting. (b) ISO packet is larger than the endpoint maxpacket. (c) requested data transfer length is invalid: negative or too large for the host controller.
-ENOSPC	This request would overcommit the usb bandwidth reserved for periodic transfers (interrupt, isochronous).
-ESHUTDOWN	The device or host controller has been disabled due to some problem that could not be worked around.
-EPERM	Submission failed because urb->reject was set.
-EHOSTUNREACH	URB was rejected because the device is suspended.
-ENOEXEC	A control URB doesn't contain a Setup packet.

20.11.2 Error codes returned by `in urb->status` or in `iso_frame_desc[n].status` (for ISO)

USB device drivers may only test urb status values in completion handlers. This is because otherwise there would be a race between HCDs updating these values on one CPU, and device drivers testing them on another CPU.

A transfer' s actual_length may be positive even when an error has been reported. That's because transfers often involve several packets, so that one or more packets could finish before an error stops further endpoint I/O.

For isochronous URBs, the urb status value is non-zero only if the URB is unlinked, the device is removed, the host controller is disabled, or the total transferred length is less than the requested length and the `URB_SHORT_NOT_OK` flag is set. Completion handlers for isochronous URBs should only see `urb->status` set to zero, `-ENOENT`, `-ECONNRESET`, `-ESHUTDOWN`, or `-EREMOTEIO`. Individual frame descriptor status fields may report more status codes.

0	Transfer completed successfully
-ENOENT	URB was synchronously unlinked by usb_unlink_urb()
-EINPROGRESS	URB still pending, no results yet (That is, if drivers see this it's a bug.)
-EPROTO[1],[2]	a) bitstuff error b) no response packet received within the prescribed bus turn-around time c) unknown USB error
-EILSEQ[1],[2]	a) CRC mismatch b) no response packet received within the prescribed bus turn-around time c) unknown USB error Note that often the controller hardware does not distinguish among cases a), b), and c), so a driver cannot tell whether there was a protocol error, a failure to respond (often caused by device disconnect), or some other fault.
-ETIME[2]	No response packet received within the prescribed bus turn-around time. This error may instead be reported as -EPROTO or -EILSEQ.
-ETIMEDOUT	Synchronous USB message functions use this code to indicate timeout expired before the transfer completed, and no other error was reported by HC.
-EPIPE[2]	Endpoint stalled. For non-control endpoints, reset this status with usb_clear_halt().
-ECOMM	During an IN transfer, the host controller received data from an endpoint faster than it could be written to system memory
-ENOSR	During an OUT transfer, the host controller could not retrieve data from system memory fast enough to keep up with the USB data rate
-EOVERFLOW[1]	The amount of data returned by the endpoint was greater than either the max packet size of the endpoint or the remaining buffer size. "Babble".
-EREMOTEIO	The data read from the endpoint did not fill the specified buffer, and URB_SHORT_NOT_OK was set in urb->transfer_flags.
-ENODEV	Device was removed. Often preceded by a burst of other errors, since the hub driver doesn't detect device removal events immediately.
-EXDEV	ISO transfer only partially completed

20.11.3 Error codes returned by usbcore-functions

Note: expect also other submit and transfer status codes

`usb_register()`:

`-EINVAL`	error during registering new driver

`usb_get_*/usb_set_*()`, `usb_control_msg()`, `usb_bulk_msg()`:

`-ETIMEDOUT`	Timeout expired before the transfer completed.

20.12 Writing USB Device Drivers

Author Greg Kroah-Hartman

20.12.1 Introduction

The Linux USB subsystem has grown from supporting only two different types of devices in the 2.2.7 kernel (mice and keyboards), to over 20 different types of devices in the 2.4 kernel. Linux currently supports almost all USB class devices (standard types of devices like keyboards, mice, modems, printers and speakers) and an ever-growing number of vendor-specific devices (such as USB to serial converters, digital cameras, Ethernet devices and MP3 players). For a full list of the different USB devices currently supported, see Resources.

The remaining kinds of USB devices that do not have support on Linux are almost all vendor-specific devices. Each vendor decides to implement a custom protocol to talk to their device, so a custom driver usually needs to be created. Some vendors are open with their USB protocols and help with the creation of Linux drivers, while others do not publish them, and developers are forced to reverse-engineer. See Resources for some links to handy reverse-engineering tools.

Because each different protocol causes a new driver to be created, I have written a generic USB driver skeleton, modelled after the pci-skeleton.c file in the kernel source tree upon which many PCI network drivers have been based. This USB skeleton can be found at drivers/usb/usb-skeleton.c in the kernel source tree. In this article I will walk through the basics of the skeleton driver, explaining the different pieces and what needs to be done to customize it to your specific device.

[1] Error codes like `-EPROTO`, `-EILSEQ` and `-EOVERFLOW` normally indicate hardware problems such as bad devices (including firmware) or cables.

[2] This is also one of several codes that different kinds of host controller use to indicate a transfer has failed because of device disconnect. In the interval before the hub driver starts disconnect processing, devices may receive such fault reports for every request.

20.12.2 Linux USB Basics

If you are going to write a Linux USB driver, please become familiar with the USB protocol specification. It can be found, along with many other useful documents, at the USB home page (see Resources). An excellent introduction to the Linux USB subsystem can be found at the USB Working Devices List (see Resources). It explains how the Linux USB subsystem is structured and introduces the reader to the concept of USB urbs (USB Request Blocks), which are essential to USB drivers.

The first thing a Linux USB driver needs to do is register itself with the Linux USB subsystem, giving it some information about which devices the driver supports and which functions to call when a device supported by the driver is inserted or removed from the system. All of this information is passed to the USB subsystem in the `usb_driver` structure. The skeleton driver declares a `usb_driver` as:

```
static struct usb_driver skel_driver = {
        .name        = "skeleton",
        .probe       = skel_probe,
        .disconnect  = skel_disconnect,
        .fops        = &skel_fops,
        .minor       = USB_SKEL_MINOR_BASE,
        .id_table    = skel_table,
};
```

The variable name is a string that describes the driver. It is used in informational messages printed to the system log. The probe and disconnect function pointers are called when a device that matches the information provided in the `id_table` variable is either seen or removed.

The fops and minor variables are optional. Most USB drivers hook into another kernel subsystem, such as the SCSI, network or TTY subsystem. These types of drivers register themselves with the other kernel subsystem, and any user-space interactions are provided through that interface. But for drivers that do not have a matching kernel subsystem, such as MP3 players or scanners, a method of interacting with user space is needed. The USB subsystem provides a way to register a minor device number and a set of `file_operations` function pointers that enable this user-space interaction. The skeleton driver needs this kind of interface, so it provides a minor starting number and a pointer to its `file_operations` functions.

The USB driver is then registered with a call to `usb_register()`, usually in the driver's init function, as shown here:

```
static int __init usb_skel_init(void)
{
        int result;

        /* register this driver with the USB subsystem */
        result = usb_register(&skel_driver);
        if (result < 0) {
                err("usb_register failed for the "__FILE__ "driver."
                    "Error number %d", result);
                return -1;
        }

        return 0;
```

(continues on next page)

(continued from previous page)

```
}
module_init(usb_skel_init);
```

When the driver is unloaded from the system, it needs to deregister itself with the USB subsystem. This is done with the `usb_deregister()` function:

```
static void __exit usb_skel_exit(void)
{
        /* deregister this driver with the USB subsystem */
        usb_deregister(&skel_driver);
}
module_exit(usb_skel_exit);
```

To enable the linux-hotplug system to load the driver automatically when the device is plugged in, you need to create a `MODULE_DEVICE_TABLE`. The following code tells the hotplug scripts that this module supports a single device with a specific vendor and product ID:

```
/* table of devices that work with this driver */
static struct usb_device_id skel_table [] = {
        { USB_DEVICE(USB_SKEL_VENDOR_ID, USB_SKEL_PRODUCT_ID) },
        { }                     /* Terminating entry */
};
MODULE_DEVICE_TABLE (usb, skel_table);
```

There are other macros that can be used in describing a struct `usb_device_id` for drivers that support a whole class of USB drivers. See usb.h for more information on this.

20.12.3 Device operation

When a device is plugged into the USB bus that matches the device ID pattern that your driver registered with the USB core, the probe function is called. The `usb_device` structure, interface number and the interface ID are passed to the function:

```
static int skel_probe(struct usb_interface *interface,
    const struct usb_device_id *id)
```

The driver now needs to verify that this device is actually one that it can accept. If so, it returns 0. If not, or if any error occurs during initialization, an errorcode (such as `-ENOMEM` or `-ENODEV`) is returned from the probe function.

In the skeleton driver, we determine what end points are marked as bulk-in and bulk-out. We create buffers to hold the data that will be sent and received from the device, and a USB urb to write data to the device is initialized.

Conversely, when the device is removed from the USB bus, the disconnect function is called with the device pointer. The driver needs to clean any private data that has been allocated at this time and to shut down any pending urbs that are in the USB system.

Now that the device is plugged into the system and the driver is bound to the device, any of the functions in the `file_operations` structure that were passed to

the USB subsystem will be called from a user program trying to talk to the device. The first function called will be open, as the program tries to open the device for I/O. We increment our private usage count and save a pointer to our internal structure in the file structure. This is done so that future calls to file operations will enable the driver to determine which device the user is addressing. All of this is done with the following code:

```
/* increment our usage count for the module */
++skel->open_count;

/* save our object in the file's private structure */
file->private_data = dev;
```

After the open function is called, the read and write functions are called to receive and send data to the device. In the `skel_write` function, we receive a pointer to some data that the user wants to send to the device and the size of the data. The function determines how much data it can send to the device based on the size of the write urb it has created (this size depends on the size of the bulk out end point that the device has). Then it copies the data from user space to kernel space, points the urb to the data and submits the urb to the USB subsystem. This can be seen in the following code:

```
/* we can only write as much as 1 urb will hold */
bytes_written = (count > skel->bulk_out_size) ? skel->bulk_out_size :␣
↪count;

/* copy the data from user space into our urb */
copy_from_user(skel->write_urb->transfer_buffer, buffer, bytes_written);

/* set up our urb */
usb_fill_bulk_urb(skel->write_urb,
                  skel->dev,
                  usb_sndbulkpipe(skel->dev, skel->bulk_out_endpointAddr),
                  skel->write_urb->transfer_buffer,
                  bytes_written,
                  skel_write_bulk_callback,
                  skel);

/* send the data out the bulk port */
result = usb_submit_urb(skel->write_urb);
if (result) {
        err("Failed submitting write urb, error %d", result);
}
```

When the write urb is filled up with the proper information using the `usb_fill_bulk_urb()` function, we point the urb's completion callback to call our own `skel_write_bulk_callback` function. This function is called when the urb is finished by the USB subsystem. The callback function is called in interrupt context, so caution must be taken not to do very much processing at that time. Our implementation of `skel_write_bulk_callback` merely reports if the urb was completed successfully or not and then returns.

The read function works a bit differently from the write function in that we do not use an urb to transfer data from the device to the driver. Instead we call the `usb_bulk_msg()` function, which can be used to send or receive data from a

device without having to create urbs and handle urb completion callback functions. We call the usb_bulk_msg() function, giving it a buffer into which to place any data received from the device and a timeout value. If the timeout period expires without receiving any data from the device, the function will fail and return an error message. This can be shown with the following code:

```
/* do an immediate bulk read to get data from the device */
retval = usb_bulk_msg (skel->dev,
                       usb_rcvbulkpipe (skel->dev,
                       skel->bulk_in_endpointAddr),
                       skel->bulk_in_buffer,
                       skel->bulk_in_size,
                       &count, HZ*10);
/* if the read was successful, copy the data to user space */
if (!retval) {
        if (copy_to_user (buffer, skel->bulk_in_buffer, count))
                retval = -EFAULT;
        else
                retval = count;
}
```

The usb_bulk_msg() function can be very useful for doing single reads or writes to a device; however, if you need to read or write constantly to a device, it is recommended to set up your own urbs and submit them to the USB subsystem.

When the user program releases the file handle that it has been using to talk to the device, the release function in the driver is called. In this function we decrement our private usage count and wait for possible pending writes:

```
/* decrement our usage count for the device */
--skel->open_count;
```

One of the more difficult problems that USB drivers must be able to handle smoothly is the fact that the USB device may be removed from the system at any point in time, even if a program is currently talking to it. It needs to be able to shut down any current reads and writes and notify the user-space programs that the device is no longer there. The following code (function skel_delete) is an example of how to do this:

```
static inline void skel_delete (struct usb_skel *dev)
{
    kfree (dev->bulk_in_buffer);
    if (dev->bulk_out_buffer != NULL)
        usb_free_coherent (dev->udev, dev->bulk_out_size,
            dev->bulk_out_buffer,
            dev->write_urb->transfer_dma);
    usb_free_urb (dev->write_urb);
    kfree (dev);
}
```

If a program currently has an open handle to the device, we reset the flag device_present. For every read, write, release and other functions that expect a device to be present, the driver first checks this flag to see if the device is still present. If not, it releases that the device has disappeared, and a -ENODEV error is returned to the user-space program. When the release function is eventually called, it determines if there is no device and if not, it does the cleanup that the

`skel_disconnect` function normally does if there are no open files on the device (see Listing 5).

20.12.4 Isochronous Data

This usb-skeleton driver does not have any examples of interrupt or isochronous data being sent to or from the device. Interrupt data is sent almost exactly as bulk data is, with a few minor exceptions. Isochronous data works differently with continuous streams of data being sent to or from the device. The audio and video camera drivers are very good examples of drivers that handle isochronous data and will be useful if you also need to do this.

20.12.5 Conclusion

Writing Linux USB device drivers is not a difficult task as the usb-skeleton driver shows. This driver, combined with the other current USB drivers, should provide enough examples to help a beginning author create a working driver in a minimal amount of time. The linux-usb-devel mailing list archives also contain a lot of helpful information.

20.13 Synopsys DesignWare Core SuperSpeed USB 3.0 Controller

Author Felipe Balbi <felipe.balbi@linux.intel.com>

Date April 2017

20.13.1 Introduction

The Synopsys DesignWare Core SuperSpeed USB 3.0 Controller (hereinafter referred to as DWC3) is a USB SuperSpeed compliant controller which can be configured in one of 4 ways:

1. Peripheral-only configuration
2. Host-only configuration
3. Dual-Role configuration

4. Hub configuration

Linux currently supports several versions of this controller. In all likelyhood, the version in your SoC is already supported. At the time of this writing, known tested versions range from 2.02a to 3.10a. As a rule of thumb, anything above 2.02a should work reliably well.

Currently, we have many known users for this driver. In alphabetical order:

1. Cavium
2. Intel Corporation
3. Qualcomm
4. Rockchip
5. ST
6. Samsung
7. Texas Instruments
8. Xilinx

20.13.2 Summary of Features

For details about features supported by your version of DWC3, consult your IP team and/or Synopsys DesignWare Core SuperSpeed USB 3.0 Controller Databook. Following is a list of features supported by the driver at the time of this writing:

1. Up to 16 bidirectional endpoints (including the control pipe - ep0)
2. Flexible endpoint configuration
3. Simultaneous IN and OUT transfer support
4. Scatter-list support
5. Up to 256 TRBs[1] per endpoint
6. Support for all transfer types (Control, Bulk, Interrupt, and Isochronous)
7. SuperSpeed Bulk Streams
8. Link Power Management
9. Trace Events for debugging
10. DebugFS[3] interface

These features have all been exercised with many of the **in-tree** gadget drivers. We have verified both ConfigFS[4] and legacy gadget drivers.

[1] Transfer Request Block
[3] The Debug File System
[4] The Config File System

20.13.3 Driver Design

The DWC3 driver sits on the drivers/usb/dwc3/ directory. All files related to this driver are in this one directory. This makes it easy for new-comers to read the code and understand how it behaves.

Because of DWC3's configuration flexibility, the driver is a little complex in some places but it should be rather straightforward to understand.

The biggest part of the driver refers to the Gadget API.

20.13.4 Known Limitations

Like any other HW, DWC3 has its own set of limitations. To avoid constant questions about such problems, we decided to document them here and have a single location to where we could point users.

OUT Transfer Size Requirements

According to Synopsys Databook, all OUT transfer TRBs[1] must have their size field set to a value which is integer divisible by the endpoint's wMaxPacketSize. This means that e.g. in order to receive a Mass Storage CBW[5], req->length must either be set to a value that's divisible by wMaxPacketSize (1024 on SuperSpeed, 512 on HighSpeed, etc), or DWC3 driver must add a Chained TRB pointing to a throw-away buffer for the remaining length. Without this, OUT transfers will **NOT** start.

Note that as of this writing, this won't be a problem because DWC3 is fully capable of appending a chained TRB for the remaining length and completely hide this detail from the gadget driver. It's still worth mentioning because this seems to be the largest source of queries about DWC3 and non-working transfers.

TRB Ring Size Limitation

We, currently, have a hard limit of 256 TRBs[1] per endpoint, with the last TRB being a Link TRB[2] pointing back to the first. This limit is arbitrary but it has the benefit of adding up to exactly 4096 bytes, or 1 Page.

DWC3 driver will try its best to cope with more than 255 requests and, for the most part, it should work normally. However this is not something that has been exercised very frequently. If you experience any problems, see section **Reporting Bugs** below.

[5] Command Block Wrapper

[2] Transfer Request Block pointing to another Transfer Request Block.

20.13.5 Reporting Bugs

Whenever you encounter a problem with DWC3, first and foremost you should make sure that:

1. You're running latest tag from Linus' tree
2. You can reproduce the error without any out-of-tree changes to DWC3
3. You have checked that it's not a fault on the host machine

After all these are verified, then here's how to capture enough information so we can be of any help to you.

Required Information

DWC3 relies exclusively on Trace Events for debugging. Everything is exposed there, with some extra bits being exposed to DebugFS[3].

In order to capture DWC3's Trace Events you should run the following commands **before** plugging the USB cable to a host machine:

```
# mkdir -p /d
# mkdir -p /t
# mount -t debugfs none /d
# mount -t tracefs none /t
# echo 81920 > /t/buffer_size_kb
# echo 1 > /t/events/dwc3/enable
```

After this is done, you can connect your USB cable and reproduce the problem. As soon as the fault is reproduced, make a copy of files `trace` and `regdump`, like so:

```
# cp /t/trace /root/trace.txt
# cat /d/*dwc3*/regdump > /root/regdump.txt
```

Make sure to compress `trace.txt` and `regdump.txt` in a tarball and email it to me with linux-usb in Cc. If you want to be extra sure that I'll help you, write your subject line in the following format:

> **[BUG REPORT] usb: dwc3: Bug while doing XYZ**

On the email body, make sure to detail what you doing, which gadget driver you were using, how to reproduce the problem, what SoC you're using, which OS (and its version) was running on the Host machine.

With all this information, we should be able to understand what's going on and be helpful to you.

20.13.6 Debugging

First and foremost a disclaimer:

```
DISCLAIMER: The information available on DebugFS and/or TraceFS can
change at any time at any Major Linux Kernel Release. If writing
scripts, do **NOT** assume information to be available in the
current format.
```

With that out of the way, let's carry on.

If you're willing to debug your own problem, you deserve a round of applause :-)

Anyway, there isn't much to say here other than Trace Events will be really helpful in figuring out issues with DWC3. Also, access to Synopsys Databook will be **really** valuable in this case.

A USB Sniffer can be helpful at times but it's not entirely required, there's a lot that can be understood without looking at the wire.

Feel free to email me and Cc linux-usb if you need any help.

DebugFS

`DebugFS` is very good for gathering snapshots of what's going on with DWC3 and/or any endpoint.

On DWC3's `DebugFS` directory, you will find the following files and directories:

`ep[0..15]{in,out}/` `link_state` `regdump` `testmode`

link_state

When read, `link_state` will print out one of `U0`, `U1`, `U2`, `U3`, `SS.Disabled`, `RX.Detect`, `SS.Inactive`, `Polling`, `Recovery`, `Hot Reset`, `Compliance`, `Loopback`, `Reset`, `Resume` or `UNKNOWN link state`.

This file can also be written to in order to force link to one of the states above.

regdump

File name is self-explanatory. When read, `regdump` will print out a register dump of DWC3. Note that this file can be grepped to find the information you want.

testmode

When read, `testmode` will print out a name of one of the specified USB 2.0 Test-modes (`test_j`, `test_k`, `test_se0_nak`, `test_packet`, `test_force_enable`) or the string `no test` in case no tests are currently being executed.

In order to start any of these test modes, the same strings can be written to the file and DWC3 will enter the requested test mode.

ep[0..15]{in,out}

For each endpoint we expose one directory following the naming convention `ep$num$dir` (ep0in, ep0out, ep1in, ⋯). Inside each of these directories you will find the following files:

`descriptor_fetch_queue` `event_queue` `rx_fifo_queue` `rx_info_queue` `rx_request_queue` `transfer_type` `trb_ring` `tx_fifo_queue` `tx_request_queue`

With access to Synopsys Databook, you can decode the information on them.

transfer_type

When read, `transfer_type` will print out one of `control`, `bulk`, `interrupt` or `isochronous` depending on what the endpoint descriptor says. If the endpoint hasn't been enabled yet, it will print `--`.

trb_ring

When read, `trb_ring` will print out details about all TRBs on the ring. It will also tell you where our enqueue and dequeue pointers are located in the ring:

```

Trace Events

DWC3 also provides several trace events which help us gathering information about the behavior of the driver during runtime.

In order to use these events, you must enable `CONFIG_FTRACE` in your kernel config.

For details about how enable DWC3 events, see section **Reporting Bugs**.

The following subsections will give details about each Event Class and each Event defined by DWC3.

MMIO

It is sometimes useful to look at every MMIO access when looking for bugs. Because of that, DWC3 offers two Trace Events (one for dwc3_readl() and one for dwc3_writel()). `TP_printk` follows:

```
TP_printk("addr %p value %08x", __entry->base + __entry->offset,
              __entry->value)
```

Interrupt Events

Every IRQ event can be logged and decoded into a human readable string. Because every event will be different, we don’t give an example other than the `TP_printk` format used:

```
TP_printk("event (%08x): %s", __entry->event,
              dwc3_decode_event(__entry->event, __entry->ep0state))
```

Control Request

Every USB Control Request can be logged to the trace buffer. The output format is:

```
TP_printk("%s", dwc3_decode_ctrl(__entry->bRequestType,
                                 __entry->bRequest, __entry->wValue,
                                 __entry->wIndex, __entry->wLength)
)
```

Note that Standard Control Requests will be decoded into human-readable strings with their respective arguments. Class and Vendor requests will be printed out a sequence of 8 bytes in hex format.

Lifetime of a `struct usb_request`

The entire lifetime of a `struct usb_request` can be tracked on the trace buffer. We have one event for each of allocation, free, queueing, dequeueing, and giveback. Output format is:

```
TP_printk("%s: req %p length %u/%u %s%s%s ==> %d",
      __get_str(name), __entry->req, __entry->actual, __entry->length,
      __entry->zero ? "Z" : "z",
      __entry->short_not_ok ? "S" : "s",
      __entry->no_interrupt ? "i" : "I",
      __entry->status
)
```

Generic Commands

We can log and decode every Generic Command with its completion code. Format is:

```
TP_printk("cmd '%s' [%x] param %08x --> status: %s",
      dwc3_gadget_generic_cmd_string(__entry->cmd),
      __entry->cmd, __entry->param,
      dwc3_gadget_generic_cmd_status_string(__entry->status)
)
```

Endpoint Commands

Endpoints commands can also be logged together with completion code. Format is:

```
TP_printk("%s: cmd '%s' [%d] params %08x %08x %08x --> status: %s",
      __get_str(name), dwc3_gadget_ep_cmd_string(__entry->cmd),
      __entry->cmd, __entry->param0,
      __entry->param1, __entry->param2,
      dwc3_ep_cmd_status_string(__entry->cmd_status)
)
```

Lifetime of a TRB

A TRB Lifetime is simple. We are either preparing a TRB or completing it. With these two events, we can see how a TRB changes over time. Format is:

```
TP_printk("%s: %d/%d trb %p buf %08x%08x size %s%d ctrl %08x (%c%c%c%c:%c
↪%c:%s)",
      __get_str(name), __entry->queued, __entry->allocated,
      __entry->trb, __entry->bph, __entry->bpl,
      ({char *s;
      int pcm = ((__entry->size >> 24) & 3) + 1;
      switch (__entry->type) {
      case USB_ENDPOINT_XFER_INT:
      case USB_ENDPOINT_XFER_ISOC:
              switch (pcm) {
              case 1:
                      s = "1x ";
                      break;
              case 2:
                      s = "2x ";
                      break;
              case 3:
                      s = "3x ";
                      break;
              }
      default:
              s = "";
      } s; }),
      DWC3_TRB_SIZE_LENGTH(__entry->size), __entry->ctrl,
      __entry->ctrl & DWC3_TRB_CTRL_HWO ? 'H' : 'h',
      __entry->ctrl & DWC3_TRB_CTRL_LST ? 'L' : 'l',
      __entry->ctrl & DWC3_TRB_CTRL_CHN ? 'C' : 'c',
      __entry->ctrl & DWC3_TRB_CTRL_CSP ? 'S' : 's',
      __entry->ctrl & DWC3_TRB_CTRL_ISP_IMI ? 'S' : 's',
      __entry->ctrl & DWC3_TRB_CTRL_IOC ? 'C' : 'c',
    dwc3_trb_type_string(DWC3_TRBCTL_TYPE(__entry->ctrl))
)
```

Lifetime of an Endpoint

And endpoint’s lifetime is summarized with enable and disable operations, both of which can be traced. Format is:

```
TP_printk("%s: mps %d/%d streams %d burst %d ring %d/%d flags %c:%c%c%c%c
↪%c:%c:%c",
      __get_str(name), __entry->maxpacket,
      __entry->maxpacket_limit, __entry->max_streams,
      __entry->maxburst, __entry->trb_enqueue,
      __entry->trb_dequeue,
      __entry->flags & DWC3_EP_ENABLED ? 'E' : 'e',
      __entry->flags & DWC3_EP_STALL ? 'S' : 's',
      __entry->flags & DWC3_EP_WEDGE ? 'W' : 'w',
      __entry->flags & DWC3_EP_TRANSFER_STARTED ? 'B' : 'b',
      __entry->flags & DWC3_EP_PENDING_REQUEST ? 'P' : 'p',
```

(continues on next page)

(continued from previous page)

```
      __entry->flags & DWC3_EP_END_TRANSFER_PENDING ? 'E' : 'e',
      __entry->direction ? '<' : '>'
)
```

20.13.7 Structures, Methods and Definitions

struct **dwc3_event_buffer**
Software event buffer representation

Definition

```
struct dwc3_event_buffer {
  void *buf;
  void *cache;
  unsigned length;
  unsigned int            lpos;
  unsigned int            count;
  unsigned int            flags;
#define DWC3_EVENT_PENDING      BIT(0);
  dma_addr_t dma;
  struct dwc3             *dwc;
};
```

Members

buf _THE_ buffer

cache The buffer cache used in the threaded interrupt

length size of this buffer

lpos event offset

count cache of last read event count register

flags flags related to this event buffer

dma dma_addr_t

dwc pointer to DWC controller

struct **dwc3_ep**
device side endpoint representation

Definition

```
struct dwc3_ep {

endpoint usb endpoint

cancelled_list list of cancelled requests for this endpoint

pending_list list of pending requests for this endpoint

started_list list of started requests on this endpoint

regs pointer to first endpoint register

trb_pool array of transaction buffers

trb_pool_dma dma address of **trb_pool**

dwc pointer to DWC controller

saved_state ep state saved during hibernation

flags endpoint flags (wedged, stalled, ⋯)

trb_enqueue enqueue ‘pointer’ into TRB array

trb_dequeue dequeue ‘pointer’ into TRB array

number endpoint number (1 - 15)

type set to bmAttributes & USB_ENDPOINT_XFERTYPE_MASK

resource_index Resource transfer index

frame_number set to the frame number we want this transfer to start (ISOC)

interval the interval on which the ISOC transfer is started

name a human readable name e.g. ep1out-bulk

direction true for TX, false for RX

stream_capable true when streams are enabled

combo_num the test combination BIT[15:14] of the frame number to test isochronous START TRANSFER command failure workaround

start_cmd_status the status of testing START TRANSFER command with combo_num = ‘b00

Members

drd_work workqueue used for role swapping

ep0_trb trb which is used for the ctrl_req

bounce address of bounce buffer

scratchbuf address of scratch buffer

setup_buf used while precessing STD USB requests

ep0_trb_addr dma address of **ep0_trb**

bounce_addr dma address of **bounce**

scratch_addr dma address of scratchbuf

ep0_usb_req dummy req used while handling STD USB requests

ep0_in_setup one control transfer is completed and enter setup phase

lock for synchronizing

dev pointer to our struct device

sysdev pointer to the DMA-capable device

xhci pointer to our xHCI child

xhci_resources struct resources for our **xhci** child

ev_buf struct dwc3_event_buffer pointer

eps endpoint array

gadget device side representation of the peripheral controller

gadget_driver pointer to the gadget driver

clks array of clocks

num_clks number of clocks

reset reset control

usb2_phy pointer to USB2 PHY

usb3_phy pointer to USB3 PHY

usb2_generic_phy pointer to USB2 PHY

usb3_generic_phy pointer to USB3 PHY

phys_ready flag to indicate that PHYs are ready

ulpi pointer to ulpi interface

ulpi_ready flag to indicate that ULPI is initialized

regs base address for our registers

regs_size address space size

dr_mode requested mode of operation

current_dr_role current role of operation when in dual-role mode

desired_dr_role desired role of operation when in dual-role mode

edev extcon handle

edev_nb extcon notifier

hsphy_mode UTMI phy mode, one of following: - USBPHY_INTERFACE_MODE_UTMI - USBPHY_INTERFACE_MODE_UTMIW

role_sw usb_role_switch handle

role_switch_default_mode default operation mode of controller while usb role is USB_ROLE_NONE.

fladj frame length adjustment

irq_gadget peripheral controller's IRQ number

otg_irq IRQ number for OTG IRQs

current_otg_role current role of operation while using the OTG block

desired_otg_role desired role of operation while using the OTG block

otg_restart_host flag that OTG controller needs to restart host

nr_scratch number of scratch buffers

u1u2 only used on revisions <1.83a for workaround

maximum_speed maximum speed requested (mainly for testing purposes)

ip controller's ID

revision controller's version of an IP

version_type VERSIONTYPE register contents, a sub release of a revision

ep0_next_event hold the next expected event

ep0state state of endpoint zero

link_state link state

u2sel parameter from Set SEL request.

u2pel parameter from Set SEL request.

u1sel parameter from Set SEL request.

u1pel parameter from Set SEL request.

speed device speed (super, high, full, low)

num_eps number of endpoints

hwparams copy of hwparams registers

root debugfs root folder pointer

regset debugfs pointer to regdump file

dbg_lsp_select current debug lsp mux register selection

test_mode true when we're entering a USB test mode

test_mode_nr test feature selector

lpm_nyet_threshold LPM NYET response threshold

hird_threshold HIRD threshold

rx_thr_num_pkt_prd periodic ESS receive packet count

rx_max_burst_prd max periodic ESS receive burst size

tx_thr_num_pkt_prd periodic ESS transmit packet count

tx_max_burst_prd max periodic ESS transmit burst size

hsphy_interface "utmi" or "ulpi"

connected true when we're connected to a host, false otherwise

delayed_status true when gadget driver asks for delayed status

ep0_bounced true when we used bounce buffer

ep0_expect_in true when we expect a DATA IN transfer

has_hibernation true when dwc3 was configured with Hibernation

sysdev_is_parent true when dwc3 device has a parent driver

has_lpm_erratum true when core was configured with LPM Erratum. Note that there's now way for software to detect this in runtime.

is_utmi_l1_suspend the core asserts output signal 0 - utmi_sleep_n 1 - utmi_l1_suspend_n

is_fpga true when we are using the FPGA board

pending_events true when we have pending IRQs to be handled

pullups_connected true when Run/Stop bit is set

setup_packet_pending true when there's a Setup Packet in FIFO. Workaround

three_stage_setup set if we perform a three phase setup

dis_start_transfer_quirk set if start_transfer failure SW workaround is not needed for DWC_usb31 version 1.70a-ea06 and below

usb3_lpm_capable set if hadrware supports Link Power Management

usb2_lpm_disable set to disable usb2 lpm

disable_scramble_quirk set if we enable the disable scramble quirk

u2exit_lfps_quirk set if we enable u2exit lfps quirk

u2ss_inp3_quirk set if we enable P3 OK for U2/SS Inactive quirk

req_p1p2p3_quirk set if we enable request p1p2p3 quirk

del_p1p2p3_quirk set if we enable delay p1p2p3 quirk

del_phy_power_chg_quirk set if we enable delay phy power change quirk

lfps_filter_quirk set if we enable LFPS filter quirk

rx_detect_poll_quirk set if we enable rx_detect to polling lfps quirk

dis_u3_susphy_quirk set if we disable usb3 suspend phy

dis_u2_susphy_quirk set if we disable usb2 suspend phy

dis_enblslpm_quirk set if we clear enblslpm in GUSB2PHYCFG, disabling the suspend signal to the PHY.

dis_u1_entry_quirk set if link entering into U1 state needs to be disabled.

dis_u2_entry_quirk set if link entering into U2 state needs to be disabled.

dis_rxdet_inp3_quirk set if we disable Rx.Detect in P3

dis_u2_freeclk_exists_quirk set if we clear u2_freeclk_exists in GUSB2PHYCFG, specify that USB2 PHY doesn't provide a free-running PHY clock.

dis_del_phy_power_chg_quirk set if we disable delay phy power change quirk.

dis_tx_ipgap_linecheck_quirk set if we disable u2mac linestate check during HS transmit.

parkmode_disable_ss_quirk set if we need to disable all SuperSpeed instances in park mode.

tx_de_emphasis_quirk set if we enable Tx de-emphasis quirk

tx_de_emphasis Tx de-emphasis value 0 - -6dB de-emphasis 1 - -3.5dB de-emphasis 2 - No de-emphasis 3 - Reserved

dis_metastability_quirk set to disable metastability quirk.

imod_interval set the interrupt moderation interval in 250ns increments or 0 to disable.

param2 third parameter

param1 second parameter

param0 first parameter

struct dwc3_request * **next_request**(struct list_head * list)
gets the next request on the given list

Parameters

struct list_head * list the request list to operate on

Description

Caller should take care of locking. This function return NULL or the first request available on **list**.

void **dwc3_gadget_move_started_request**(struct dwc3_request * req)
move **req** to the started_list

Parameters

struct dwc3_request * req the request to be moved

Description

Caller should take care of locking. This function will move **req** from its current list to the endpoint's started_list.

void **dwc3_gadget_move_cancelled_request**(struct dwc3_request * req)
move **req** to the cancelled_list

Parameters

struct dwc3_request * req the request to be moved

Description

Caller should take care of locking. This function will move **req** from its current list to the endpoint's cancelled_list.

void **dwc3_gadget_ep_get_transfer_index**(struct dwc3_ep * dep)
Gets transfer index from HW

Parameters

struct dwc3_ep * dep dwc3 endpoint

Description

Caller should take care of locking. Returns the transfer resource index for a given endpoint.

void **dwc3_gadget_dctl_write_safe**(struct dwc3 * dwc, u32 value)
write to DCTL safe from link state change

Parameters

struct dwc3 * dwc pointer to our context structure

u32 value value to write to DCTL

Description

Use this function when doing read-modify-write to DCTL. It will not send link state change request.

int **dwc3_gadget_set_test_mode**(struct dwc3 * dwc, int mode)
enables usb2 test modes

Parameters

struct dwc3 * dwc pointer to our context structure

int mode the mode to set (J, K SE0 NAK, Force Enable)

Description

Caller should take care of locking. This function will return 0 on success or -EINVAL if wrong Test Selector is passed.

int **dwc3_gadget_get_link_state**(struct dwc3 * dwc)
gets current state of usb link

Parameters

struct dwc3 * dwc pointer to our context structure

Description

Caller should take care of locking. This function will return the link state on success (>= 0) or -ETIMEDOUT.

int **dwc3_gadget_set_link_state**(struct dwc3 * dwc, enum dwc3_link_state state)
sets usb link to a particular state

Parameters

struct dwc3 * dwc pointer to our context structure

enum dwc3_link_state state the state to put link into

Description

Caller should take care of locking. This function will return 0 on success or -ETIMEDOUT.

void **dwc3_ep_inc_trb**(u8 * index)
increment a trb index.

Parameters

u8 * index Pointer to the TRB index to increment.

Description

The index should never point to the link TRB. After incrementing, if it is point to the link TRB, wrap around to the beginning. The link TRB is always at the last TRB entry.

void **dwc3_ep_inc_enq**(struct dwc3_ep * dep)
increment endpoint's enqueue pointer

Parameters

struct dwc3_ep * dep The endpoint whose enqueue pointer we're incrementing

void **dwc3_ep_inc_deq**(struct dwc3_ep * dep)
increment endpoint's dequeue pointer

Parameters

struct dwc3_ep * dep The endpoint whose enqueue pointer we're incrementing

void **dwc3_gadget_giveback**(struct dwc3_ep * dep, struct dwc3_request * req, int status)
call struct usb_request's ->complete callback

Parameters

struct dwc3_ep * dep The endpoint to whom the request belongs to

struct dwc3_request * req The request we' re giving back

int status completion code for the request

Description

Must be called with controller' s lock held and interrupts disabled. This function will unmap **req** and call its ->complete() callback to notify upper layers that it has completed.

int **dwc3_send_gadget_generic_command**(struct dwc3 * dwc, unsigned cmd, u32 param)
issue a generic command for the controller

Parameters

struct dwc3 * dwc pointer to the controller context

unsigned cmd the command to be issued

u32 param command parameter

Description

Caller should take care of locking. Issue **cmd** with a given **param** to **dwc** and wait for its completion.

int **dwc3_send_gadget_ep_cmd**(struct dwc3_ep * dep, unsigned cmd, struct dwc3_gadget_ep_cmd_params * params)
issue an endpoint command

Parameters

struct dwc3_ep * dep the endpoint to which the command is going to be issued

unsigned cmd the command to be issued

struct dwc3_gadget_ep_cmd_params * params parameters to the command

Description

Caller should handle locking. This function will issue **cmd** with given **params** to **dep** and wait for its completion.

int **dwc3_gadget_start_config**(struct dwc3_ep * dep)
configure ep resources

Parameters

struct dwc3_ep * dep endpoint that is being enabled

Description

Issue a DWC3_DEPCMD_DEPSTARTCFG command to **dep**. After the command' s completion, it will set Transfer Resource for all available endpoints.

The assignment of transfer resources cannot perfectly follow the data book due to the fact that the controller driver does not have all knowledge of the configuration in advance. It is given this information piecemeal by the composite gadget framework after every SET_CONFIGURATION and SET_INTERFACE. Trying to follow

the databook programming model in this scenario can cause errors. For two reasons:

1) The databook says to do DWC3_DEPCMD_DEPSTARTCFG for every USB_REQ_SET_CONFIGURATION and USB_REQ_SET_INTERFACE (8.1.5). This is incorrect in the scenario of multiple interfaces.

2) The databook does not mention doing more DWC3_DEPCMD_DEPXFERCFG for new endpoint on alt setting (8.1.6).

The following simplified method is used instead:

All hardware endpoints can be assigned a transfer resource and this setting will stay persistent until either a core reset or hibernation. So whenever we do a DWC3_DEPCMD_DEPSTARTCFG``(0) we can go ahead and do ``DWC3_DEPCMD_DEPXFERCFG for every hardware endpoint as well. We are guaranteed that there are as many transfer resources as endpoints.

This function is called for each endpoint when it is being enabled but is triggered only when called for EP0-out, which always happens first, and which should only happen in one of the above conditions.

int **__dwc3_gadget_ep_enable**(struct dwc3_ep * dep, unsigned int action)
initializes a hw endpoint

Parameters

struct dwc3_ep * dep endpoint to be initialized

unsigned int action one of INIT, MODIFY or RESTORE

Description

Caller should take care of locking. Execute all necessary commands to initialize a HW endpoint so it can be used by a gadget driver.

int **__dwc3_gadget_ep_disable**(struct dwc3_ep * dep)
disables a hw endpoint

Parameters

struct dwc3_ep * dep the endpoint to disable

Description

This function undoes what __dwc3_gadget_ep_enable did and also removes requests which are currently being processed by the hardware and those which are not yet scheduled.

Caller should take care of locking.

struct dwc3_trb * **dwc3_ep_prev_trb**(struct dwc3_ep * dep, u8 index)
returns the previous TRB in the ring

Parameters

struct dwc3_ep * dep The endpoint with the TRB ring

u8 index The index of the current TRB in the ring

Description

Returns the TRB prior to the one pointed to by the index. If the index is 0, we will wrap backwards, skip the link TRB, and return the one just before that.

void **dwc3_prepare_one_trb**(struct dwc3_ep * dep, struct dwc3_request * req, unsigned chain, unsigned node)
setup one TRB from one request

Parameters

struct dwc3_ep * dep endpoint for which this request is prepared

struct dwc3_request * req dwc3_request pointer

unsigned chain should this TRB be chained to the next?

unsigned node only for isochronous endpoints. First TRB needs different type.

int **dwc3_gadget_start_isoc_quirk**(struct dwc3_ep * dep)
workaround invalid frame number

Parameters

struct dwc3_ep * dep isoc endpoint

Description

This function tests for the correct combination of BIT[15:14] from the 16-bit microframe number reported by the XferNotReady event for the future frame number to start the isoc transfer.

In DWC_usb31 version 1.70a-ea06 and prior, for highspeed and fullspeed isochronous IN, BIT[15:14] of the 16-bit microframe number reported by the XferNotReady event are invalid. The driver uses this number to schedule the isochronous transfer and passes it to the START TRANSFER command. Because this number is invalid, the command may fail. If BIT[15:14] matches the internal 16-bit microframe, the START TRANSFER command will pass and the transfer will start at the scheduled time, if it is off by 1, the command will still pass, but the transfer will start 2 seconds in the future. For all other conditions, the START TRANSFER command will fail with bus-expiry.

In order to workaround this issue, we can test for the correct combination of BIT[15:14] by sending START TRANSFER commands with different values of BIT[15:14]: ‘b00, ‘b01, ‘b10, and ‘b11. Each combination is 2^14 uframe apart (or 2 seconds). 4 seconds into the future will result in a bus-expiry status. As the result, within the 4 possible combinations for BIT[15:14], there will be 2 successful and 2 failure START COMMAND status. One of the 2 successful command status will result in a 2-second delay start. The smaller BIT[15:14] value is the correct combination.

Since there are only 4 outcomes and the results are ordered, we can simply test 2 START TRANSFER commands with BIT[15:14] combinations ‘b00 and ‘b01 to deduce the smaller successful combination.

Let test0 = test status for combination ‘b00 and test1 = test status for ‘b01 of BIT[15:14]. The correct combination is as follow:

if test0 fails and test1 passes, BIT[15:14] is ‘b01 if test0 fails and test1 fails, BIT[15:14] is ‘b10 if test0 passes and test1 fails, BIT[15:14] is ‘b11 if test0 passes and test1 passes, BIT[15:14] is ‘b00

Synopsys STAR 9001202023: Wrong microframe number for isochronous IN endpoints.

void **dwc3_gadget_setup_nump**(struct dwc3 * dwc)
calculate and initialize NUMP field of DWC3_DCFG

Parameters

struct dwc3 * dwc pointer to our context structure

Description

The following looks like complex but it's actually very simple. In order to calculate the number of packets we can burst at once on OUT transfers, we're gonna use RxFIFO size.

To calculate RxFIFO size we need two numbers: MDWIDTH = size, in bits, of the internal memory bus RAM2_DEPTH = depth, in MDWIDTH, of internal RAM2 (where RxFIFO sits)

Given these two numbers, the formula is simple:

RxFIFO Size = (RAM2_DEPTH * MDWIDTH / 8) - 24 - 16;

24 bytes is for 3x SETUP packets 16 bytes is a clock domain crossing tolerance

Given RxFIFO Size, NUMP = RxFIFOSize / 1024;

int **dwc3_gadget_init**(struct dwc3 * dwc)
initializes gadget related registers

Parameters

struct dwc3 * dwc pointer to our controller context structure

Description

Returns 0 on success otherwise negative errno.

DWC3_DEFAULT_AUTOSUSPEND_DELAY()
DesignWare USB3 DRD Controller Core file

Parameters

Description

Copyright (C) 2010-2011 Texas Instruments Incorporated - http://www.ti.com

Authors: Felipe Balbi <balbiti.com**>,** Sebastian Andrzej Siewior <bigeasy**linutronix.de**>

int **dwc3_get_dr_mode**(struct dwc3 * dwc)
Validates and sets dr_mode

Parameters

struct dwc3 * dwc pointer to our context structure

int **dwc3_core_soft_reset**(struct dwc3 * dwc)
Issues core soft reset and PHY reset

Parameters

struct dwc3 * dwc pointer to our context structure

void **dwc3_free_one_event_buffer**(struct dwc3 * dwc, struct dwc3_event_buffer * evt)
Frees one event buffer

Parameters

struct dwc3 * dwc Pointer to our controller context structure

struct dwc3_event_buffer * evt Pointer to event buffer to be freed

struct dwc3_event_buffer * **dwc3_alloc_one_event_buffer**(struct dwc3 * dwc, unsigned length)
Allocates one event buffer structure

Parameters

struct dwc3 * dwc Pointer to our controller context structure

unsigned length size of the event buffer

Description

Returns a pointer to the allocated event buffer structure on success otherwise ERR_PTR(errno).

void **dwc3_free_event_buffers**(struct dwc3 * dwc)
frees all allocated event buffers

Parameters

struct dwc3 * dwc Pointer to our controller context structure

int **dwc3_alloc_event_buffers**(struct dwc3 * dwc, unsigned length)
Allocates **num** event buffers of size **length**

Parameters

struct dwc3 * dwc pointer to our controller context structure

unsigned length size of event buffer

Description

Returns 0 on success otherwise negative errno. In the error case, dwc may contain some buffers allocated but not all which were requested.

int **dwc3_event_buffers_setup**(struct dwc3 * dwc)
setup our allocated event buffers

Parameters

struct dwc3 * dwc pointer to our controller context structure

Description

Returns 0 on success otherwise negative errno.

int **dwc3_phy_setup**(struct dwc3 * dwc)
Configure USB PHY Interface of DWC3 Core

Parameters

struct dwc3 * dwc Pointer to our controller context structure

Description

Returns 0 on success. The USB PHY interfaces are configured but not initialized. The PHY interfaces and the PHYs get initialized together with the core in dwc3_core_init.

int **dwc3_core_init**(struct dwc3 * dwc)
Low-level initialization of DWC3 Core

Parameters

struct dwc3 * dwc Pointer to our controller context structure

Description

Returns 0 on success otherwise negative errno.

20.14 Writing a MUSB Glue Layer

Author Apelete Seketeli

20.14.1 Introduction

The Linux MUSB subsystem is part of the larger Linux USB subsystem. It provides support for embedded USB Device Controllers (UDC) that do not use Universal Host Controller Interface (UHCI) or Open Host Controller Interface (OHCI).

Instead, these embedded UDC rely on the USB On-the-Go (OTG) specification which they implement at least partially. The silicon reference design used in most cases is the Multipoint USB Highspeed Dual-Role Controller (MUSB HDRC) found in the Mentor Graphics Inventra™ design.

As a self-taught exercise I have written an MUSB glue layer for the Ingenic JZ4740 SoC, modelled after the many MUSB glue layers in the kernel source tree. This layer can be found at `drivers/usb/musb/jz4740.c`. In this documentation I will walk through the basics of the `jz4740.c` glue layer, explaining the different pieces and what needs to be done in order to write your own device glue layer.

20.14.2 Linux MUSB Basics

To get started on the topic, please read USB On-the-Go Basics (see Resources) which provides an introduction of USB OTG operation at the hardware level. A couple of wiki pages by Texas Instruments and Analog Devices also provide an overview of the Linux kernel MUSB configuration, albeit focused on some specific devices provided by these companies. Finally, getting acquainted with the USB specification at USB home page may come in handy, with practical instance provided through the Writing USB Device Drivers documentation (again, see Resources).

Linux USB stack is a layered architecture in which the MUSB controller hardware sits at the lowest. The MUSB controller driver abstract the MUSB controller hardware to the Linux USB stack:

```
    ------------------------
    |                      | <------- drivers/usb/gadget
    | Linux USB Core Stack | <------- drivers/usb/host
    |                      | <------- drivers/usb/core
    ------------------------
               ↕
   --------------------------
   |                        | <------ drivers/usb/musb/musb_gadget.c
   | MUSB Controller driver | <------ drivers/usb/musb/musb_host.c
   |                        | <------ drivers/usb/musb/musb_core.c
   --------------------------
               ↕
--------------------------------
| MUSB Platform Specific Driver |
|                               | <-- drivers/usb/musb/jz4740.c
|       aka "Glue Layer"        |
--------------------------------
               ↕
--------------------------------
|   MUSB Controller Hardware    |
--------------------------------
```

As outlined above, the glue layer is actually the platform specific code sitting in between the controller driver and the controller hardware.

Just like a Linux USB driver needs to register itself with the Linux USB subsystem, the MUSB glue layer needs first to register itself with the MUSB controller driver. This will allow the controller driver to know about which device the glue layer supports and which functions to call when a supported device is detected or released; remember we are talking about an embedded controller chip here, so no insertion or removal at run-time.

All of this information is passed to the MUSB controller driver through a `platform_driver` structure defined in the glue layer as:

```
static struct platform_driver jz4740_driver = {
    .probe      = jz4740_probe,
    .remove     = jz4740_remove,
    .driver     = {
        .name   = "musb-jz4740",
    },
};
```

The probe and remove function pointers are called when a matching device is detected and, respectively, released. The name string describes the device supported by this glue layer. In the current case it matches a platform_device structure declared in `arch/mips/jz4740/platform.c`. Note that we are not using device tree bindings here.

In order to register itself to the controller driver, the glue layer goes through a few steps, basically allocating the controller hardware resources and initialising a couple of circuits. To do so, it needs to keep track of the information used throughout these steps. This is done by defining a private `jz4740_glue` structure:

```
struct jz4740_glue {
```

(continues on next page)

(continued from previous page)

```
    struct device           *dev;
    struct platform_device  *musb;
    struct clk      *clk;
};
```

The dev and musb members are both device structure variables. The first one holds generic information about the device, since it's the basic device structure, and the latter holds information more closely related to the subsystem the device is registered to. The clk variable keeps information related to the device clock operation.

Let's go through the steps of the probe function that leads the glue layer to register itself to the controller driver.

Note: For the sake of readability each function will be split in logical parts, each part being shown as if it was independent from the others.

```
static int jz4740_probe(struct platform_device *pdev)
{
    struct platform_device      *musb;
    struct jz4740_glue      *glue;
    struct clk                      *clk;
    int             ret;

    glue = devm_kzalloc(&pdev->dev, sizeof(*glue), GFP_KERNEL);
    if (!glue)
        return -ENOMEM;

    musb = platform_device_alloc("musb-hdrc", PLATFORM_DEVID_AUTO);
    if (!musb) {
        dev_err(&pdev->dev, "failed to allocate musb device\n");
        return -ENOMEM;
    }

    clk = devm_clk_get(&pdev->dev, "udc");
    if (IS_ERR(clk)) {
        dev_err(&pdev->dev, "failed to get clock\n");
        ret = PTR_ERR(clk);
        goto err_platform_device_put;
    }

    ret = clk_prepare_enable(clk);
    if (ret) {
        dev_err(&pdev->dev, "failed to enable clock\n");
        goto err_platform_device_put;
    }

    musb->dev.parent        = &pdev->dev;

    glue->dev           = &pdev->dev;
    glue->musb          = musb;
    glue->clk           = clk;
```

(continues on next page)

(continued from previous page)

```
    return 0;

err_platform_device_put:
    platform_device_put(musb);
    return ret;
}
```

The first few lines of the probe function allocate and assign the glue, musb and clk variables. The GFP_KERNEL flag (line 8) allows the allocation process to sleep and wait for memory, thus being usable in a locking situation. The PLATFORM_DEVID_AUTO flag (line 12) allows automatic allocation and management of device IDs in order to avoid device namespace collisions with explicit IDs. With devm_clk_get() (line 18) the glue layer allocates the clock – the devm_ prefix indicates that clk_get() is managed: it automatically frees the allocated clock resource data when the device is released – and enable it.

Then comes the registration steps:

```
static int jz4740_probe(struct platform_device *pdev)
{
    struct musb_hdrc_platform_data  *pdata = &jz4740_musb_platform_data;

    pdata->platform_ops     = &jz4740_musb_ops;

    platform_set_drvdata(pdev, glue);

    ret = platform_device_add_resources(musb, pdev->resource,
                        pdev->num_resources);
    if (ret) {
        dev_err(&pdev->dev, "failed to add resources\n");
        goto err_clk_disable;
    }

    ret = platform_device_add_data(musb, pdata, sizeof(*pdata));
    if (ret) {
        dev_err(&pdev->dev, "failed to add platform_data\n");
        goto err_clk_disable;
    }

    return 0;

err_clk_disable:
    clk_disable_unprepare(clk);
err_platform_device_put:
    platform_device_put(musb);
    return ret;
}
```

The first step is to pass the device data privately held by the glue layer on to the controller driver through platform_set_drvdata() (line 7). Next is passing on the device resources information, also privately held at that point, through platform_device_add_resources() (line 9).

Finally comes passing on the platform specific data to the controller driver (line 16). Platform data will be discussed in Device Platform Data, but here we are look-

ing at the `platform_ops` function pointer (line 5) in `musb_hdrc_platform_data` structure (line 3). This function pointer allows the MUSB controller driver to know which function to call for device operation:

```
static const struct musb_platform_ops jz4740_musb_ops = {
    .init       = jz4740_musb_init,
    .exit       = jz4740_musb_exit,
};
```

Here we have the minimal case where only init and exit functions are called by the controller driver when needed. Fact is the JZ4740 MUSB controller is a basic controller, lacking some features found in other controllers, otherwise we may also have pointers to a few other functions like a power management function or a function to switch between OTG and non-OTG modes, for instance.

At that point of the registration process, the controller driver actually calls the init function:

```
static int jz4740_musb_init(struct musb *musb)
{
    musb->xceiv = usb_get_phy(USB_PHY_TYPE_USB2);
    if (!musb->xceiv) {
        pr_err("HS UDC: no transceiver configured\n");
        return -ENODEV;
    }

    /* Silicon does not implement ConfigData register.
     * Set dyn_fifo to avoid reading EP config from hardware.
     */
    musb->dyn_fifo = true;

    musb->isr = jz4740_musb_interrupt;

    return 0;
}
```

The goal of `jz4740_musb_init()` is to get hold of the transceiver driver data of the MUSB controller hardware and pass it on to the MUSB controller driver, as usual. The transceiver is the circuitry inside the controller hardware responsible for sending/receiving the USB data. Since it is an implementation of the physical layer of the OSI model, the transceiver is also referred to as PHY.

Getting hold of the `MUSB PHY` driver data is done with `usb_get_phy()` which returns a pointer to the structure containing the driver instance data. The next couple of instructions (line 12 and 14) are used as a quirk and to setup IRQ handling respectively. Quirks and IRQ handling will be discussed later in Device Quirks and Handling IRQs

```
static int jz4740_musb_exit(struct musb *musb)
{
    usb_put_phy(musb->xceiv);

    return 0;
}
```

Acting as the counterpart of init, the exit function releases the MUSB PHY driver

when the controller hardware itself is about to be released.

Again, note that init and exit are fairly simple in this case due to the basic set of features of the JZ4740 controller hardware. When writing an musb glue layer for a more complex controller hardware, you might need to take care of more processing in those two functions.

Returning from the init function, the MUSB controller driver jumps back into the probe function:

```
static int jz4740_probe(struct platform_device *pdev)
{
    ret = platform_device_add(musb);
    if (ret) {
        dev_err(&pdev->dev, "failed to register musb device\n");
        goto err_clk_disable;
    }

    return 0;

err_clk_disable:
    clk_disable_unprepare(clk);
err_platform_device_put:
    platform_device_put(musb);
    return ret;
}
```

This is the last part of the device registration process where the glue layer adds the controller hardware device to Linux kernel device hierarchy: at this stage, all known information about the device is passed on to the Linux USB core stack:

```
static int jz4740_remove(struct platform_device *pdev)
{
    struct jz4740_glue  *glue = platform_get_drvdata(pdev);

    platform_device_unregister(glue->musb);
    clk_disable_unprepare(glue->clk);

    return 0;
}
```

Acting as the counterpart of probe, the remove function unregister the MUSB controller hardware (line 5) and disable the clock (line 6), allowing it to be gated.

20.14.3 Handling IRQs

Additionally to the MUSB controller hardware basic setup and registration, the glue layer is also responsible for handling the IRQs:

```
static irqreturn_t jz4740_musb_interrupt(int irq, void *__hci)
{
    unsigned long   flags;
    irqreturn_t     retval = IRQ_NONE;
    struct musb     *musb = __hci;
```

(continues on next page)

(continued from previous page)

```
    spin_lock_irqsave(&musb->lock, flags);

    musb->int_usb = musb_readb(musb->mregs, MUSB_INTRUSB);
    musb->int_tx = musb_readw(musb->mregs, MUSB_INTRTX);
    musb->int_rx = musb_readw(musb->mregs, MUSB_INTRRX);

    /*
     * The controller is gadget only, the state of the host mode␣
↪IRQ bits is
     * undefined. Mask them to make sure that the musb driver␣
↪core will
     * never see them set
     */
    musb->int_usb &= MUSB_INTR_SUSPEND | MUSB_INTR_RESUME |
        MUSB_INTR_RESET | MUSB_INTR_SOF;

    if (musb->int_usb || musb->int_tx || musb->int_rx)
        retval = musb_interrupt(musb);

    spin_unlock_irqrestore(&musb->lock, flags);

    return retval;
}
```

Here the glue layer mostly has to read the relevant hardware registers and pass their values on to the controller driver which will handle the actual event that triggered the IRQ.

The interrupt handler critical section is protected by the `spin_lock_irqsave()` and counterpart `spin_unlock_irqrestore()` functions (line 7 and 24 respectively), which prevent the interrupt handler code to be run by two different threads at the same time.

Then the relevant interrupt registers are read (line 9 to 11):

- `MUSB_INTRUSB`: indicates which USB interrupts are currently active,
- `MUSB_INTRTX`: indicates which of the interrupts for TX endpoints are currently active,
- `MUSB_INTRRX`: indicates which of the interrupts for TX endpoints are currently active.

Note that `musb_readb()` is used to read 8-bit registers at most, while `musb_readw()` allows us to read at most 16-bit registers. There are other functions that can be used depending on the size of your device registers. See `musb_io.h` for more information.

Instruction on line 18 is another quirk specific to the JZ4740 USB device controller, which will be discussed later in Device Quirks.

The glue layer still needs to register the IRQ handler though. Remember the instruction on line 14 of the init function:

```
static int jz4740_musb_init(struct musb *musb)
{
```

(continues on next page)

(continued from previous page)

```
    musb->isr = jz4740_musb_interrupt;

    return 0;
}
```

This instruction sets a pointer to the glue layer IRQ handler function, in order for the controller hardware to call the handler back when an IRQ comes from the controller hardware. The interrupt handler is now implemented and registered.

20.14.4 Device Platform Data

In order to write an MUSB glue layer, you need to have some data describing the hardware capabilities of your controller hardware, which is called the platform data.

Platform data is specific to your hardware, though it may cover a broad range of devices, and is generally found somewhere in the `arch/` directory, depending on your device architecture.

For instance, platform data for the JZ4740 SoC is found in `arch/mips/jz4740/platform.c`. In the `platform.c` file each device of the JZ4740 SoC is described through a set of structures.

Here is the part of `arch/mips/jz4740/platform.c` that covers the USB Device Controller (UDC):

```
/* USB Device Controller */
struct platform_device jz4740_udc_xceiv_device = {
    .name = "usb_phy_gen_xceiv",
    .id   = 0,
};

static struct resource jz4740_udc_resources[] = {
    [0] = {
        .start = JZ4740_UDC_BASE_ADDR,
        .end   = JZ4740_UDC_BASE_ADDR + 0x10000 - 1,
        .flags = IORESOURCE_MEM,
    },
    [1] = {
        .start = JZ4740_IRQ_UDC,
        .end   = JZ4740_IRQ_UDC,
        .flags = IORESOURCE_IRQ,
        .name  = "mc",
    },
};

struct platform_device jz4740_udc_device = {
    .name = "musb-jz4740",
    .id   = -1,
    .dev  = {
        .dma_mask          = &jz4740_udc_device.dev.coherent_dma_
↪mask,
        .coherent_dma_mask = DMA_BIT_MASK(32),
    },
```

(continues on next page)

(continued from previous page)

```
    .num_resources = ARRAY_SIZE(jz4740_udc_resources),
    .resource      = jz4740_udc_resources,
};
```

The `jz4740_udc_xceiv_device` platform device structure (line 2) describes the UDC transceiver with a name and id number.

At the time of this writing, note that `usb_phy_gen_xceiv` is the specific name to be used for all transceivers that are either built-in with reference USB IP or autonomous and doesn't require any PHY programming. You will need to set `CONFIG_NOP_USB_XCEIV=y` in the kernel configuration to make use of the corresponding transceiver driver. The id field could be set to -1 (equivalent to `PLATFORM_DEVID_NONE`), -2 (equivalent to `PLATFORM_DEVID_AUTO`) or start with 0 for the first device of this kind if we want a specific id number.

The `jz4740_udc_resources` resource structure (line 7) defines the UDC registers base addresses.

The first array (line 9 to 11) defines the UDC registers base memory addresses: start points to the first register memory address, end points to the last register memory address and the flags member defines the type of resource we are dealing with. So `IORESOURCE_MEM` is used to define the registers memory addresses. The second array (line 14 to 17) defines the UDC IRQ registers addresses. Since there is only one IRQ register available for the JZ4740 UDC, start and end point at the same address. The `IORESOURCE_IRQ` flag tells that we are dealing with IRQ resources, and the name `mc` is in fact hard-coded in the MUSB core in order for the controller driver to retrieve this IRQ resource by querying it by its name.

Finally, the `jz4740_udc_device` platform device structure (line 21) describes the UDC itself.

The `musb-jz4740` name (line 22) defines the MUSB driver that is used for this device; remember this is in fact the name that we used in the `jz4740_driver` platform driver structure in Linux MUSB Basics. The id field (line 23) is set to -1 (equivalent to `PLATFORM_DEVID_NONE`) since we do not need an id for the device: the MUSB controller driver was already set to allocate an automatic id in Linux MUSB Basics. In the dev field we care for DMA related information here. The `dma_mask` field (line 25) defines the width of the DMA mask that is going to be used, and `coherent_dma_mask` (line 26) has the same purpose but for the `alloc_coherent` DMA mappings: in both cases we are using a 32 bits mask. Then the resource field (line 29) is simply a pointer to the resource structure defined before, while the `num_resources` field (line 28) keeps track of the number of arrays defined in the resource structure (in this case there were two resource arrays defined before).

With this quick overview of the UDC platform data at the `arch/` level now done, let's get back to the MUSB glue layer specific platform data in `drivers/usb/musb/jz4740.c`:

```
static struct musb_hdrc_config jz4740_musb_config = {
    /* Silicon does not implement USB OTG. */
    .multipoint = 0,
    /* Max EPs scanned, driver will decide which EP can be used.␣
↪*/
```

(continues on next page)

(continued from previous page)

```
    .num_eps    = 4,
    /* RAMbits needed to configure EPs from table */
    .ram_bits   = 9,
    .fifo_cfg = jz4740_musb_fifo_cfg,
    .fifo_cfg_size = ARRAY_SIZE(jz4740_musb_fifo_cfg),
};

static struct musb_hdrc_platform_data jz4740_musb_platform_data =
↪{
    .mode   = MUSB_PERIPHERAL,
    .config = &jz4740_musb_config,
};
```

First the glue layer configures some aspects of the controller driver operation related to the controller hardware specifics. This is done through the `jz4740_musb_config` `musb_hdrc_config` structure.

Defining the OTG capability of the controller hardware, the multipoint member (line 3) is set to 0 (equivalent to false) since the JZ4740 UDC is not OTG compatible. Then `num_eps` (line 5) defines the number of USB endpoints of the controller hardware, including endpoint 0: here we have 3 endpoints + endpoint 0. Next is `ram_bits` (line 7) which is the width of the RAM address bus for the MUSB controller hardware. This information is needed when the controller driver cannot automatically configure endpoints by reading the relevant controller hardware registers. This issue will be discussed when we get to device quirks in Device Quirks. Last two fields (line 8 and 9) are also about device quirks: `fifo_cfg` points to the USB endpoints configuration table and `fifo_cfg_size` keeps track of the size of the number of entries in that configuration table. More on that later in Device Quirks.

Then this configuration is embedded inside `jz4740_musb_platform_data` `musb_hdrc_platform_data` structure (line 11): config is a pointer to the configuration structure itself, and mode tells the controller driver if the controller hardware may be used as `MUSB_HOST` only, `MUSB_PERIPHERAL` only or `MUSB_OTG` which is a dual mode.

Remember that `jz4740_musb_platform_data` is then used to convey platform data information as we have seen in the probe function in Linux MUSB Basics.

20.14.5 Device Quirks

Completing the platform data specific to your device, you may also need to write some code in the glue layer to work around some device specific limitations. These quirks may be due to some hardware bugs, or simply be the result of an incomplete implementation of the USB On-the-Go specification.

The JZ4740 UDC exhibits such quirks, some of which we will discuss here for the sake of insight even though these might not be found in the controller hardware you are working on.

Let's get back to the init function first:

```
static int jz4740_musb_init(struct musb *musb)
{
    musb->xceiv = usb_get_phy(USB_PHY_TYPE_USB2);
    if (!musb->xceiv) {
        pr_err("HS UDC: no transceiver configured\n");
        return -ENODEV;
    }

    /* Silicon does not implement ConfigData register.
     * Set dyn_fifo to avoid reading EP config from hardware.
     */
    musb->dyn_fifo = true;

    musb->isr = jz4740_musb_interrupt;

    return 0;
}
```

Instruction on line 12 helps the MUSB controller driver to work around the fact that the controller hardware is missing registers that are used for USB endpoints configuration.

Without these registers, the controller driver is unable to read the endpoints configuration from the hardware, so we use line 12 instruction to bypass reading the configuration from silicon, and rely on a hard-coded table that describes the endpoints configuration instead:

```
static struct musb_fifo_cfg jz4740_musb_fifo_cfg[] = {
    { .hw_ep_num = 1, .style = FIFO_TX, .maxpacket = 512, },
    { .hw_ep_num = 1, .style = FIFO_RX, .maxpacket = 512, },
    { .hw_ep_num = 2, .style = FIFO_TX, .maxpacket = 64, },
};
```

Looking at the configuration table above, we see that each endpoints is described by three fields: `hw_ep_num` is the endpoint number, style is its direction (either `FIFO_TX` for the controller driver to send packets in the controller hardware, or `FIFO_RX` to receive packets from hardware), and maxpacket defines the maximum size of each data packet that can be transmitted over that endpoint. Reading from the table, the controller driver knows that endpoint 1 can be used to send and receive USB data packets of 512 bytes at once (this is in fact a bulk in/out endpoint), and endpoint 2 can be used to send data packets of 64 bytes at once (this is in fact an interrupt endpoint).

Note that there is no information about endpoint 0 here: that one is implemented by default in every silicon design, with a predefined configuration according to the USB specification. For more examples of endpoint configuration tables, see `musb_core.c`.

Let's now get back to the interrupt handler function:

```
static irqreturn_t jz4740_musb_interrupt(int irq, void *__hci)
{
    unsigned long   flags;
    irqreturn_t     retval = IRQ_NONE;
    struct musb     *musb = __hci;
```

(continues on next page)

(continued from previous page)

```
    spin_lock_irqsave(&musb->lock, flags);

    musb->int_usb = musb_readb(musb->mregs, MUSB_INTRUSB);
    musb->int_tx = musb_readw(musb->mregs, MUSB_INTRTX);
    musb->int_rx = musb_readw(musb->mregs, MUSB_INTRRX);

    /*
     * The controller is gadget only, the state of the host mode␣
↪IRQ bits is
     * undefined. Mask them to make sure that the musb driver␣
↪core will
     * never see them set
     */
    musb->int_usb &= MUSB_INTR_SUSPEND | MUSB_INTR_RESUME |
        MUSB_INTR_RESET | MUSB_INTR_SOF;

    if (musb->int_usb || musb->int_tx || musb->int_rx)
        retval = musb_interrupt(musb);

    spin_unlock_irqrestore(&musb->lock, flags);

    return retval;
}
```

Instruction on line 18 above is a way for the controller driver to work around the fact that some interrupt bits used for USB host mode operation are missing in the `MUSB_INTRUSB` register, thus left in an undefined hardware state, since this MUSB controller hardware is used in peripheral mode only. As a consequence, the glue layer masks these missing bits out to avoid parasite interrupts by doing a logical AND operation between the value read from `MUSB_INTRUSB` and the bits that are actually implemented in the register.

These are only a couple of the quirks found in the JZ4740 USB device controller. Some others were directly addressed in the MUSB core since the fixes were generic enough to provide a better handling of the issues for others controller hardware eventually.

20.14.6 Conclusion

Writing a Linux MUSB glue layer should be a more accessible task, as this documentation tries to show the ins and outs of this exercise.

The JZ4740 USB device controller being fairly simple, I hope its glue layer serves as a good example for the curious mind. Used with the current MUSB glue layers, this documentation should provide enough guidance to get started; should anything gets out of hand, the linux-usb mailing list archive is another helpful resource to browse through.

20.14.7 Acknowledgements

Many thanks to Lars-Peter Clausen and Maarten ter Huurne for answering my questions while I was writing the JZ4740 glue layer and for helping me out getting the code in good shape.

I would also like to thank the Qi-Hardware community at large for its cheerful guidance and support.

Writing USB Device Drivers

Texas Instruments USB Configuration Wiki Page: http://processors.wiki.ti.com/index.php/Usbgeneralpage

20.15 USB Type-C connector class

20.15.1 Introduction

The typec class is meant for describing the USB Type-C ports in a system to the user space in unified fashion. The class is designed to provide nothing else except the user space interface implementation in hope that it can be utilized on as many platforms as possible.

The platforms are expected to register every USB Type-C port they have with the class. In a normal case the registration will be done by a USB Type-C or PD PHY driver, but it may be a driver for firmware interface such as UCSI, driver for USB PD controller or even driver for Thunderbolt3 controller. This document considers the component registering the USB Type-C ports with the class as “port driver”.

On top of showing the capabilities, the class also offer user space control over the roles and alternate modes of ports, partners and cable plugs when the port driver is capable of supporting those features.

The class provides an API for the port drivers described in this document. The attributes are described in Documentation/ABI/testing/sysfs-class-typec.

20.15.2 User space interface

Every port will be presented as its own device under /sys/class/typec/. The first port will be named “port0”, the second “port1” and so on.

When connected, the partner will be presented also as its own device under /sys/class/typec/. The parent of the partner device will always be the port it is attached to. The partner attached to port “port0” will be named “port0-partner”. Full path to the device would be /sys/class/typec/port0/port0-partner/.

The cable and the two plugs on it may also be optionally presented as their own devices under /sys/class/typec/. The cable attached to the port “port0” port will be named port0-cable and the plug on the SOP Prime end (see USB Power Delivery Specification ch. 2.4) will be named “port0-plug0” and on the SOP Double Prime end “port0-plug1”. The parent of a cable will always be the port, and the parent of the cable plugs will always be the cable.

If the port, partner or cable plug supports Alternate Modes, every supported Alternate Mode SVID will have their own device describing them. Note that the Alternate Mode devices will not be attached to the typec class. The parent of an alternate mode will be the device that supports it, so for example an alternate mode of port0-partner will be presented under /sys/class/typec/port0-partner/. Every mode that is supported will have its own group under the Alternate Mode device named “mode<index>”, for example /sys/class/typec/port0/<alternate mode>/mode1/. The requests for entering/exiting a mode can be done with “active” attribute file in that group.

20.15.3 Driver API

Registering the ports

The port drivers will describe every Type-C port they control with struct typec_capability data structure, and register them with the following API:

struct typec_port * **typec_register_port**(struct device * parent, const struct typec_capability * cap)
Register a USB Type-C Port

Parameters

struct device * parent Parent device

const struct typec_capability * cap Description of the port

Description

Registers a device for USB Type-C Port described in **cap**.

Returns handle to the port on success or ERR_PTR on failure.

void **typec_unregister_port**(struct typec_port * port)
Unregister a USB Type-C Port

Parameters

struct typec_port * port The port to be unregistered

Description

Unregister device created with `typec_register_port()`.

When registering the ports, the prefer_role member in struct typec_capability deserves special notice. If the port that is being registered does not have initial role preference, which means the port does not execute Try.SNK or Try.SRC by default, the member must have value TYPEC_NO_PREFERRED_ROLE. Otherwise if the port executes Try.SNK by default, the member must have value TYPEC_DEVICE, and with Try.SRC the value must be TYPEC_HOST.

Registering Partners

After successful connection of a partner, the port driver needs to register the partner with the class. Details about the partner need to be described in struct typec_partner_desc. The class copies the details of the partner during registration. The class offers the following API for registering/unregistering partners.

struct typec_partner * **typec_register_partner**(struct typec_port * port, struct typec_partner_desc * desc)
Register a USB Type-C Partner

Parameters

struct typec_port * port The USB Type-C Port the partner is connected to

struct typec_partner_desc * desc Description of the partner

Description

Registers a device for USB Type-C Partner described in **desc**.

Returns handle to the partner on success or ERR_PTR on failure.

void **typec_unregister_partner**(struct typec_partner * partner)
Unregister a USB Type-C Partner

Parameters

struct typec_partner * partner The partner to be unregistered

Description

Unregister device created with `typec_register_partner()`.

The class will provide a handle to struct typec_partner if the registration was successful, or NULL.

If the partner is USB Power Delivery capable, and the port driver is able to show the result of Discover Identity command, the partner descriptor structure should include handle to struct usb_pd_identity instance. The class will then create a sysfs directory for the identity under the partner device. The result of Discover Identity command can then be reported with the following API:

int **typec_partner_set_identity**(struct typec_partner * partner)
Report result from Discover Identity command

Parameters

struct typec_partner * partner The partner updated identity values

Description

This routine is used to report that the result of Discover Identity USB power delivery command has become available.

Registering Cables

After successful connection of a cable that supports USB Power Delivery Structured VDM "Discover Identity", the port driver needs to register the cable and one or two plugs, depending if there is CC Double Prime controller present in the cable or not. So a cable capable of SOP Prime communication, but not SOP Double Prime communication, should only have one plug registered. For more information about SOP communication, please read chapter about it from the latest USB Power Delivery specification.

The plugs are represented as their own devices. The cable is registered first, followed by registration of the cable plugs. The cable will be the parent device for the plugs. Details about the cable need to be described in struct typec_cable_desc and about a plug in struct typec_plug_desc. The class copies the details during registration. The class offers the following API for registering/unregistering cables and their plugs:

struct typec_plug * **typec_register_plug**(struct typec_cable * cable, struct typec_plug_desc * desc)
Register a USB Type-C Cable Plug

Parameters

struct typec_cable * cable USB Type-C Cable with the plug

struct typec_plug_desc * desc Description of the cable plug

Description

Registers a device for USB Type-C Cable Plug described in **desc**. A USB Type-C Cable Plug represents a plug with electronics in it that can response to USB Power Delivery SOP Prime or SOP Double Prime packages.

Returns handle to the cable plug on success or ERR_PTR on failure.

void **typec_unregister_plug**(struct typec_plug * plug)
Unregister a USB Type-C Cable Plug

Parameters

struct typec_plug * plug The cable plug to be unregistered

Description

Unregister device created with `typec_register_plug()`.

struct typec_cable * **typec_register_cable**(struct typec_port * port, struct typec_cable_desc * desc)
Register a USB Type-C Cable

Parameters

struct typec_port * port The USB Type-C Port the cable is connected to

struct typec_cable_desc * desc Description of the cable

Description

Registers a device for USB Type-C Cable described in **desc**. The cable will be parent for the optional cable plug devises.

Returns handle to the cable on success or ERR_PTR on failure.

void **typec_unregister_cable**(struct typec_cable * cable)
Unregister a USB Type-C Cable

Parameters

struct typec_cable * cable The cable to be unregistered

Description

Unregister device created with `typec_register_cable()`.

The class will provide a handle to struct typec_cable and struct typec_plug if the registration is successful, or NULL if it isn't.

If the cable is USB Power Delivery capable, and the port driver is able to show the result of Discover Identity command, the cable descriptor structure should include handle to struct usb_pd_identity instance. The class will then create a sysfs directory for the identity under the cable device. The result of Discover Identity command can then be reported with the following API:

int **typec_cable_set_identity**(struct typec_cable * cable)
Report result from Discover Identity command

Parameters

struct typec_cable * cable The cable updated identity values

Description

This routine is used to report that the result of Discover Identity USB power delivery command has become available.

Notifications

When the partner has executed a role change, or when the default roles change during connection of a partner or cable, the port driver must use the following APIs to report it to the class:

void **typec_set_data_role**(struct typec_port * port, enum typec_data_role role)
Report data role change

Parameters

struct typec_port * port The USB Type-C Port where the role was changed

enum typec_data_role role The new data role

Description

This routine is used by the port drivers to report data role changes.

void **typec_set_pwr_role**(struct typec_port * port, enum typec_role role)
Report power role change

Parameters

struct typec_port * port The USB Type-C Port where the role was changed

enum typec_role role The new data role

Description

This routine is used by the port drivers to report power role changes.

void **typec_set_vconn_role**(struct typec_port * port, enum typec_role role)
Report VCONN source change

Parameters

struct typec_port * port The USB Type-C Port which VCONN role changed

enum typec_role role Source when **port** is sourcing VCONN, or Sink when it's not

Description

This routine is used by the port drivers to report if the VCONN source is changes.

void **typec_set_pwr_opmode**(struct typec_port * port, enum typec_pwr_opmode opmode)
Report changed power operation mode

Parameters

struct typec_port * port The USB Type-C Port where the mode was changed

enum typec_pwr_opmode opmode New power operation mode

Description

This routine is used by the port drivers to report changed power operation mode in **port**. The modes are USB (default), 1.5A, 3.0A as defined in USB Type-C specification, and "USB Power Delivery" when the power levels are negotiated with methods defined in USB Power Delivery specification.

Alternate Modes

USB Type-C ports, partners and cable plugs may support Alternate Modes. Each Alternate Mode will have identifier called SVID, which is either a Standard ID given by USB-IF or vendor ID, and each supported SVID can have 1 - 6 modes. The class provides struct typec_mode_desc for describing individual mode of a SVID, and struct typec_altmode_desc which is a container for all the supported modes.

Ports that support Alternate Modes need to register each SVID they support with the following API:

struct typec_altmode * **typec_port_register_altmode**(struct typec_port * port, const struct typec_altmode_desc * desc)

Register USB Type-C Port Alternate Mode

Parameters

struct typec_port * port USB Type-C Port that supports the alternate mode

const struct typec_altmode_desc * desc Description of the alternate mode

Description

This routine is used to register an alternate mode that **port** is capable of supporting.

Returns handle to the alternate mode on success or ERR_PTR on failure.

If a partner or cable plug provides a list of SVIDs as response to USB Power Delivery Structured VDM Discover SVIDs message, each SVID needs to be registered.

API for the partners:

struct typec_altmode * **typec_partner_register_altmode**(struct typec_partner * partner, const struct typec_altmode_desc * desc)

Register USB Type-C Partner Alternate Mode

Parameters

struct typec_partner * partner USB Type-C Partner that supports the alternate mode

const struct typec_altmode_desc * desc Description of the alternate mode

Description

This routine is used to register each alternate mode individually that **partner** has listed in response to Discover SVIDs command. The modes for a SVID listed in response to Discover Modes command need to be listed in an array in **desc**.

Returns handle to the alternate mode on success or NULL on failure.

API for the Cable Plugs:

struct typec_altmode * **typec_plug_register_altmode**(struct typec_plug * plug, const struct typec_altmode_desc * desc)

Register USB Type-C Cable Plug Alternate Mode

Parameters

struct typec_plug * plug USB Type-C Cable Plug that supports the alternate mode

const struct typec_altmode_desc * desc Description of the alternate mode

Description

This routine is used to register each alternate mode individually that **plug** has listed in response to Discover SVIDs command. The modes for a SVID that the

plug lists in response to Discover Modes command need to be listed in an array in **desc**.

Returns handle to the alternate mode on success or ERR_PTR on failure.

So ports, partners and cable plugs will register the alternate modes with their own functions, but the registration will always return a handle to struct typec_altmode on success, or NULL. The unregistration will happen with the same function:

void **typec_unregister_altmode**(struct typec_altmode * adev)
Unregister Alternate Mode

Parameters

struct typec_altmode * adev The alternate mode to be unregistered

Description

Unregister device created with `typec_partner_register_altmode()`, `typec_plug_register_altmode()` or `typec_port_register_altmode()`.

If a partner or cable plug enters or exits a mode, the port driver needs to notify the class with the following API:

void **typec_altmode_update_active**(struct typec_altmode * adev, bool active)
Report Enter/Exit mode

Parameters

struct typec_altmode * adev Handle to the alternate mode

bool active True when the mode has been entered

Description

If a partner or cable plug executes Enter/Exit Mode command successfully, the drivers use this routine to report the updated state of the mode.

Multiplexer/DeMultiplexer Switches

USB Type-C connectors may have one or more mux/demux switches behind them. Since the plugs can be inserted right-side-up or upside-down, a switch is needed to route the correct data pairs from the connector to the USB controllers. If Alternate or Accessory Modes are supported, another switch is needed that can route the pins on the connector to some other component besides USB. USB Type-C Connector Class supplies an API for registering those switches.

struct typec_switch * **typec_switch_register**(struct device * parent, const struct typec_switch_desc * desc)
Register USB Type-C orientation switch

Parameters

struct device * parent Parent device

const struct typec_switch_desc * desc Orientation switch description

Description

This function registers a switch that can be used for routing the correct data pairs depending on the cable plug orientation from the USB Type-C connector to the USB controllers. USB Type-C plugs can be inserted right-side-up or upside-down.

void **typec_switch_unregister**(struct typec_switch * sw)
Unregister USB Type-C orientation switch

Parameters

struct typec_switch * sw USB Type-C orientation switch

Description

Unregister switch that was registered with `typec_switch_register()`.

struct typec_mux * **typec_mux_register**(struct device * parent, const struct typec_mux_desc * desc)
Register Multiplexer routing USB Type-C pins

Parameters

struct device * parent Parent device

const struct typec_mux_desc * desc Multiplexer description

Description

USB Type-C connectors can be used for alternate modes of operation besides USB when Accessory/Alternate Modes are supported. With some of those modes, the pins on the connector need to be reconfigured. This function registers multiplexer switches routing the pins on the connector.

void **typec_mux_unregister**(struct typec_mux * mux)
Unregister Multiplexer Switch

Parameters

struct typec_mux * mux USB Type-C Connector Multiplexer/DeMultiplexer

Description

Unregister mux that was registered with `typec_mux_register()`.

In most cases the same physical mux will handle both the orientation and mode. However, as the port drivers will be responsible for the orientation, and the alternate mode drivers for the mode, the two are always separated into their own logical components: “mux” for the mode and “switch” for the orientation.

When a port is registered, USB Type-C Connector Class requests both the mux and the switch for the port. The drivers can then use the following API for controlling them:

int **typec_set_orientation**(struct typec_port * port, enum typec_orientation orientation)
Set USB Type-C cable plug orientation

Parameters

struct typec_port * port USB Type-C Port

enum typec_orientation orientation USB Type-C cable plug orientation

Description

Set cable plug orientation for **port**.

int **typec_set_mode**(struct typec_port * port, int mode)
Set mode of operation for USB Type-C connector

Parameters

struct typec_port * port USB Type-C connector

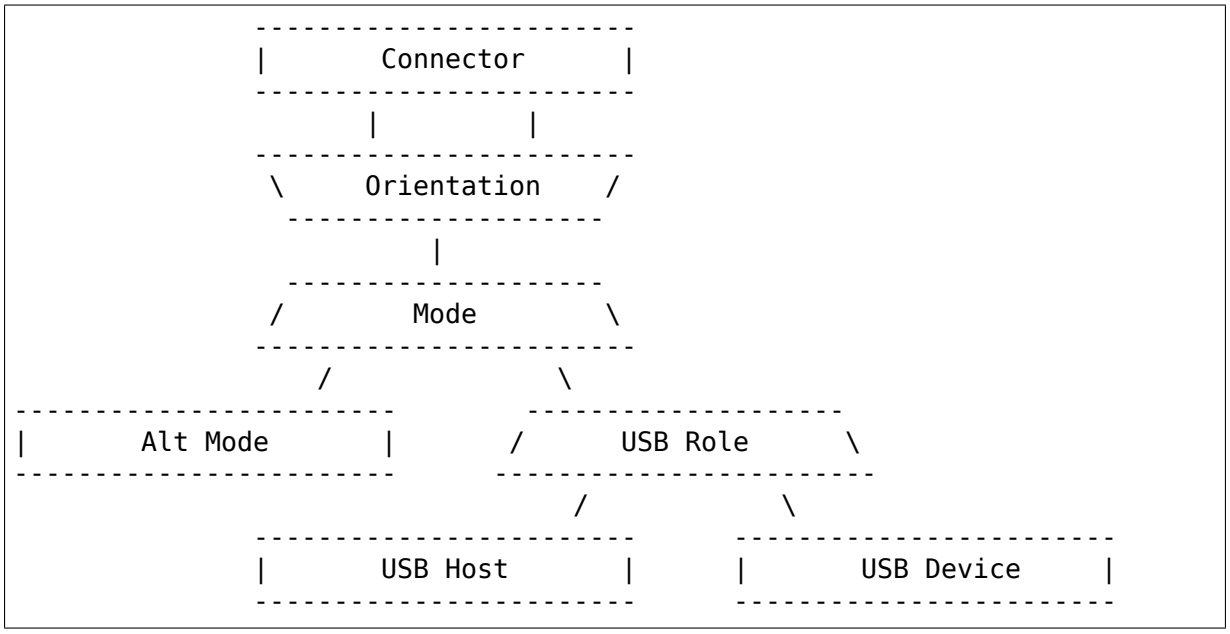
int mode Accessory Mode, USB Operation or Safe State

Description

Configure **port** for Accessory Mode **mode**. This function will configure the muxes needed for **mode**.

If the connector is dual-role capable, there may also be a switch for the data role. USB Type-C Connector Class does not supply separate API for them. The port drivers can use USB Role Class API with those.

Illustration of the muxes behind a connector that supports an alternate mode:



20.16 API for USB Type-C Alternate Mode drivers

20.16.1 Introduction

Alternate modes require communication with the partner using Vendor Defined Messages (VDM) as defined in USB Type-C and USB Power Delivery Specifications. The communication is SVID (Standard or Vendor ID) specific, i.e. specific for every alternate mode, so every alternate mode will need a custom driver.

USB Type-C bus allows binding a driver to the discovered partner alternate modes by using the SVID and the mode number.

USB Type-C Connector Class provides a device for every alternate mode a port supports, and separate device for every alternate mode the partner supports. The drivers for the alternate modes are bound to the partner alternate mode devices, and the port alternate mode devices must be handled by the port drivers.

When a new partner alternate mode device is registered, it is linked to the alternate mode device of the port that the partner is attached to, that has matching SVID and mode. Communication between the port driver and alternate mode driver will happen using the same API.

The port alternate mode devices are used as a proxy between the partner and the alternate mode drivers, so the port drivers are only expected to pass the SVID specific commands from the alternate mode drivers to the partner, and from the partners to the alternate mode drivers. No direct SVID specific communication is needed from the port drivers, but the port drivers need to provide the operation callbacks for the port alternate mode devices, just like the alternate mode drivers need to provide them for the partner alternate mode devices.

20.16.2 Usage:

General

By default, the alternate mode drivers are responsible for entering the mode. It is also possible to leave the decision about entering the mode to the user space (See Documentation/ABI/testing/sysfs-class-typec). Port drivers should not enter any modes on their own.

`->vdm` is the most important callback in the operation callbacks vector. It will be used to deliver all the SVID specific commands from the partner to the alternate mode driver, and vice versa in case of port drivers. The drivers send the SVID specific commands to each other using `typec_altmode_vdm()`.

If the communication with the partner using the SVID specific commands results in need to reconfigure the pins on the connector, the alternate mode driver needs to notify the bus using `typec_altmode_notify()`. The driver passes the negotiated SVID specific pin configuration value to the function as parameter. The bus driver will then configure the mux behind the connector using that value as the state value for the mux.

NOTE: The SVID specific pin configuration values must always start from `TYPEC_STATE_MODAL`. USB Type-C specification defines two default states for the connector: `TYPEC_STATE_USB` and `TYPEC_STATE_SAFE`. These values are reserved by the bus as the first possible values for the state. When the alternate mode is entered, the bus will put the connector into `TYPEC_STATE_SAFE` before sending Enter or Exit Mode command as defined in USB Type-C Specification, and also put the connector back to `TYPEC_STATE_USB` after the mode has been exited.

An example of working definitions for SVID specific pin configurations would look like this:

```
enum {
    ALTMODEX_CONF_A = TYPEC_STATE_MODAL,
    ALTMODEX_CONF_B,
```

(continues on next page)

(continued from previous page)

```
    ...
};
```

Helper macro `TYPEC_MODAL_STATE()` can also be used:

```
#define ALTMODEX_CONF_A = TYPEC_MODAL_STATE(0);
#define ALTMODEX_CONF_B = TYPEC_MODAL_STATE(1);
```

Cable plug alternate modes

The alternate mode drivers are not bound to cable plug alternate mode devices, only to the partner alternate mode devices. If the alternate mode supports, or requires, a cable that responds to SOP Prime, and optionally SOP Double Prime messages, the driver for that alternate mode must request handle to the cable plug alternate modes using `typec_altmode_get_plug()`, and take over their control.

20.16.3 Driver API

Alternate mode driver registering/unregistering

Alternate mode driver operations

int **typec_altmode_notify**(struct typec_altmode * adev, unsigned long conf, void * data)
Communication between the OS and alternate mode driver

Parameters

struct typec_altmode * adev Handle to the alternate mode

unsigned long conf Alternate mode specific configuration value

void * data Alternate mode specific data

Description

The primary purpose for this function is to allow the alternate mode drivers to tell which pin configuration has been negotiated with the partner. That information will then be used for example to configure the muxes. Communication to the other direction is also possible, and low level device drivers can also send notifications to the alternate mode drivers. The actual communication will be specific for every SVID.

int **typec_altmode_enter**(struct typec_altmode * adev, u32 * vdo)
Enter Mode

Parameters

struct typec_altmode * adev The alternate mode

u32 * vdo VDO for the Enter Mode command

Description

The alternate mode drivers use this function to enter mode. The port drivers use this to inform the alternate mode drivers that the partner has initiated Enter Mode command. If the alternate mode does not require VDO, **vdo** must be NULL.

int **typec_altmode_exit**(struct typec_altmode * adev)
Exit Mode

Parameters

struct typec_altmode * adev The alternate mode

Description

The partner of **adev** has initiated Exit Mode command.

void **typec_altmode_attention**(struct typec_altmode * adev, u32 vdo)
Attention command

Parameters

struct typec_altmode * adev The alternate mode

u32 vdo VDO for the Attention command

Description

Notifies the partner of **adev** about Attention command.

int **typec_altmode_vdm**(struct typec_altmode * adev, const u32 header, const u32 * vdo, int count)
Send Vendor Defined Messages (VDM) to the partner

Parameters

struct typec_altmode * adev Alternate mode handle

const u32 header VDM Header

const u32 * vdo Array of Vendor Defined Data Objects

int count Number of Data Objects

Description

The alternate mode drivers use this function for SVID specific communication with the partner. The port drivers use it to deliver the Structured VDMs received from the partners to the alternate mode drivers.

API for the port drivers

struct typec_altmode * **typec_match_altmode**(struct typec_altmode ** altmodes, size_t n, u16 svid, u8 mode)
Match SVID and mode to an array of alternate modes

Parameters

struct typec_altmode ** altmodes Array of alternate modes

size_t n Number of elements in the array, or -1 for NULL terminated arrays

u16 svid Standard or Vendor ID to match with

u8 mode Mode to match with

Description

Return pointer to an alternate mode with SVID matching **svid**, or NULL when no match is found.

Cable Plug operations

struct typec_altmode * **typec_altmode_get_plug**(struct typec_altmode * adev, enum typec_plug_index index)
Find cable plug alternate mode

Parameters

struct typec_altmode * adev Handle to partner alternate mode

enum typec_plug_index index Cable plug index

Description

Increment reference count for cable plug alternate mode device. Returns handle to the cable plug alternate mode, or NULL if none is found.

void **typec_altmode_put_plug**(struct typec_altmode * plug)
Decrement cable plug alternate mode reference count

Parameters

struct typec_altmode * plug Handle to the cable plug alternate mode

20.17 USB3 debug port

Author Lu Baolu <baolu.lu@linux.intel.com>

Date March 2017

20.17.1 GENERAL

This is a HOWTO for using the USB3 debug port on x86 systems.

Before using any kernel debugging functionality based on USB3 debug port, you need to:

```
1) check whether any USB3 debug port is available in
   your system;
2) check which port is used for debugging purposes;
3) have a USB 3.0 super-speed A-to-A debugging cable.
```

20.17.2 INTRODUCTION

The xHCI debug capability (DbC) is an optional but standalone functionality provided by the xHCI host controller. The xHCI specification describes DbC in the section 7.6.

When DbC is initialized and enabled, it will present a debug device through the debug port (normally the first USB3 super-speed port). The debug device is fully compliant with the USB framework and provides the equivalent of a very high performance full-duplex serial link between the debug target (the system under debugging) and a debug host.

20.17.3 EARLY PRINTK

DbC has been designed to log early printk messages. One use for this feature is kernel debugging. For example, when your machine crashes very early before the regular console code is initialized. Other uses include simpler, lockless logging instead of a full- blown printk console driver and klogd.

On the debug target system, you need to customize a debugging kernel with CONFIG_EARLY_PRINTK_USB_XDBC enabled. And, add below kernel boot parameter:

```
"earlyprintk=xdbc"
```

If there are multiple xHCI controllers in your system, you can append a host contoller index to this kernel parameter. This index starts from 0.

Current design doesn’ t support DbC runtime suspend/resume. As the result, you’ d better disable runtime power management for USB subsystem by adding below kernel boot parameter:

```
"usbcore.autosuspend=-1"
```

Before starting the debug target, you should connect the debug port to a USB port (root port or port of any external hub) on the debug host. The cable used to connect these two ports should be a USB 3.0 super-speed A-to-A debugging cable.

During early boot of the debug target, DbC will be detected and initialized. After initialization, the debug host should be able to enumerate the debug device in debug target. The debug host will then bind the debug device with the usb_debug driver module and create the /dev/ttyUSB device.

If the debug device enumeration goes smoothly, you should be able to see below kernel messages on the debug host:

```
# tail -f /var/log/kern.log
[ 1815.983374] usb 4-3: new SuperSpeed USB device number 4 using xhci_hcd
[ 1815.999595] usb 4-3: LPM exit latency is zeroed, disabling LPM.
[ 1815.999899] usb 4-3: New USB device found, idVendor=1d6b, idProduct=0004
[ 1815.999902] usb 4-3: New USB device strings: Mfr=1, Product=2,␣
↪SerialNumber=3
[ 1815.999903] usb 4-3: Product: Remote GDB
[ 1815.999904] usb 4-3: Manufacturer: Linux
[ 1815.999905] usb 4-3: SerialNumber: 0001
```

(continues on next page)

(continued from previous page)

```
[ 1816.000240] usb_debug 4-3:1.0: xhci_dbc converter detected
[ 1816.000360] usb 4-3: xhci_dbc converter now attached to ttyUSB0
```

You can use any communication program, for example minicom, to read and view the messages. Below simple bash scripts can help you to check the sanity of the setup.

```
===== start of bash scripts =============
#!/bin/bash

while true ; do
        while [ ! -d /sys/class/tty/ttyUSB0 ] ; do
                :
        done
cat /dev/ttyUSB0
done
===== end of bash scripts ===============
```

20.17.4 Serial TTY

The DbC support has been added to the xHCI driver. You can get a debug device provided by the DbC at runtime.

In order to use this, you need to make sure your kernel has been configured to support USB_XHCI_DBGCAP. A sysfs attribute under the xHCI device node is used to enable or disable DbC. By default, DbC is disabled:

```
root@target:/sys/bus/pci/devices/0000:00:14.0# cat dbc
disabled
```

Enable DbC with the following command:

```
root@target:/sys/bus/pci/devices/0000:00:14.0# echo enable > dbc
```

You can check the DbC state at anytime:

```
root@target:/sys/bus/pci/devices/0000:00:14.0# cat dbc
enabled
```

Connect the debug target to the debug host with a USB 3.0 super- speed A-to-A debugging cable. You can see /dev/ttyDBC0 created on the debug target. You will see below kernel message lines:

```
root@target: tail -f /var/log/kern.log
[  182.730103] xhci_hcd 0000:00:14.0: DbC connected
[  191.169420] xhci_hcd 0000:00:14.0: DbC configured
[  191.169597] xhci_hcd 0000:00:14.0: DbC now attached to /dev/ttyDBC0
```

Accordingly, the DbC state has been brought up to:

```
root@target:/sys/bus/pci/devices/0000:00:14.0# cat dbc
configured
```

On the debug host, you will see the debug device has been enumerated. You will see below kernel message lines:

```
root@host: tail -f /var/log/kern.log
[   79.454780] usb 2-2.1: new SuperSpeed USB device number 3 using xhci_hcd
[   79.475003] usb 2-2.1: LPM exit latency is zeroed, disabling LPM.
[   79.475389] usb 2-2.1: New USB device found, idVendor=1d6b,␣
↪idProduct=0010
[   79.475390] usb 2-2.1: New USB device strings: Mfr=1, Product=2,␣
↪SerialNumber=3
[   79.475391] usb 2-2.1: Product: Linux USB Debug Target
[   79.475392] usb 2-2.1: Manufacturer: Linux Foundation
[   79.475393] usb 2-2.1: SerialNumber: 0001
```

The debug device works now. You can use any communication or debugging program to talk between the host and the target.

CHAPTER

TWENTYONE

FIREWIRE (IEEE 1394) DRIVER INTERFACE GUIDE

21.1 Introduction and Overview

The Linux FireWire subsystem adds some interfaces into the Linux system to use/maintain+any resource on IEEE 1394 bus.

The main purpose of these interfaces is to access address space on each node on IEEE 1394 bus by ISO/IEC 13213 (IEEE 1212) procedure, and to control isochronous resources on the bus by IEEE 1394 procedure.

Two types of interfaces are added, according to consumers of the interface. A set of userspace interfaces is available via firewire character devices. A set of kernel interfaces is available via exported symbols in firewire-core module.

21.2 Firewire char device data structures

```
What:           /dev/fw[0-9]+
Date:           May 2007
KernelVersion:  2.6.22
Contact:        linux1394-devel@lists.sourceforge.net
Description:
                The character device files /dev/fw* are the␣
↪interface between
                firewire-core and IEEE 1394 device drivers␣
↪implemented in
                userspace.  The ioctl(2)- and read(2)-based ABI is␣
↪defined and
                documented in <linux/firewire-cdev.h>.

                This ABI offers most of the features which␣
↪firewire-core also
                exposes to kernelspace IEEE 1394 drivers.

                Each /dev/fw* is associated with one IEEE 1394 node,
↪ which can
                be remote or local nodes.  Operations on a /dev/fw*␣
↪file have
                different scope:
                  - The 1394 node which is associated with the file:
```

```
                        - Asynchronous request transmission
                        - Get the Configuration ROM
                        - Query node ID
                        - Query maximum speed of the path between␣
↪this node
                          and local node
                  - The 1394 bus (i.e. "card") to which the node is␣
↪attached to:
                        - Isochronous stream transmission and␣
↪reception
                        - Asynchronous stream transmission and␣
↪reception
                        - Asynchronous broadcast request␣
↪transmission
                        - PHY packet transmission and reception
                        - Allocate, reallocate, deallocate␣
↪isochronous
                          resources (channels, bandwidth) at the␣
↪bus's IRM
                        - Query node IDs of local node, root node,
↪ IRM, bus
                          manager
                        - Query cycle time
                        - Bus reset initiation, bus reset event␣
↪reception
                  - All 1394 buses:
                        - Allocation of IEEE 1212 address ranges␣
↪on the local
                          link layers, reception of inbound␣
↪requests to such
                          an address range, asynchronous response␣
↪transmission
                          to inbound requests
                        - Addition of descriptors or directories␣
↪to the local
                          nodes' Configuration ROM

                Due to the different scope of operations and in␣
↪order to let
                userland implement different access permission␣
↪models, some
                operations are restricted to /dev/fw* files that␣
↪are associated
                with a local node:
                        - Addition of descriptors or directories␣
↪to the local
                          nodes' Configuration ROM
                        - PHY packet transmission and reception

                A /dev/fw* file remains associated with one␣
↪particular node
```

```
                during its entire life time.  Bus topology changes,␣
↪and hence
                node ID changes, are tracked by firewire-core.  ABI␣
↪users do not
                need to be aware of topology.

                The following file operations are supported:

                open(2)
                Currently the only useful flags are O_RDWR.

                ioctl(2)
                Initiate various actions.  Some take immediate␣
↪effect, others
                are performed asynchronously while or after the␣
↪ioctl returns.
                See the inline documentation in <linux/
↪firewire-cdev.h> for
                descriptions of all ioctls.

                poll(2), select(2), epoll_wait(2) etc.
                Watch for events to become available to be read.

                read(2)
                Receive various events.  There are solicited events␣
↪like
                outbound asynchronous transaction completion or␣
↪isochronous
                buffer completion, and unsolicited events such as␣
↪bus resets,
                request reception, or PHY packet reception.  Always␣
↪use a read
                buffer which is large enough to receive the largest␣
↪event that
                could ever arrive.  See <linux/firewire-cdev.h> for␣
↪descriptions
                of all event types and for which ioctls affect␣
↪reception of
                events.

                mmap(2)
                Allocate a DMA buffer for isochronous reception or␣
↪transmission
                and map it into the process address space.  The␣
↪arguments should
                be used as follows:  addr = NULL, length = the␣
↪desired buffer
                size, i.e. number of packets times size of largest␣
↪packet,
                prot = at least PROT_READ for reception and at␣
↪least PROT_WRITE
```

```
                for transmission, flags = MAP_SHARED, fd = the␣
↪handle to the
                /dev/fw*, offset = 0.

                Isochronous reception works in packet-per-buffer␣
↪fashion except
                for multichannel reception which works in␣
↪buffer-fill mode.

                munmap(2)
                Unmap the isochronous I/O buffer from the process␣
↪address space.

                close(2)
                Besides stopping and freeing I/O contexts that were␣
↪associated
                with the file descriptor, back out any changes to␣
↪the local
                nodes' Configuration ROM.  Deallocate isochronous␣
↪channels and
                bandwidth at the IRM that were marked for␣
↪kernel-assisted
                re- and deallocation.

```

struct **fw_cdev_event_common**
Common part of all fw_cdev_event_* types

Definition

```
struct fw_cdev_event_common {
  __u64 closure;
  __u32 type;
};
```

Members

closure For arbitrary use by userspace

type Discriminates the fw_cdev_event_* types

Description

This struct may be used to access generic members of all fw_cdev_event_* types regardless of the specific type.

Data passed in the **closure** field for a request will be returned in the corresponding event. It is big enough to hold a pointer on all platforms. The ioctl used to set **closure** depends on the **type** of event.

struct **fw_cdev_event_bus_reset**
Sent when a bus reset occurred

Definition

```
struct fw_cdev_event_bus_reset {
  __u64 closure;
  __u32 type;
  __u32 node_id;
  __u32 local_node_id;
  __u32 bm_node_id;
  __u32 irm_node_id;
  __u32 root_node_id;
  __u32 generation;
};
```

Members

closure See fw_cdev_event_common; set by FW_CDEV_IOC_GET_INFO ioctl

type See fw_cdev_event_common; always FW_CDEV_EVENT_BUS_RESET

node_id New node ID of this node

local_node_id Node ID of the local node, i.e. of the controller

bm_node_id Node ID of the bus manager

irm_node_id Node ID of the iso resource manager

root_node_id Node ID of the root node

generation New bus generation

Description

This event is sent when the bus the device belongs to goes through a bus reset. It provides information about the new bus configuration, such as new node ID for this device, new root ID, and others.

If **bm_node_id** is 0xffff right after bus reset it can be reread by an FW_CDEV_IOC_GET_INFO ioctl after bus manager selection was finished. Kernels with ABI version < 4 do not set **bm_node_id**.

struct **fw_cdev_event_response**
Sent when a response packet was received

Definition

```
struct fw_cdev_event_response {
  __u64 closure;
  __u32 type;
  __u32 rcode;
  __u32 length;
  __u32 data[0];
};
```

Members

closure See fw_cdev_event_common; set by FW_CDEV_IOC_SEND_REQUEST or FW_CDEV_IOC_SEND_BROADCAST_REQUEST or FW_CDEV_IOC_SEND_STREAM_PACKET ioctl

type See fw_cdev_event_common; always FW_CDEV_EVENT_RESPONSE

rcode Response code returned by the remote node

length Data length, i.e. the response's payload size in bytes

data Payload data, if any

Description

This event is sent when the stack receives a response to an outgoing request sent by FW_CDEV_IOC_SEND_REQUEST ioctl. The payload data for responses carrying data (read and lock responses) follows immediately and can be accessed through the **data** field.

The event is also generated after conclusions of transactions that do not involve response packets. This includes unified write transactions, broadcast write transactions, and transmission of asynchronous stream packets. **rcode** indicates success or failure of such transmissions.

struct **fw_cdev_event_request**
Old version of fw_cdev_event_request2

Definition

```
struct fw_cdev_event_request {
  __u64 closure;
  __u32 type;
  __u32 tcode;
  __u64 offset;
  __u32 handle;
  __u32 length;
  __u32 data[0];
};
```

Members

closure See fw_cdev_event_common; set by FW_CDEV_IOC_ALLOCATE ioctl

type See fw_cdev_event_common; always FW_CDEV_EVENT_REQUEST

tcode Transaction code of the incoming request

offset The offset into the 48-bit per-node address space

handle Reference to the kernel-side pending request

length Data length, i.e. the request's payload size in bytes

data Incoming data, if any

Description

This event is sent instead of fw_cdev_event_request2 if the kernel or the client implements ABI version <= 3. fw_cdev_event_request lacks essential information; use fw_cdev_event_request2 instead.

struct **fw_cdev_event_request2**
Sent on incoming request to an address region

Definition

```
struct fw_cdev_event_request2 {
  __u64 closure;
  __u32 type;
  __u32 tcode;
  __u64 offset;
  __u32 source_node_id;
  __u32 destination_node_id;
  __u32 card;

  __u32 handle;
  __u32 length;
  __u32 data[0];
};
```

Members

closure See fw_cdev_event_common; set by FW_CDEV_IOC_ALLOCATE ioctl

type See fw_cdev_event_common; always FW_CDEV_EVENT_REQUEST2

tcode Transaction code of the incoming request

offset The offset into the 48-bit per-node address space

source_node_id Sender node ID

destination_node_id Destination node ID

card The index of the card from which the request came

generation Bus generation in which the request is valid

handle Reference to the kernel-side pending request

length Data length, i.e. the request’ s payload size in bytes

data Incoming data, if any

Description

This event is sent when the stack receives an incoming request to an address region registered using the FW_CDEV_IOC_ALLOCATE ioctl. The request is guaranteed to be completely contained in the specified region. Userspace is responsible for sending the response by FW_CDEV_IOC_SEND_RESPONSE ioctl, using the same **handle**.

The payload data for requests carrying data (write and lock requests) follows immediately and can be accessed through the **data** field.

Unlike fw_cdev_event_request, **tcode** of lock requests is one of the firewire-core specific TCODE_LOCK_MASK_SWAP…``TCODE_LOCK_VENDOR_DEPENDENT``, i.e. encodes the extended transaction code.

card may differ from fw_cdev_get_info.card because requests are received from all cards of the Linux host. **source_node_id**, **destination_node_id**, and **generation** pertain to that card. Destination node ID and bus generation may therefore differ from the corresponding fields of the last fw_cdev_event_bus_reset.

destination_node_id may also differ from the current node ID because of a non-local bus ID part or in case of a broadcast write request. Note, a client must call an FW_CDEV_IOC_SEND_RESPONSE ioctl even in case of a broadcast write request; the kernel will then release the kernel-side pending request but will not actually send a response packet.

In case of a write request to FCP_REQUEST or FCP_RESPONSE, the kernel already sent a write response immediately after the request was received; in this case the client must still call an FW_CDEV_IOC_SEND_RESPONSE ioctl to release the kernel-side pending request, though another response won't be sent.

If the client subsequently needs to initiate requests to the sender node of an fw_cdev_event_request2, it needs to use a device file with matching card index, node ID, and generation for outbound requests.

struct **fw_cdev_event_iso_interrupt**
Sent when an iso packet was completed

Definition

```
struct fw_cdev_event_iso_interrupt {
  __u64 closure;
  __u32 type;
  __u32 cycle;
  __u32 header_length;
  __u32 header[0];
};
```

Members

closure See fw_cdev_event_common; set by FW_CDEV_CREATE_ISO_CONTEXT ioctl

type See fw_cdev_event_common; always FW_CDEV_EVENT_ISO_INTERRUPT

cycle Cycle counter of the last completed packet

header_length Total length of following headers, in bytes

header Stripped headers, if any

Description

This event is sent when the controller has completed an fw_cdev_iso_packet with the FW_CDEV_ISO_INTERRUPT bit set, when explicitly requested with FW_CDEV_IOC_FLUSH_ISO, or when there have been so many completed packets without the interrupt bit set that the kernel's internal buffer for **header** is about to overflow. (In the last case, ABI versions < 5 drop header data up to the next interrupt packet.)

Isochronous transmit events (context type FW_CDEV_ISO_CONTEXT_TRANSMIT):

In version 3 and some implementations of version 2 of the ABI, header_length is a multiple of 4 and header contains timestamps of all packets up until the interrupt packet. The format of the timestamps is as described below for isochronous reception. In version 1 of the ABI, header_length was 0.

Isochronous receive events (context type FW_CDEV_ISO_CONTEXT_RECEIVE):

The headers stripped of all packets up until and including the interrupt packet are returned in the **header** field. The amount of header data per packet is as specified

at iso context creation by `fw_cdev_create_iso_context.header_size`.

Hence, _interrupt.header_length / _context.header_size is the number of packets received in this interrupt event. The client can now iterate through the mmap()'ed DMA buffer according to this number of packets and to the buffer sizes as the client specified in `fw_cdev_queue_iso`.

Since version 2 of this ABI, the portion for each packet in _interrupt.header consists of the 1394 isochronous packet header, followed by a timestamp quadlet if `fw_cdev_create_iso_context.header_size` > 4, followed by quadlets from the packet payload if `fw_cdev_create_iso_context.header_size` > 8.

Format of 1394 iso packet header: 16 bits data_length, 2 bits tag, 6 bits channel, 4 bits tcode, 4 bits sy, in big endian byte order. data_length is the actual received size of the packet without the four 1394 iso packet header bytes.

Format of timestamp: 16 bits invalid, 3 bits cycleSeconds, 13 bits cycleCount, in big endian byte order.

In version 1 of the ABI, no timestamp quadlet was inserted; instead, payload data followed directly after the 1394 is header if header_size > 4. Behaviour of ver. 1 of this ABI is no longer available since ABI ver. 2.

struct **fw_cdev_event_iso_interrupt_mc**
An iso buffer chunk was completed

Definition

```
struct fw_cdev_event_iso_interrupt_mc {
  __u64 closure;
  __u32 type;
  __u32 completed;
};
```

Members

`closure` See `fw_cdev_event_common`; set by `FW_CDEV_CREATE_ISO_CONTEXT` ioctl

`type` `FW_CDEV_EVENT_ISO_INTERRUPT_MULTICHANNEL`

`completed` Offset into the receive buffer; data before this offset is valid

Description

This event is sent in multichannel contexts (context type `FW_CDEV_ISO_CONTEXT_RECEIVE_MULTICHANNEL`) for `fw_cdev_iso_packet` buffer chunks that have been completely filled and that have the `FW_CDEV_ISO_INTERRUPT` bit set, or when explicitly requested with `FW_CDEV_IOC_FLUSH_ISO`.

The buffer is continuously filled with the following data, per packet:

- the 1394 iso packet header as described at `fw_cdev_event_iso_interrupt`, but in little endian byte order,
- packet payload (as many bytes as specified in the data_length field of the 1394 iso packet header) in big endian byte order,
- 0⋯3 padding bytes as needed to align the following trailer quadlet,
- trailer quadlet, containing the reception timestamp as described at `fw_cdev_event_iso_interrupt`, but in little endian byte order.

Hence the per-packet size is data_length (rounded up to a multiple of 4) + 8. When processing the data, stop before a packet that would cross the **completed** offset.

A packet near the end of a buffer chunk will typically spill over into the next queued buffer chunk. It is the responsibility of the client to check for this condition, assemble a broken-up packet from its parts, and not to re-queue any buffer chunks in which as yet unread packet parts reside.

struct **fw_cdev_event_iso_resource**
Iso resources were allocated or freed

Definition

```
struct fw_cdev_event_iso_resource {
  __u64 closure;
  __u32 type;
  __u32 handle;
  __s32 channel;
  __s32 bandwidth;
};
```

Members

closure See fw_cdev_event_common; set by``FW_CDEV_IOC_(DE)ALLOCATE_ISO_RESOURC
ioctl

type FW_CDEV_EVENT_ISO_RESOURCE_ALLOCATED or FW_CDEV_EVENT_ISO_RESOURCE_DEALLOCATE

handle Reference by which an allocated resource can be deallocated

channel Isochronous channel which was (de)allocated, if any

bandwidth Bandwidth allocation units which were (de)allocated, if any

Description

An FW_CDEV_EVENT_ISO_RESOURCE_ALLOCATED event is sent after an isochronous resource was allocated at the IRM. The client has to check **channel** and **bandwidth** for whether the allocation actually succeeded.

An FW_CDEV_EVENT_ISO_RESOURCE_DEALLOCATED event is sent after an isochronous resource was deallocated at the IRM. It is also sent when automatic reallocation after a bus reset failed.

channel is <0 if no channel was (de)allocated or if reallocation failed. **bandwidth** is 0 if no bandwidth was (de)allocated or if reallocation failed.

struct **fw_cdev_event_phy_packet**
A PHY packet was transmitted or received

Definition

```
struct fw_cdev_event_phy_packet {
  __u64 closure;
  __u32 type;
  __u32 rcode;
  __u32 length;
  __u32 data[0];
};
```

Members

closure See fw_cdev_event_common; set by FW_CDEV_IOC_SEND_PHY_PACKET or FW_CDEV_IOC_RECEIVE_PHY_PACKETS ioctl

type FW_CDEV_EVENT_PHY_PACKET_SENT or %⋯_RECEIVED

rcode RCODE_⋯, indicates success or failure of transmission

length Data length in bytes

data Incoming data

Description

If **type** is FW_CDEV_EVENT_PHY_PACKET_SENT, **length** is 0 and **data** empty, except in case of a ping packet: Then, **length** is 4, and **data**[0] is the ping time in 49.152MHz clocks if **rcode** is RCODE_COMPLETE.

If **type** is FW_CDEV_EVENT_PHY_PACKET_RECEIVED, **length** is 8 and **data** consists of the two PHY packet quadlets, in host byte order.

union **fw_cdev_event**
Convenience union of fw_cdev_event_* types

Definition

```
union fw_cdev_event {
  struct fw_cdev_event_common             common;
  struct fw_cdev_event_bus_reset          bus_reset;
  struct fw_cdev_event_response           response;
  struct fw_cdev_event_request            request;
  struct fw_cdev_event_request2           request2;
  struct fw_cdev_event_iso_interrupt      iso_interrupt;
  struct fw_cdev_event_iso_interrupt_mc   iso_interrupt_mc;
  struct fw_cdev_event_iso_resource       iso_resource;
  struct fw_cdev_event_phy_packet         phy_packet;
};
```

Members

common Valid for all types

bus_reset Valid if **common.type** == FW_CDEV_EVENT_BUS_RESET

response Valid if **common.type** == FW_CDEV_EVENT_RESPONSE

request Valid if **common.type** == FW_CDEV_EVENT_REQUEST

request2 Valid if **common.type** == FW_CDEV_EVENT_REQUEST2

iso_interrupt Valid if **common.type** == FW_CDEV_EVENT_ISO_INTERRUPT

iso_interrupt_mc Valid if **common.type** == FW_CDEV_EVENT_ISO_INTERRUPT_MULTICHANNEL

iso_resource Valid if **common.type** == FW_CDEV_EVENT_ISO_RESOURCE_ALLOCATED or FW_CDEV_EVENT_ISO_RESOURCE_DEALLOCATED

phy_packet Valid if **common.type** == FW_CDEV_EVENT_PHY_PACKET_SENT or FW_CDEV_EVENT_PHY_PACKET_RECEIVED

Description

Convenience union for userspace use. Events could be read(2) into an appropriately aligned char buffer and then cast to this union for further processing. Note that for a request, response or iso_interrupt event, the data[] or header[] may make the size of the full event larger than sizeof(union fw_cdev_event). Also note that if you attempt to read(2) an event into a buffer that is not large enough for it, the data that does not fit will be discarded so that the next read(2) will return a new event.

struct **fw_cdev_get_info**
General purpose information ioctl

Definition

```
struct fw_cdev_get_info {
  __u32 version;
  __u32 rom_length;
  __u64 rom;
  __u64 bus_reset;
  __u64 bus_reset_closure;
  __u32 card;
};
```

Members

version The version field is just a running serial number. Both an input parameter (ABI version implemented by the client) and output parameter (ABI version implemented by the kernel). A client shall fill in the ABI **version** for which the client was implemented. This is necessary for forward compatibility.

rom_length If **rom** is non-zero, up to **rom_length** bytes of Configuration ROM will be copied into that user space address. In either case, **rom_length** is updated with the actual length of the Configuration ROM.

rom If non-zero, address of a buffer to be filled by a copy of the device's Configuration ROM

bus_reset If non-zero, address of a buffer to be filled by a `struct fw_cdev_event_bus_reset` with the current state of the bus. This does not cause a bus reset to happen.

bus_reset_closure Value of `closure` in this and subsequent bus reset events

card The index of the card this device belongs to

Description

The `FW_CDEV_IOC_GET_INFO` ioctl is usually the very first one which a client performs right after it opened a /dev/fw* file.

As a side effect, reception of `FW_CDEV_EVENT_BUS_RESET` events to be read(2) is started by this ioctl.

struct **fw_cdev_send_request**
Send an asynchronous request packet

Definition

```
struct fw_cdev_send_request {
  __u32 tcode;
  __u32 length;
  __u64 offset;
  __u64 closure;
  __u64 data;
  __u32 generation;
};
```

Members

tcode Transaction code of the request

length Length of outgoing payload, in bytes

offset 48-bit offset at destination node

closure Passed back to userspace in the response event

data Userspace pointer to payload

generation The bus generation where packet is valid

Description

Send a request to the device. This ioctl implements all outgoing requests. Both quadlet and block request specify the payload as a pointer to the data in the **data** field. Once the transaction completes, the kernel writes an `fw_cdev_event_response` event back. The **closure** field is passed back to user space in the response event.

struct **fw_cdev_send_response**
Send an asynchronous response packet

Definition

```
struct fw_cdev_send_response {
  __u32 rcode;
  __u32 length;
  __u64 data;
  __u32 handle;
};
```

Members

rcode Response code as determined by the userspace handler

length Length of outgoing payload, in bytes

data Userspace pointer to payload

handle The handle from the `fw_cdev_event_request`

Description

Send a response to an incoming request. By setting up an address range using the `FW_CDEV_IOC_ALLOCATE` ioctl, userspace can listen for incoming requests. An incoming request will generate an `FW_CDEV_EVENT_REQUEST`, and userspace must send a reply using this ioctl. The event has a handle to the kernel-side pending transaction, which should be used with this ioctl.

struct **fw_cdev_allocate**
Allocate a CSR in an address range

Definition

```
struct fw_cdev_allocate {
  __u64 offset;
  __u64 closure;
  __u32 length;
  __u32 handle;
  __u64 region_end;
};
```

Members

offset Start offset of the address range

closure To be passed back to userspace in request events

length Length of the CSR, in bytes

handle Handle to the allocation, written by the kernel

region_end First address above the address range (added in ABI v4, 2.6.36)

Description

Allocate an address range in the 48-bit address space on the local node (the controller). This allows userspace to listen for requests with an offset within that address range. Every time when the kernel receives a request within the range, an `fw_cdev_event_request2` event will be emitted. (If the kernel or the client implements ABI version <= 3, an `fw_cdev_event_request` will be generated instead.)

The **closure** field is passed back to userspace in these request events. The **handle** field is an out parameter, returning a handle to the allocated range to be used for later deallocation of the range.

The address range is allocated on all local nodes. The address allocation is exclusive except for the FCP command and response registers. If an exclusive address region is already in use, the ioctl fails with errno set to `EBUSY`.

If kernel and client implement ABI version >= 4, the kernel looks up a free spot of size **length** inside [**offset**..**region_end**) and, if found, writes the start address of the new CSR back in **offset**. I.e. **offset** is an in and out parameter. If this automatic placement of a CSR in a bigger address range is not desired, the client simply needs to set **region_end** = **offset** + **length**.

If the kernel or the client implements ABI version <= 3, **region_end** is ignored and effectively assumed to be **offset** + **length**.

region_end is only present in a kernel header >= 2.6.36. If necessary, this can for example be tested by #ifdef FW_CDEV_EVENT_REQUEST2.

struct **fw_cdev_deallocate**
Free a CSR address range or isochronous resource

Definition

```
struct fw_cdev_deallocate {
  __u32 handle;
};
```

Members

handle Handle to the address range or iso resource, as returned by the kernel when the range or resource was allocated

struct **fw_cdev_initiate_bus_reset**
Initiate a bus reset

Definition

```
struct fw_cdev_initiate_bus_reset {
  __u32 type;
};
```

Members

type FW_CDEV_SHORT_RESET or FW_CDEV_LONG_RESET

Description

Initiate a bus reset for the bus this device is on. The bus reset can be either the original (long) bus reset or the arbitrated (short) bus reset introduced in 1394a-2000.

The ioctl returns immediately. A subsequent fw_cdev_event_bus_reset indicates when the reset actually happened. Since ABI v4, this may be considerably later than the ioctl because the kernel ensures a grace period between subsequent bus resets as per IEEE 1394 bus management specification.

struct **fw_cdev_add_descriptor**
Add contents to the local node's config ROM

Definition

```
struct fw_cdev_add_descriptor {
  __u32 immediate;
  __u32 key;
  __u64 data;
  __u32 length;
  __u32 handle;
};
```

Members

immediate If non-zero, immediate key to insert before pointer

key Upper 8 bits of root directory pointer

data Userspace pointer to contents of descriptor block

length Length of descriptor block data, in quadlets

handle Handle to the descriptor, written by the kernel

Description

Add a descriptor block and optionally a preceding immediate key to the local node's Configuration ROM.

The **key** field specifies the upper 8 bits of the descriptor root directory pointer and the **data** and **length** fields specify the contents. The **key** should be of the form 0xXX000000. The offset part of the root directory entry will be filled in by the kernel.

If not 0, the **immediate** field specifies an immediate key which will be inserted before the root directory pointer.

immediate, **key**, and **data** array elements are CPU-endian quadlets.

If successful, the kernel adds the descriptor and writes back a **handle** to the kernel-side object to be used for later removal of the descriptor block and immediate key. The kernel will also generate a bus reset to signal the change of the Configuration ROM to other nodes.

This ioctl affects the Configuration ROMs of all local nodes. The ioctl only succeeds on device files which represent a local node.

struct **fw_cdev_remove_descriptor**
Remove contents from the Configuration ROM

Definition

```
struct fw_cdev_remove_descriptor {
  __u32 handle;
};
```

Members

handle Handle to the descriptor, as returned by the kernel when the descriptor was added

Description

Remove a descriptor block and accompanying immediate key from the local nodes' Configuration ROMs. The kernel will also generate a bus reset to signal the change of the Configuration ROM to other nodes.

struct **fw_cdev_create_iso_context**
Create a context for isochronous I/O

Definition

```
struct fw_cdev_create_iso_context {
  __u32 type;
  __u32 header_size;
  __u32 channel;
  __u32 speed;
  __u64 closure;
  __u32 handle;
};
```

Members

type FW_CDEV_ISO_CONTEXT_TRANSMIT or FW_CDEV_ISO_CONTEXT_RECEIVE or FW_CDEV_ISO_CONTEXT_RECEIVE_MULTICHANNEL

header_size Header size to strip in single-channel reception

channel Channel to bind to in single-channel reception or transmission

speed Transmission speed

closure To be returned in `fw_cdev_event_iso_interrupt` or `fw_cdev_event_iso_interrupt_multichannel`

handle Handle to context, written back by kernel

Description

Prior to sending or receiving isochronous I/O, a context must be created. The context records information about the transmit or receive configuration and typically maps to an underlying hardware resource. A context is set up for either sending or receiving. It is bound to a specific isochronous **channel**.

In case of multichannel reception, **header_size** and **channel** are ignored and the channels are selected by `FW_CDEV_IOC_SET_ISO_CHANNELS`.

For `FW_CDEV_ISO_CONTEXT_RECEIVE` contexts, **header_size** must be at least 4 and must be a multiple of 4. It is ignored in other context types.

speed is ignored in receive context types.

If a context was successfully created, the kernel writes back a handle to the context, which must be passed in for subsequent operations on that context.

Limitations: No more than one iso context can be created per fd. The total number of contexts that all userspace and kernelspace drivers can create on a card at a time is a hardware limit, typically 4 or 8 contexts per direction, and of them at most one multichannel receive context.

struct **fw_cdev_set_iso_channels**
Select channels in multichannel reception

Definition

```
struct fw_cdev_set_iso_channels {
  __u64 channels;
  __u32 handle;
};
```

Members

channels Bitmask of channels to listen to

handle Handle of the mutichannel receive context

Description

channels is the bitwise or of 1ULL << n for each channel n to listen to.

The ioctl fails with errno `EBUSY` if there is already another receive context on a channel in **channels**. In that case, the bitmask of all unoccupied channels is returned in **channels**.

struct **fw_cdev_iso_packet**
Isochronous packet

Definition

```
struct fw_cdev_iso_packet {
  __u32 control;
  __u32 header[0];
};
```

Members

control Contains the header length (8 uppermost bits), the sy field (4 bits), the tag field (2 bits), a sync flag or a skip flag (1 bit), an interrupt flag (1 bit), and the payload length (16 lowermost bits)

header Header and payload in case of a transmit context.

Description

`struct fw_cdev_iso_packet` is used to describe isochronous packet queues. Use the FW_CDEV_ISO_* macros to fill in **control**. The **header** array is empty in case of receive contexts.

Context type `FW_CDEV_ISO_CONTEXT_TRANSMIT`:

control.HEADER_LENGTH must be a multiple of 4. It specifies the numbers of bytes in **header** that will be prepended to the packet's payload. These bytes are copied into the kernel and will not be accessed after the ioctl has returned.

The **control.SY** and TAG fields are copied to the iso packet header. These fields are specified by IEEE 1394a and IEC 61883-1.

The **control.SKIP** flag specifies that no packet is to be sent in a frame. When using this, all other fields except **control.INTERRUPT** must be zero.

When a packet with the **control.INTERRUPT** flag set has been completed, an `fw_cdev_event_iso_interrupt` event will be sent.

Context type `FW_CDEV_ISO_CONTEXT_RECEIVE`:

control.HEADER_LENGTH must be a multiple of the context's header_size. If the HEADER_LENGTH is larger than the context's header_size, multiple packets are queued for this entry.

The **control.SY** and TAG fields are ignored.

If the **control.SYNC** flag is set, the context drops all packets until a packet with a sy field is received which matches `fw_cdev_start_iso.sync`.

control.PAYLOAD_LENGTH defines how many payload bytes can be received for one packet (in addition to payload quadlets that have been defined as headers and are stripped and returned in the `fw_cdev_event_iso_interrupt` structure). If more bytes are received, the additional bytes are dropped. If less bytes are received, the remaining bytes in this part of the payload buffer will not be written to, not even by the next packet. I.e., packets received in consecutive frames will not necessarily be consecutive in memory. If an entry has queued multiple packets, the PAYLOAD_LENGTH is divided equally among them.

When a packet with the **control.INTERRUPT** flag set has been completed, an `fw_cdev_event_iso_interrupt` event will be sent. An entry that has queued multiple receive packets is completed when its last packet is completed.

Context type `FW_CDEV_ISO_CONTEXT_RECEIVE_MULTICHANNEL`:

Here, `fw_cdev_iso_packet` would be more aptly named _iso_buffer_chunk since it specifies a chunk of the mmap()'ed buffer, while the number and alignment of packets to be placed into the buffer chunk is not known beforehand.

control.PAYLOAD_LENGTH is the size of the buffer chunk and specifies room for header, payload, padding, and trailer bytes of one or more packets. It must be a multiple of 4.

control.HEADER_LENGTH, TAG and SY are ignored. SYNC is treated as described for single-channel reception.

When a buffer chunk with the **control.INTERRUPT** flag set has been filled entirely, an `fw_cdev_event_iso_interrupt_mc` event will be sent.

struct **fw_cdev_queue_iso**
Queue isochronous packets for I/O

Definition

```
struct fw_cdev_queue_iso {
  __u64 packets;
  __u64 data;
  __u32 size;
  __u32 handle;
};
```

Members

packets Userspace pointer to an array of `fw_cdev_iso_packet`

data Pointer into mmap()'ed payload buffer

size Size of the **packets** array, in bytes

handle Isochronous context handle

Description

Queue a number of isochronous packets for reception or transmission. This ioctl takes a pointer to an array of `fw_cdev_iso_packet` structs, which describe how to transmit from or receive into a contiguous region of a mmap()'ed payload buffer. As part of transmit packet descriptors, a series of headers can be supplied, which will be prepended to the payload during DMA.

The kernel may or may not queue all packets, but will write back updated values of the **packets**, **data** and **size** fields, so the ioctl can be resubmitted easily.

In case of a multichannel receive context, **data** must be quadlet-aligned relative to the buffer start.

struct **fw_cdev_start_iso**
Start an isochronous transmission or reception

Definition

```
struct fw_cdev_start_iso {
  __s32 cycle;
  __u32 sync;
  __u32 tags;
```

(continues on next page)

(continued from previous page)

```
  __u32 handle;
};
```

Members

cycle Cycle in which to start I/O. If **cycle** is greater than or equal to 0, the I/O will start on that cycle.

sync Determines the value to wait for for receive packets that have the FW_CDEV_ISO_SYNC bit set

tags Tag filter bit mask. Only valid for isochronous reception. Determines the tag values for which packets will be accepted. Use FW_CDEV_ISO_CONTEXT_MATCH_* macros to set **tags**.

handle Isochronous context handle within which to transmit or receive

struct **fw_cdev_stop_iso**
Stop an isochronous transmission or reception

Definition

```
struct fw_cdev_stop_iso {
  __u32 handle;
};
```

Members

handle Handle of isochronous context to stop

struct **fw_cdev_flush_iso**
flush completed iso packets

Definition

```
struct fw_cdev_flush_iso {
  __u32 handle;
};
```

Members

handle handle of isochronous context to flush

Description

For FW_CDEV_ISO_CONTEXT_TRANSMIT or FW_CDEV_ISO_CONTEXT_RECEIVE contexts, report any completed packets.

For FW_CDEV_ISO_CONTEXT_RECEIVE_MULTICHANNEL contexts, report the current offset in the receive buffer, if it has changed; this is typically in the middle of some buffer chunk.

Any FW_CDEV_EVENT_ISO_INTERRUPT or FW_CDEV_EVENT_ISO_INTERRUPT_MULTICHANNEL events generated by this ioctl are sent synchronously, i.e., are available for reading from the file descriptor when this ioctl returns.

struct **fw_cdev_get_cycle_timer**
read cycle timer register

Definition

```
struct fw_cdev_get_cycle_timer {
  __u64 local_time;
  __u32 cycle_timer;
};
```

Members

local_time system time, in microseconds since the Epoch

cycle_timer Cycle Time register contents

Description

Same as FW_CDEV_IOC_GET_CYCLE_TIMER2, but fixed to use CLOCK_REALTIME and only with microseconds resolution.

In version 1 and 2 of the ABI, this ioctl returned unreliable (non- monotonic) **cycle_timer** values on certain controllers.

struct **fw_cdev_get_cycle_timer2**
read cycle timer register

Definition

```
struct fw_cdev_get_cycle_timer2 {
  __s64 tv_sec;
  __s32 tv_nsec;
  __s32 clk_id;
  __u32 cycle_timer;
};
```

Members

tv_sec system time, seconds

tv_nsec system time, sub-seconds part in nanoseconds

clk_id input parameter, clock from which to get the system time

cycle_timer Cycle Time register contents

Description

The FW_CDEV_IOC_GET_CYCLE_TIMER2 ioctl reads the isochronous cycle timer and also the system clock. This allows to correlate reception time of isochronous packets with system time.

clk_id lets you choose a clock like with POSIX' clock_gettime function. Supported **clk_id** values are POSIX' CLOCK_REALTIME and CLOCK_MONOTONIC and Linux' CLOCK_MONOTONIC_RAW.

cycle_timer consists of 7 bits cycleSeconds, 13 bits cycleCount, and 12 bits cycleOffset, in host byte order. Cf. the Cycle Time register per IEEE 1394 or Isochronous Cycle Timer register per OHCI-1394.

struct **fw_cdev_allocate_iso_resource**
(De)allocate a channel or bandwidth

Definition

```
struct fw_cdev_allocate_iso_resource {
  __u64 closure;
  __u64 channels;
  __u32 bandwidth;
  __u32 handle;
};
```

Members

closure Passed back to userspace in corresponding iso resource events

channels Isochronous channels of which one is to be (de)allocated

bandwidth Isochronous bandwidth units to be (de)allocated

handle Handle to the allocation, written by the kernel (only valid in case of `FW_CDEV_IOC_ALLOCATE_ISO_RESOURCE` ioctls)

Description

The `FW_CDEV_IOC_ALLOCATE_ISO_RESOURCE` ioctl initiates allocation of an isochronous channel and/or of isochronous bandwidth at the isochronous resource manager (IRM). Only one of the channels specified in **channels** is allocated. An `FW_CDEV_EVENT_ISO_RESOURCE_ALLOCATED` is sent after communication with the IRM, indicating success or failure in the event data. The kernel will automatically reallocate the resources after bus resets. Should a reallocation fail, an `FW_CDEV_EVENT_ISO_RESOURCE_DEALLOCATED` event will be sent. The kernel will also automatically deallocate the resources when the file descriptor is closed.

The `FW_CDEV_IOC_DEALLOCATE_ISO_RESOURCE` ioctl can be used to initiate deallocation of resources which were allocated as described above. An `FW_CDEV_EVENT_ISO_RESOURCE_DEALLOCATED` event concludes this operation.

The `FW_CDEV_IOC_ALLOCATE_ISO_RESOURCE_ONCE` ioctl is a variant of allocation without automatic re- or deallocation. An `FW_CDEV_EVENT_ISO_RESOURCE_ALLOCATED` event concludes this operation, indicating success or failure in its data.

The `FW_CDEV_IOC_DEALLOCATE_ISO_RESOURCE_ONCE` ioctl works like `FW_CDEV_IOC_ALLOCATE_ISO_RESOURCE_ONCE` except that resources are freed instead of allocated. An `FW_CDEV_EVENT_ISO_RESOURCE_DEALLOCATED` event concludes this operation.

To summarize, `FW_CDEV_IOC_ALLOCATE_ISO_RESOURCE` allocates iso resources for the lifetime of the fd or **handle**. In contrast, `FW_CDEV_IOC_ALLOCATE_ISO_RESOURCE_ONCE` allocates iso resources for the duration of a bus generation.

channels is a host-endian bitfield with the least significant bit representing channel 0 and the most significant bit representing channel 63: 1ULL << c for each channel c that is a candidate for (de)allocation.

bandwidth is expressed in bandwidth allocation units, i.e. the time to send one quadlet of data (payload or header data) at speed S1600.

struct **fw_cdev_send_stream_packet**
send an asynchronous stream packet

Definition

```
struct fw_cdev_send_stream_packet {
  __u32 length;
  __u32 tag;
  __u32 channel;
  __u32 sy;
  __u64 closure;
  __u64 data;
  __u32 generation;
  __u32 speed;
};
```

Members

length Length of outgoing payload, in bytes

tag Data format tag

channel Isochronous channel to transmit to

sy Synchronization code

closure Passed back to userspace in the response event

data Userspace pointer to payload

generation The bus generation where packet is valid

speed Speed to transmit at

Description

The FW_CDEV_IOC_SEND_STREAM_PACKET ioctl sends an asynchronous stream packet to every device which is listening to the specified channel. The kernel writes an fw_cdev_event_response event which indicates success or failure of the transmission.

struct **fw_cdev_send_phy_packet**
send a PHY packet

Definition

```
struct fw_cdev_send_phy_packet {
  __u64 closure;
  __u32 data[2];
  __u32 generation;
};
```

Members

closure Passed back to userspace in the PHY-packet-sent event

data First and second quadlet of the PHY packet

generation The bus generation where packet is valid

Description

The FW_CDEV_IOC_SEND_PHY_PACKET ioctl sends a PHY packet to all nodes on the same card as this device. After transmission, an FW_CDEV_EVENT_PHY_PACKET_SENT event is generated.

The payload **data**[] shall be specified in host byte order. Usually, **data**[1] needs to be the bitwise inverse of **data**[0]. VersaPHY packets are an exception to this rule.

The ioctl is only permitted on device files which represent a local node.

struct **fw_cdev_receive_phy_packets**
start reception of PHY packets

Definition

```
struct fw_cdev_receive_phy_packets {
  __u64 closure;
};
```

Members

closure Passed back to userspace in phy packet events

Description

This ioctl activates issuing of FW_CDEV_EVENT_PHY_PACKET_RECEIVED due to incoming PHY packets from any node on the same bus as the device.

The ioctl is only permitted on device files which represent a local node.

21.3 Firewire device probing and sysfs interfaces

Users:          udev rules to create /dev/disk/by-id/ symlinks
```

int **fw_csr_string**(const u32 * directory, int key, char * buf, size_t size)
reads a string from the configuration ROM

Parameters

const u32 * directory e.g. root directory or unit directory

int key the key of the preceding directory entry

char * buf where to put the string

size_t size size of **buf**, in bytes

Description

The string is taken from a minimal ASCII text descriptor leaf after the immediate entry with **key**. The string is zero-terminated. An overlong string is silently truncated such that it and the zero byte fit into **size**.

Returns strlen(buf) or a negative error code.

21.4 Firewire core transaction interfaces

void **fw_send_request**(struct fw_card * card, struct fw_transaction * t, int tcode, int destination_id, int generation, int speed, unsigned long long offset, void * payload, size_t length, fw_transaction_callback_t callback, void * callback_data)

submit a request packet for transmission

Parameters

struct fw_card * card interface to send the request at

struct fw_transaction * t transaction instance to which the request belongs

int tcode transaction code

int destination_id destination node ID, consisting of bus_ID and phy_ID

int generation bus generation in which request and response are valid

int speed transmission speed

unsigned long long offset 48bit wide offset into destination's address space

void * payload data payload for the request subaction

size_t length length of the payload, in bytes

fw_transaction_callback_t callback function to be called when the transaction is completed

void * callback_data data to be passed to the transaction completion callback

Description

Submit a request packet into the asynchronous request transmission queue. Can be called from atomic context. If you prefer a blocking API, use `fw_run_transaction()` in a context that can sleep.

In case of lock requests, specify one of the firewire-core specific `TCODE_` constants instead of `TCODE_LOCK_REQUEST` in **tcode**.

Make sure that the value in **destination_id** is not older than the one in **generation**. Otherwise the request is in danger to be sent to a wrong node.

In case of asynchronous stream packets i.e. `TCODE_STREAM_DATA`, the caller needs to synthesize **destination_id** with fw_stream_packet_destination_id(). It will contain tag, channel, and sy data instead of a node ID then.

The payload buffer at **data** is going to be DMA-mapped except in case of **length** <= 8 or of local (loopback) requests. Hence make sure that the buffer complies with the restrictions of the streaming DMA mapping API. **payload** must not be freed before the **callback** is called.

In case of request types without payload, **data** is NULL and **length** is 0.

After the transaction is completed successfully or unsuccessfully, the **callback** will be called. Among its parameters is the response code which is either one of the rcodes per IEEE 1394 or, in case of internal errors, the firewire-core specific `RCODE_SEND_ERROR`. The other firewire-core specific rcodes (`RCODE_CANCELLED`, `RCODE_BUSY`, `RCODE_GENERATION`, `RCODE_NO_ACK`) denote transaction timeout, busy responder, stale request generation, or missing ACK respectively.

Note some timing corner cases: `fw_send_request()` may complete much earlier than when the request packet actually hits the wire. On the other hand, transaction completion and hence execution of **callback** may happen even before `fw_send_request()` returns.

int **fw_run_transaction**(struct fw_card * card, int tcode, int destination_id, int generation, int speed, unsigned long long offset, void * payload, size_t length)

send request and sleep until transaction is completed

Parameters

struct fw_card * card card interface for this request

int tcode transaction code

int destination_id destination node ID, consisting of bus_ID and phy_ID

int generation bus generation in which request and response are valid

int speed transmission speed

unsigned long long offset 48bit wide offset into destination's address space

void * payload data payload for the request subaction

size_t length length of the payload, in bytes

Description

Returns the RCODE. See `fw_send_request()` for parameter documentation. Unlike `fw_send_request()`, **data** points to the payload of the request or/and to the payload of the response. DMA mapping restrictions apply to outbound request payloads of >= 8 bytes but not to inbound response payloads.

int **fw_core_add_address_handler**(struct fw_address_handler * handler, const struct fw_address_region * region)

register for incoming requests

Parameters

struct fw_address_handler * handler callback

const struct fw_address_region * region region in the IEEE 1212 node space address range

Description

region->start, ->end, and handler->length have to be quadlet-aligned.

When a request is received that falls within the specified address range, the specified callback is invoked. The parameters passed to the callback give the details of the particular request.

To be called in process context. Return value: 0 on success, non-zero otherwise.

The start offset of the handler's address region is determined by `fw_core_add_address_handler()` and is returned in handler->offset.

Address allocations are exclusive, except for the FCP registers.

void **fw_core_remove_address_handler**(struct fw_address_handler * handler)
unregister an address handler

Parameters

struct fw_address_handler * handler callback

Description

To be called in process context.

When `fw_core_remove_address_handler()` returns, **handler->callback()** is guaranteed to not run on any CPU anymore.

int **fw_get_request_speed**(struct fw_request * request)
returns speed at which the **request** was received

Parameters

struct fw_request * request firewire request data

const char * **fw_rcode_string**(int rcode)
convert a firewire result code to an error description

Parameters

int rcode the result code

21.5 Firewire Isochronous I/O interfaces

void **fw_iso_resource_manage**(struct fw_card * card, int generation, u64 channels_mask, int * channel, int * bandwidth, bool allocate)
Allocate or deallocate a channel and/or bandwidth

Parameters

struct fw_card * card card interface for this action

int generation bus generation

u64 channels_mask bitmask for channel allocation

int * channel pointer for returning channel allocation result

int * bandwidth pointer for returning bandwidth allocation result

bool allocate whether to allocate (true) or deallocate (false)

Description

In parameters: card, generation, channels_mask, bandwidth, allocate Out parameters: channel, bandwidth

This function blocks (sleeps) during communication with the IRM.

Allocates or deallocates at most one channel out of channels_mask. channels_mask is a bitfield with MSB for channel 63 and LSB for channel 0. (Note, the IRM's CHANNELS_AVAILABLE is a big-endian bitfield with MSB for channel 0 and LSB for channel 63.) Allocates or deallocates as many bandwidth allocation units as specified.

Returns channel < 0 if no channel was allocated or deallocated. Returns bandwidth = 0 if no bandwidth was allocated or deallocated.

If generation is stale, deallocations succeed but allocations fail with channel = -EAGAIN.

If channel allocation fails, no bandwidth will be allocated either. If bandwidth allocation fails, no channel will be allocated either. But deallocations of channel and bandwidth are tried independently of each other's success.

THE LINUX PCI DRIVER IMPLEMENTER'S API GUIDE

Table of contents

22.1 PCI Support Library

unsigned char **pci_bus_max_busnr**(struct pci_bus * bus)
returns maximum PCI bus number of given bus' children

Parameters

struct pci_bus * bus pointer to PCI bus structure to search

Description

Given a PCI bus, returns the highest PCI bus number present in the set including the given PCI bus and its list of child PCI buses.

int **pci_status_get_and_clear_errors**(struct pci_dev * pdev)
return and clear error bits in PCI_STATUS

Parameters

struct pci_dev * pdev the PCI device

Description

Returns error bits set in PCI_STATUS and clears them.

int **pci_find_capability**(struct pci_dev * dev, int cap)
query for devices' capabilities

Parameters

struct pci_dev * dev PCI device to query

int cap capability code

Description

Tell if a device supports a given PCI capability. Returns the address of the requested capability structure within the device's PCI configuration space or 0 in case the device does not support it. Possible values for **cap** include:

`PCI_CAP_ID_PM` Power Management `PCI_CAP_ID_AGP` Accelerated Graphics Port `PCI_CAP_ID_VPD` Vital Product Data `PCI_CAP_ID_SLOTID` Slot Identification `PCI_CAP_ID_MSI` Message Signalled Interrupts

PCI_CAP_ID_CHSWP CompactPCI HotSwap PCI_CAP_ID_PCIX PCI-X PCI_CAP_ID_EXP PCI Express

int **pci_bus_find_capability**(struct pci_bus * bus, unsigned int devfn, int cap)
query for devices' capabilities

Parameters

struct pci_bus * bus the PCI bus to query

unsigned int devfn PCI device to query

int cap capability code

Description

Like pci_find_capability() but works for PCI devices that do not have a pci_dev structure set up yet.

Returns the address of the requested capability structure within the device's PCI configuration space or 0 in case the device does not support it.

int **pci_find_next_ext_capability**(struct pci_dev * dev, int start, int cap)
Find an extended capability

Parameters

struct pci_dev * dev PCI device to query

int start address at which to start looking (0 to start at beginning of list)

int cap capability code

Description

Returns the address of the next matching extended capability structure within the device's PCI configuration space or 0 if the device does not support it. Some capabilities can occur several times, e.g., the vendor-specific capability, and this provides a way to find them all.

int **pci_find_ext_capability**(struct pci_dev * dev, int cap)
Find an extended capability

Parameters

struct pci_dev * dev PCI device to query

int cap capability code

Description

Returns the address of the requested extended capability structure within the device's PCI configuration space or 0 if the device does not support it. Possible values for **cap** include:

PCI_EXT_CAP_ID_ERR Advanced Error Reporting PCI_EXT_CAP_ID_VC Virtual Channel PCI_EXT_CAP_ID_DSN Device Serial Number PCI_EXT_CAP_ID_PWR Power Budgeting

u64 **pci_get_dsn**(struct pci_dev * dev)
Read and return the 8-byte Device Serial Number

Parameters

struct pci_dev * dev PCI device to query

Description

Looks up the PCI_EXT_CAP_ID_DSN and reads the 8 bytes of the Device Serial Number.

Returns the DSN, or zero if the capability does not exist.

int **pci_find_next_ht_capability**(struct pci_dev * dev, int pos, int ht_cap)
query a device's Hypertransport capabilities

Parameters

struct pci_dev * dev PCI device to query

int pos Position from which to continue searching

int ht_cap Hypertransport capability code

Description

To be used in conjunction with `pci_find_ht_capability()` to search for all capabilities matching **ht_cap**. **pos** should always be a value returned from `pci_find_ht_capability()`.

NB. To be 100% safe against broken PCI devices, the caller should take steps to avoid an infinite loop.

int **pci_find_ht_capability**(struct pci_dev * dev, int ht_cap)
query a device's Hypertransport capabilities

Parameters

struct pci_dev * dev PCI device to query

int ht_cap Hypertransport capability code

Description

Tell if a device supports a given Hypertransport capability. Returns an address within the device's PCI configuration space or 0 in case the device does not support the request capability. The address points to the PCI capability, of type PCI_CAP_ID_HT, which has a Hypertransport capability matching **ht_cap**.

struct resource * **pci_find_parent_resource**(const struct pci_dev * dev,
struct resource * res)
return resource region of parent bus of given region

Parameters

const struct pci_dev * dev PCI device structure contains resources to be searched

struct resource * res child resource record for which parent is sought

Description

For given resource region of given device, return the resource region of parent bus the given region is contained in.

struct resource * **pci_find_resource**(struct pci_dev * dev, struct resource * res)
Return matching PCI device resource

Parameters

struct pci_dev * dev PCI device to query

struct resource * res Resource to look for

Description

Goes over standard PCI resources (BARs) and checks if the given resource is partially or fully contained in any of them. In that case the matching resource is returned, NULL otherwise.

int **pci_platform_power_transition**(struct pci_dev * dev, pci_power_t state)
Use platform to change device power state

Parameters

struct pci_dev * dev PCI device to handle.

pci_power_t state State to put the device into.

int **pci_set_power_state**(struct pci_dev * dev, pci_power_t state)
Set the power state of a PCI device

Parameters

struct pci_dev * dev PCI device to handle.

pci_power_t state PCI power state (D0, D1, D2, D3hot) to put the device into.

Description

Transition a device to a new power state, using the platform firmware and/or the device's PCI PM registers.

RETURN VALUE: -EINVAL if the requested state is invalid. -EIO if device does not support PCI PM or its PM capabilities register has a wrong version, or device doesn't support the requested state. 0 if the transition is to D1 or D2 but D1 and D2 are not supported. 0 if device already is in the requested state. 0 if the transition is to D3 but D3 is not supported. 0 if device's power state has been successfully changed.

pci_power_t **pci_choose_state**(struct pci_dev * dev, pm_message_t state)
Choose the power state of a PCI device

Parameters

struct pci_dev * dev PCI device to be suspended

pm_message_t state target sleep state for the whole system. This is the value that is passed to suspend() function.

Description

Returns PCI power state suitable for given device and given system message.

int **pci_save_state**(struct pci_dev * dev)
save the PCI configuration space of a device before suspending

Parameters

struct pci_dev * dev PCI device that we're dealing with

void **pci_restore_state**(struct pci_dev * dev)
Restore the saved state of a PCI device

Parameters

struct pci_dev * dev PCI device that we're dealing with

struct pci_saved_state * **pci_store_saved_state**(struct pci_dev * dev)
Allocate and return an opaque struct containing the device saved state.

Parameters

struct pci_dev * dev PCI device that we're dealing with

Description

Return NULL if no state or error.

int **pci_load_saved_state**(struct pci_dev * dev, struct pci_saved_state * state)
Reload the provided save state into struct pci_dev.

Parameters

struct pci_dev * dev PCI device that we're dealing with

struct pci_saved_state * state Saved state returned from `pci_store_saved_state()`

int **pci_load_and_free_saved_state**(struct pci_dev * dev, struct pci_saved_state ** state)
Reload the save state pointed to by state, and free the memory allocated for it.

Parameters

struct pci_dev * dev PCI device that we're dealing with

struct pci_saved_state ** state Pointer to saved state returned from `pci_store_saved_state()`

int **pci_reenable_device**(struct pci_dev * dev)
Resume abandoned device

Parameters

struct pci_dev * dev PCI device to be resumed

NOTE

This function is a backend of pci_default_resume() and is not supposed to be called by normal code, write proper resume handler and use it instead.

int **pci_enable_device_io**(struct pci_dev * dev)
Initialize a device for use with IO space

Parameters

struct pci_dev * dev PCI device to be initialized

Description

Initialize device before it's used by a driver. Ask low-level code to enable I/O resources. Wake up the device if it was suspended. Beware, this function can fail.

int **pci_enable_device_mem**(struct pci_dev * dev)
Initialize a device for use with Memory space

Parameters

struct pci_dev * dev PCI device to be initialized

Description

Initialize device before it's used by a driver. Ask low-level code to enable Memory resources. Wake up the device if it was suspended. Beware, this function can fail.

int **pci_enable_device**(struct pci_dev * dev)
Initialize device before it's used by a driver.

Parameters

struct pci_dev * dev PCI device to be initialized

Description

Initialize device before it's used by a driver. Ask low-level code to enable I/O and memory. Wake up the device if it was suspended. Beware, this function can fail.

Note we don't actually enable the device many times if we call this function repeatedly (we just increment the count).

int **pcim_enable_device**(struct pci_dev * pdev)
Managed `pci_enable_device()`

Parameters

struct pci_dev * pdev PCI device to be initialized

Description

Managed `pci_enable_device()`.

void **pcim_pin_device**(struct pci_dev * pdev)
Pin managed PCI device

Parameters

struct pci_dev * pdev PCI device to pin

Description

Pin managed PCI device **pdev**. Pinned device won't be disabled on driver detach. **pdev** must have been enabled with `pcim_enable_device()`.

void **pci_disable_device**(struct pci_dev * dev)
Disable PCI device after use

Parameters

struct pci_dev * dev PCI device to be disabled

Description

Signal to the system that the PCI device is not in use by the system anymore. This only involves disabling PCI bus-mastering, if active.

Note we don't actually disable the device until all callers of `pci_enable_device()` have called `pci_disable_device()`.

int **pci_set_pcie_reset_state**(struct pci_dev * dev, enum pcie_reset_state state)
set reset state for device dev

Parameters

struct pci_dev * dev the PCIe device reset

enum pcie_reset_state state Reset state to enter into

Description

Sets the PCI reset state for the device.

bool **pci_pme_capable**(struct pci_dev * dev, pci_power_t state)
check the capability of PCI device to generate PME#

Parameters

struct pci_dev * dev PCI device to handle.

pci_power_t state PCI state from which device will issue PME#.

void **pci_pme_active**(struct pci_dev * dev, bool enable)
enable or disable PCI device's PME# function

Parameters

struct pci_dev * dev PCI device to handle.

bool enable 'true' to enable PME# generation; 'false' to disable it.

Description

The caller must verify that the device is capable of generating PME# before calling this function with **enable** equal to 'true'.

int **pci_enable_wake**(struct pci_dev * pci_dev, pci_power_t state, bool enable)
change wakeup settings for a PCI device

Parameters

struct pci_dev * pci_dev Target device

pci_power_t state PCI state from which device will issue wakeup events

bool enable Whether or not to enable event generation

Description

If **enable** is set, check device_may_wakeup() for the device before calling __pci_enable_wake() for it.

int **pci_wake_from_d3**(struct pci_dev * dev, bool enable)
enable/disable device to wake up from D3_hot or D3_cold

Parameters

struct pci_dev * dev PCI device to prepare

bool enable True to enable wake-up event generation; false to disable

Description

Many drivers want the device to wake up the system from D3_hot or D3_cold and this function allows them to set that up cleanly - `pci_enable_wake()` should not be called twice in a row to enable wake-up due to PCI PM vs ACPI ordering constraints.

This function only returns error code if the device is not allowed to wake up the system from sleep or it is not capable of generating PME# from both D3_hot and D3_cold and the platform is unable to enable wake-up power for it.

int **pci_prepare_to_sleep**(struct pci_dev * dev)
prepare PCI device for system-wide transition into a sleep state

Parameters

struct pci_dev * dev Device to handle.

Description

Choose the power state appropriate for the device depending on whether it can wake up the system and/or is power manageable by the platform (PCI_D3hot is the default) and put the device into that state.

int **pci_back_from_sleep**(struct pci_dev * dev)
turn PCI device on during system-wide transition into working state

Parameters

struct pci_dev * dev Device to handle.

Description

Disable device's system wake-up capability and put it into D0.

bool **pci_dev_run_wake**(struct pci_dev * dev)
Check if device can generate run-time wake-up events.

Parameters

struct pci_dev * dev Device to check.

Description

Return true if the device itself is capable of generating wake-up events (through the platform or using the native PCIe PME) or if the device supports PME and one of its upstream bridges can generate wake-up events.

void **pci_d3cold_enable**(struct pci_dev * dev)
Enable D3cold for device

Parameters

struct pci_dev * dev PCI device to handle

Description

This function can be used in drivers to enable D3cold from the device they handle. It also updates upstream PCI bridge PM capabilities accordingly.

void **pci_d3cold_disable**(struct pci_dev * dev)
Disable D3cold for device

Parameters

struct pci_dev * dev PCI device to handle

Description

This function can be used in drivers to disable D3cold from the device they handle. It also updates upstream PCI bridge PM capabilities accordingly.

int **pci_enable_atomic_ops_to_root**(struct pci_dev * dev, u32 cap_mask)
enable AtomicOp requests to root port

Parameters

struct pci_dev * dev the PCI device

u32 cap_mask mask of desired AtomicOp sizes, including one or more of: PCI_EXP_DEVCAP2_ATOMIC_COMP32 PCI_EXP_DEVCAP2_ATOMIC_COMP64 PCI_EXP_DEVCAP2_ATOMIC_COMP128

Description

Return 0 if all upstream bridges support AtomicOp routing, egress blocking is disabled on all upstream ports, and the root port supports the requested completion capabilities (32-bit, 64-bit and/or 128-bit AtomicOp completion), or negative otherwise.

u8 **pci_common_swizzle**(struct pci_dev * dev, u8 * pinp)
swizzle INTx all the way to root bridge

Parameters

struct pci_dev * dev the PCI device

u8 * pinp pointer to the INTx pin value (1=INTA, 2=INTB, 3=INTD, 4=INTD)

Description

Perform INTx swizzling for a device. This traverses through all PCI-to-PCI bridges all the way up to a PCI root bus.

void **pci_release_region**(struct pci_dev * pdev, int bar)
Release a PCI bar

Parameters

struct pci_dev * pdev PCI device whose resources were previously reserved by `pci_request_region()`

int bar BAR to release

Description

Releases the PCI I/O and memory resources previously reserved by a successful call to `pci_request_region()`. Call this function only after all use of the PCI regions has ceased.

int **pci_request_region**(struct pci_dev * pdev, int bar, const char * res_name)
Reserve PCI I/O and memory resource

Parameters

struct pci_dev * pdev PCI device whose resources are to be reserved

int bar BAR to be reserved

const char * res_name Name to be associated with resource

Description

Mark the PCI region associated with PCI device **pdev** BAR **bar** as being reserved by owner **res_name**. Do not access any address inside the PCI regions unless this call returns successfully.

Returns 0 on success, or EBUSY on error. A warning message is also printed on failure.

void **pci_release_selected_regions**(struct pci_dev * pdev, int bars)
Release selected PCI I/O and memory resources

Parameters

struct pci_dev * pdev PCI device whose resources were previously reserved

int bars Bitmask of BARs to be released

Description

Release selected PCI I/O and memory resources previously reserved. Call this function only after all use of the PCI regions has ceased.

int **pci_request_selected_regions**(struct pci_dev * pdev, int bars, const char * res_name)
Reserve selected PCI I/O and memory resources

Parameters

struct pci_dev * pdev PCI device whose resources are to be reserved

int bars Bitmask of BARs to be requested

const char * res_name Name to be associated with resource

void **pci_release_regions**(struct pci_dev * pdev)
Release reserved PCI I/O and memory resources

Parameters

struct pci_dev * pdev PCI device whose resources were previously reserved by pci_request_regions()

Description

Releases all PCI I/O and memory resources previously reserved by a successful call to pci_request_regions(). Call this function only after all use of the PCI regions has ceased.

int **pci_request_regions**(struct pci_dev * pdev, const char * res_name)
Reserve PCI I/O and memory resources

Parameters

struct pci_dev * pdev PCI device whose resources are to be reserved

const char * res_name Name to be associated with resource.

Description

Mark all PCI regions associated with PCI device **pdev** as being reserved by owner **res_name**. Do not access any address inside the PCI regions unless this call returns successfully.

Returns 0 on success, or EBUSY on error. A warning message is also printed on failure.

int **pci_request_regions_exclusive**(struct pci_dev * pdev, const char * res_name)
Reserve PCI I/O and memory resources

Parameters

struct pci_dev * pdev PCI device whose resources are to be reserved

const char * res_name Name to be associated with resource.

Description

Mark all PCI regions associated with PCI device **pdev** as being reserved by owner **res_name**. Do not access any address inside the PCI regions unless this call returns successfully.

pci_request_regions_exclusive() will mark the region so that /dev/mem and the sysfs MMIO access will not be allowed.

Returns 0 on success, or EBUSY on error. A warning message is also printed on failure.

int **pci_remap_iospace**(const struct resource * res, phys_addr_t phys_addr)
Remap the memory mapped I/O space

Parameters

const struct resource * res Resource describing the I/O space

phys_addr_t phys_addr physical address of range to be mapped

Description

Remap the memory mapped I/O space described by the **res** and the CPU physical address **phys_addr** into virtual address space. Only architectures that have memory mapped IO functions defined (and the PCI_IOBASE value defined) should call this function.

void **pci_unmap_iospace**(struct resource * res)
Unmap the memory mapped I/O space

Parameters

struct resource * res resource to be unmapped

Description

Unmap the CPU virtual address **res** from virtual address space. Only architectures that have memory mapped IO functions defined (and the PCI_IOBASE value defined) should call this function.

int **devm_pci_remap_iospace**(struct device * dev, const struct resource * res, phys_addr_t phys_addr)
Managed `pci_remap_iospace()`

Parameters

struct device * dev Generic device to remap IO address for

const struct resource * res Resource describing the I/O space

phys_addr_t phys_addr physical address of range to be mapped

Description

Managed `pci_remap_iospace()`. Map is automatically unmapped on driver detach.

void __iomem * **devm_pci_remap_cfgspace**(struct device * dev, resource_size_t offset, resource_size_t size)
Managed pci_remap_cfgspace()

Parameters

struct device * dev Generic device to remap IO address for

resource_size_t offset Resource address to map

resource_size_t size Size of map

Description

Managed pci_remap_cfgspace(). Map is automatically unmapped on driver detach.

void __iomem * **devm_pci_remap_cfg_resource**(struct device * dev, struct resource * res)
check, request region and ioremap cfg resource

Parameters

struct device * dev generic device to handle the resource for

struct resource * res configuration space resource to be handled

Description

Checks that a resource is a valid memory region, requests the memory region and ioremaps with pci_remap_cfgspace() API that ensures the proper PCI configuration space memory attributes are guaranteed.

All operations are managed and will be undone on driver detach.

Returns a pointer to the remapped memory or an ERR_PTR() encoded error code on failure. Usage example:

```
res = platform_get_resource(pdev, IORESOURCE_MEM, 0);
base = devm_pci_remap_cfg_resource(&pdev->dev, res);
if (IS_ERR(base))
        return PTR_ERR(base);
```

void **pci_set_master**(struct pci_dev * dev)
enables bus-mastering for device dev

Parameters

struct pci_dev * dev the PCI device to enable

Description

Enables bus-mastering on the device and calls pcibios_set_master() to do the needed arch specific settings.

void **pci_clear_master**(struct pci_dev * dev)
disables bus-mastering for device dev

Parameters

struct pci_dev * dev the PCI device to disable

int **pci_set_cacheline_size**(struct pci_dev * dev)
ensure the CACHE_LINE_SIZE register is programmed

Parameters

struct pci_dev * dev the PCI device for which MWI is to be enabled

Description

Helper function for pci_set_mwi. Originally copied from drivers/net/acenic.c. Copyright 1998-2001 by Jes Sorensen, <jes**trained**-monkey.org>.

Return

An appropriate -ERRNO error value on error, or zero for success.

int **pci_set_mwi**(struct pci_dev * dev)
enables memory-write-invalidate PCI transaction

Parameters

struct pci_dev * dev the PCI device for which MWI is enabled

Description

Enables the Memory-Write-Invalidate transaction in `PCI_COMMAND`.

Return

An appropriate -ERRNO error value on error, or zero for success.

int **pcim_set_mwi**(struct pci_dev * dev)
a device-managed `pci_set_mwi()`

Parameters

struct pci_dev * dev the PCI device for which MWI is enabled

Description

Managed `pci_set_mwi()`.

Return

An appropriate -ERRNO error value on error, or zero for success.

int **pci_try_set_mwi**(struct pci_dev * dev)
enables memory-write-invalidate PCI transaction

Parameters

struct pci_dev * dev the PCI device for which MWI is enabled

Description

Enables the Memory-Write-Invalidate transaction in `PCI_COMMAND`. Callers are not required to check the return value.

Return

An appropriate -ERRNO error value on error, or zero for success.

void **pci_clear_mwi**(struct pci_dev * dev)
disables Memory-Write-Invalidate for device dev

Parameters

struct pci_dev * dev the PCI device to disable

Description

Disables PCI Memory-Write-Invalidate transaction on the device

void **pci_intx**(struct pci_dev * pdev, int enable)
enables/disables PCI INTx for device dev

Parameters

struct pci_dev * pdev the PCI device to operate on

int enable boolean: whether to enable or disable PCI INTx

Description

Enables/disables PCI INTx for device **pdev**

bool **pci_check_and_mask_intx**(struct pci_dev * dev)
mask INTx on pending interrupt

Parameters

struct pci_dev * dev the PCI device to operate on

Description

Check if the device dev has its INTx line asserted, mask it and return true in that case. False is returned if no interrupt was pending.

bool **pci_check_and_unmask_intx**(struct pci_dev * dev)
unmask INTx if no interrupt is pending

Parameters

struct pci_dev * dev the PCI device to operate on

Description

Check if the device dev has its INTx line asserted, unmask it if not and return true. False is returned and the mask remains active if there was still an interrupt pending.

int **pci_wait_for_pending_transaction**(struct pci_dev * dev)
wait for pending transaction

Parameters

struct pci_dev * dev the PCI device to operate on

Description

Return 0 if transaction is pending 1 otherwise.

bool **pcie_has_flr**(struct pci_dev * dev)
check if a device supports function level resets

Parameters

struct pci_dev * dev device to check

Description

Returns true if the device advertises support for PCIe function level resets.

int **pcie_flr**(struct pci_dev * dev)
initiate a PCIe function level reset

Parameters

struct pci_dev * dev device to reset

Description

Initiate a function level reset on **dev**. The caller should ensure the device supports FLR before calling this function, e.g. by using the `pcie_has_flr()` helper.

int **pci_bridge_secondary_bus_reset**(struct pci_dev * dev)
Reset the secondary bus on a PCI bridge.

Parameters

struct pci_dev * dev Bridge device

Description

Use the bridge control register to assert reset on the secondary bus. Devices on the secondary bus are left in power-on state.

int **__pci_reset_function_locked**(struct pci_dev * dev)
reset a PCI device function while holding the **dev** mutex lock.

Parameters

struct pci_dev * dev PCI device to reset

Description

Some devices allow an individual function to be reset without affecting other functions in the same device. The PCI device must be responsive to PCI config space in order to use this function.

The device function is presumed to be unused and the caller is holding the device mutex lock when this function is called.

Resetting the device will make the contents of PCI configuration space random, so any caller of this must be prepared to reinitialise the device including MSI, bus mastering, BARs, decoding IO and memory spaces, etc.

Returns 0 if the device function was successfully reset or negative if the device doesn't support resetting a single function.

int **pci_reset_function**(struct pci_dev * dev)
quiesce and reset a PCI device function

Parameters

struct pci_dev * dev PCI device to reset

Description

Some devices allow an individual function to be reset without affecting other functions in the same device. The PCI device must be responsive to PCI config space in order to use this function.

This function does not just reset the PCI portion of a device, but clears all the state associated with the device. This function differs from `__pci_reset_function_locked()` in that it saves and restores device state over the reset and takes the PCI device lock.

Returns 0 if the device function was successfully reset or negative if the device doesn't support resetting a single function.

int **pci_reset_function_locked**(struct pci_dev * dev)
quiesce and reset a PCI device function

Parameters

struct pci_dev * dev PCI device to reset

Description

Some devices allow an individual function to be reset without affecting other functions in the same device. The PCI device must be responsive to PCI config space in order to use this function.

This function does not just reset the PCI portion of a device, but clears all the state associated with the device. This function differs from `__pci_reset_function_locked()` in that it saves and restores device state over the reset. It also differs from `pci_reset_function()` in that it requires the PCI device lock to be held.

Returns 0 if the device function was successfully reset or negative if the device doesn't support resetting a single function.

int **pci_try_reset_function**(struct pci_dev * dev)
quiesce and reset a PCI device function

Parameters

struct pci_dev * dev PCI device to reset

Description

Same as above, except return -EAGAIN if unable to lock device.

int **pci_probe_reset_slot**(struct pci_slot * slot)
probe whether a PCI slot can be reset

Parameters

struct pci_slot * slot PCI slot to probe

Description

Return 0 if slot can be reset, negative if a slot reset is not supported.

int **pci_probe_reset_bus**(struct pci_bus * bus)
probe whether a PCI bus can be reset

Parameters

struct pci_bus * bus PCI bus to probe

Description

Return 0 if bus can be reset, negative if a bus reset is not supported.

int **pci_reset_bus**(struct pci_dev * pdev)
Try to reset a PCI bus

Parameters

struct pci_dev * pdev top level PCI device to reset via slot/bus

Description

Same as above except return -EAGAIN if the bus cannot be locked

int **pcix_get_max_mmrbc**(struct pci_dev * dev)
get PCI-X maximum designed memory read byte count

Parameters

struct pci_dev * dev PCI device to query

Description

Returns mmrbc: maximum designed memory read count in bytes or appropriate error value.

int **pcix_get_mmrbc**(struct pci_dev * dev)
get PCI-X maximum memory read byte count

Parameters

struct pci_dev * dev PCI device to query

Description

Returns mmrbc: maximum memory read count in bytes or appropriate error value.

int **pcix_set_mmrbc**(struct pci_dev * dev, int mmrbc)
set PCI-X maximum memory read byte count

Parameters

struct pci_dev * dev PCI device to query

int mmrbc maximum memory read count in bytes valid values are 512, 1024, 2048, 4096

Description

If possible sets maximum memory read byte count, some bridges have errata that prevent this.

int **pcie_get_readrq**(struct pci_dev * dev)
get PCI Express read request size

Parameters

struct pci_dev * dev PCI device to query

Description

Returns maximum memory read request in bytes or appropriate error value.

int **pcie_set_readrq**(struct pci_dev * dev, int rq)
set PCI Express maximum memory read request

Parameters

struct pci_dev * dev PCI device to query

int rq maximum memory read count in bytes valid values are 128, 256, 512, 1024, 2048, 4096

Description

If possible sets maximum memory read request in bytes

int **pcie_get_mps**(struct pci_dev * dev)
get PCI Express maximum payload size

Parameters

struct pci_dev * dev PCI device to query

Description

Returns maximum payload size in bytes

int **pcie_set_mps**(struct pci_dev * dev, int mps)
set PCI Express maximum payload size

Parameters

struct pci_dev * dev PCI device to query

int mps maximum payload size in bytes valid values are 128, 256, 512, 1024, 2048, 4096

Description

If possible sets maximum payload size

u32 **pcie_bandwidth_available**(struct pci_dev * dev, struct pci_dev ** limiting_dev, enum pci_bus_speed * speed, enum pcie_link_width * width)
determine minimum link settings of a PCIe device and its bandwidth limitation

Parameters

struct pci_dev * dev PCI device to query

struct pci_dev ** limiting_dev storage for device causing the bandwidth limitation

enum pci_bus_speed * speed storage for speed of limiting device

enum pcie_link_width * width storage for width of limiting device

Description

Walk up the PCI device chain and find the point where the minimum bandwidth is available. Return the bandwidth available there and (if limiting_dev, speed, and width pointers are supplied) information about that point. The bandwidth returned is in Mb/s, i.e., megabits/second of raw bandwidth.

enum pci_bus_speed **pcie_get_speed_cap**(struct pci_dev * dev)
query for the PCI device's link speed capability

Parameters

struct pci_dev * dev PCI device to query

Description

Query the PCI device speed capability. Return the maximum link speed supported by the device.

enum pcie_link_width **pcie_get_width_cap**(struct pci_dev * dev)
query for the PCI device's link width capability

Parameters

struct pci_dev * dev PCI device to query

Description

Query the PCI device width capability. Return the maximum link width supported by the device.

void **pcie_print_link_status**(struct pci_dev * dev)
Report the PCI device's link speed and width

Parameters

struct pci_dev * dev PCI device to query

Description

Report the available bandwidth at the device.

int **pci_select_bars**(struct pci_dev * dev, unsigned long flags)
Make BAR mask from the type of resource

Parameters

struct pci_dev * dev the PCI device for which BAR mask is made

unsigned long flags resource type mask to be selected

Description

This helper routine makes bar mask from the type of resource.

int **pci_add_dynid**(struct pci_driver * drv, unsigned int vendor, unsigned int device, unsigned int subvendor, unsigned int subdevice, unsigned int class, unsigned int class_mask, unsigned long driver_data)
add a new PCI device ID to this driver and re-probe devices

Parameters

struct pci_driver * drv target pci driver

unsigned int vendor PCI vendor ID

unsigned int device PCI device ID

unsigned int subvendor PCI subvendor ID

unsigned int subdevice PCI subdevice ID

unsigned int class PCI class

unsigned int class_mask PCI class mask

unsigned long driver_data private driver data

Description

Adds a new dynamic pci device ID to this driver and causes the driver to probe for all devices again. **drv** must have been registered prior to calling this function.

Context

Does GFP_KERNEL allocation.

Return

0 on success, -errno on failure.

const struct pci_device_id * **pci_match_id**(const struct pci_device_id * ids, struct pci_dev * dev)
See if a pci device matches a given pci_id table

Parameters

const struct pci_device_id * ids array of PCI device id structures to search in

struct pci_dev * dev the PCI device structure to match against.

Description

Used by a driver to check whether a PCI device present in the system is in its list of supported devices. Returns the matching pci_device_id structure or `NULL` if there is no match.

Deprecated, don't use this as it will not catch any dynamic ids that a driver might want to check for.

int **__pci_register_driver**(struct pci_driver * drv, struct module * owner, const char * mod_name)
register a new pci driver

Parameters

struct pci_driver * drv the driver structure to register

struct module * owner owner module of drv

const char * mod_name module name string

Description

Adds the driver structure to the list of registered drivers. Returns a negative value on error, otherwise 0. If no error occurred, the driver remains registered even if no device was claimed during registration.

void **pci_unregister_driver**(struct pci_driver * drv)
unregister a pci driver

Parameters

struct pci_driver * drv the driver structure to unregister

Description

Deletes the driver structure from the list of registered PCI drivers, gives it a chance to clean up by calling its remove() function for each device it was responsible for, and marks those devices as driverless.

struct pci_driver * **pci_dev_driver**(const struct pci_dev * dev)
get the pci_driver of a device

Parameters

const struct pci_dev * dev the device to query

Description

Returns the appropriate pci_driver structure or NULL if there is no registered driver for the device.

struct pci_dev * **pci_dev_get**(struct pci_dev * dev)
increments the reference count of the pci device structure

Parameters

struct pci_dev * dev the device being referenced

Description

Each live reference to a device should be refcounted.

Drivers for PCI devices should normally record such references in their probe() methods, when they bind to a device, and release them by calling pci_dev_put(), in their disconnect() methods.

A pointer to the device with the incremented reference counter is returned.

void **pci_dev_put**(struct pci_dev * dev)
release a use of the pci device structure

Parameters

struct pci_dev * dev device that's been disconnected

Description

Must be called when a user of a device is finished with it. When the last user of the device calls this function, the memory of the device is freed.

void **pci_stop_and_remove_bus_device**(struct pci_dev * dev)
remove a PCI device and any children

Parameters

struct pci_dev * dev the device to remove

Description

Remove a PCI device from the device lists, informing the drivers that the device has been removed. We also remove any subordinate buses and children in a depth-first manner.

For each device we remove, delete the device structure from the device lists, remove the /proc entry, and notify userspace (/sbin/hotplug).

struct pci_bus * **pci_find_bus**(int domain, int busnr)
locate PCI bus from a given domain and bus number

Parameters

int domain number of PCI domain to search

int busnr number of desired PCI bus

Description

Given a PCI bus number and domain number, the desired PCI bus is located in the global list of PCI buses. If the bus is found, a pointer to its data structure is returned. If no bus is found, `NULL` is returned.

struct pci_bus * **pci_find_next_bus**(const struct pci_bus * from)
begin or continue searching for a PCI bus

Parameters

const struct pci_bus * from Previous PCI bus found, or `NULL` for new search.

Description

Iterates through the list of known PCI buses. A new search is initiated by passing `NULL` as the **from** argument. Otherwise if **from** is not `NULL`, searches continue from next device on the global list.

struct pci_dev * **pci_get_slot**(struct pci_bus * bus, unsigned int devfn)
locate PCI device for a given PCI slot

Parameters

struct pci_bus * bus PCI bus on which desired PCI device resides

unsigned int devfn encodes number of PCI slot in which the desired PCI device resides and the logical device number within that slot in case of multi-function devices.

Description

Given a PCI bus and slot/function number, the desired PCI device is located in the list of PCI devices. If the device is found, its reference count is increased and this function returns a pointer to its data structure. The caller must decrement the reference count by calling `pci_dev_put()`. If no device is found, `NULL` is returned.

struct pci_dev * **pci_get_domain_bus_and_slot**(int domain, unsigned int bus, unsigned int devfn)
locate PCI device for a given PCI domain (segment), bus, and slot

Parameters

int domain PCI domain/segment on which the PCI device resides.

unsigned int bus PCI bus on which desired PCI device resides

unsigned int devfn encodes number of PCI slot in which the desired PCI device resides and the logical device number within that slot in case of multi-function devices.

Description

Given a PCI domain, bus, and slot/function number, the desired PCI device is located in the list of PCI devices. If the device is found, its reference count is increased and this function returns a pointer to its data structure. The caller must decrement the reference count by calling `pci_dev_put()`. If no device is found, `NULL` is returned.

struct pci_dev * **pci_get_subsys**(unsigned int vendor, unsigned int device, unsigned int ss_vendor, unsigned int ss_device, struct pci_dev * from)
begin or continue searching for a PCI device by vendor/subvendor/device/subdevice id

Parameters

unsigned int vendor PCI vendor id to match, or `PCI_ANY_ID` to match all vendor ids

unsigned int device PCI device id to match, or `PCI_ANY_ID` to match all device ids

unsigned int ss_vendor PCI subsystem vendor id to match, or `PCI_ANY_ID` to match all vendor ids

unsigned int ss_device PCI subsystem device id to match, or `PCI_ANY_ID` to match all device ids

struct pci_dev * from Previous PCI device found in search, or `NULL` for new search.

Description

Iterates through the list of known PCI devices. If a PCI device is found with a matching **vendor**, **device**, **ss_vendor** and **ss_device**, a pointer to its device structure is returned, and the reference count to the device is incremented. Otherwise, `NULL` is returned. A new search is initiated by passing `NULL` as the **from** argument. Otherwise if **from** is not `NULL`, searches continue from next device on the global list. The reference count for **from** is always decremented if it is not `NULL`.

struct pci_dev * **pci_get_device**(unsigned int vendor, unsigned int device, struct pci_dev * from)
begin or continue searching for a PCI device by vendor/device id

Parameters

unsigned int vendor PCI vendor id to match, or PCI_ANY_ID to match all vendor ids

unsigned int device PCI device id to match, or PCI_ANY_ID to match all device ids

struct pci_dev * from Previous PCI device found in search, or NULL for new search.

Description

Iterates through the list of known PCI devices. If a PCI device is found with a matching **vendor** and **device**, the reference count to the device is incremented and a pointer to its device structure is returned. Otherwise, NULL is returned. A new search is initiated by passing NULL as the **from** argument. Otherwise if **from** is not NULL, searches continue from next device on the global list. The reference count for **from** is always decremented if it is not NULL.

struct pci_dev * **pci_get_class**(unsigned int class, struct pci_dev * from)
begin or continue searching for a PCI device by class

Parameters

unsigned int class search for a PCI device with this class designation

struct pci_dev * from Previous PCI device found in search, or NULL for new search.

Description

Iterates through the list of known PCI devices. If a PCI device is found with a matching **class**, the reference count to the device is incremented and a pointer to its device structure is returned. Otherwise, NULL is returned. A new search is initiated by passing NULL as the **from** argument. Otherwise if **from** is not NULL, searches continue from next device on the global list. The reference count for **from** is always decremented if it is not NULL.

int **pci_dev_present**(const struct pci_device_id * ids)
Returns 1 if device matching the device list is present, 0 if not.

Parameters

const struct pci_device_id * ids A pointer to a null terminated list of struct pci_device_id structures that describe the type of PCI device the caller is trying to find.

Description

Obvious fact: You do not have a reference to any device that might be found by this function, so if that device is removed from the system right after this function is finished, the value will be stale. Use this function to find devices that are usually built into a system, or for a general hint as to if another device happens to be present at this specific moment in time.

void **pci_msi_mask_irq**(struct irq_data * data)
Generic IRQ chip callback to mask PCI/MSI interrupts

Parameters

struct irq_data * data pointer to irqdata associated to that interrupt

void **pci_msi_unmask_irq**(struct irq_data * data)
Generic IRQ chip callback to unmask PCI/MSI interrupts

Parameters

struct irq_data * data pointer to irqdata associated to that interrupt

int **pci_msi_vec_count**(struct pci_dev * dev)
Return the number of MSI vectors a device can send

Parameters

struct pci_dev * dev device to report about

Description

This function returns the number of MSI vectors a device requested via Multiple Message Capable register. It returns a negative errno if the device is not capable sending MSI interrupts. Otherwise, the call succeeds and returns a power of two, up to a maximum of 2^5 (32), according to the MSI specification.

int **pci_msix_vec_count**(struct pci_dev * dev)
return the number of device's MSI-X table entries

Parameters

struct pci_dev * dev pointer to the pci_dev data structure of MSI-X device function This function returns the number of device's MSI-X table entries and therefore the number of MSI-X vectors device is capable of sending. It returns a negative errno if the device is not capable of sending MSI-X interrupts.

int **pci_msi_enabled**(void)
is MSI enabled?

Parameters

void no arguments

Description

Returns true if MSI has not been disabled by the command-line option pci=nomsi.

int **pci_enable_msix_range**(struct pci_dev * dev, struct msix_entry * entries, int minvec, int maxvec)
configure device's MSI-X capability structure

Parameters

struct pci_dev * dev pointer to the pci_dev data structure of MSI-X device function

struct msix_entry * entries pointer to an array of MSI-X entries

int minvec minimum number of MSI-X IRQs requested

int maxvec maximum number of MSI-X IRQs requested

Description

Setup the MSI-X capability structure of device function with a maximum possible number of interrupts in the range between **minvec** and **maxvec** upon its software

driver call to request for MSI-X mode enabled on its hardware device function. It returns a negative errno if an error occurs. If it succeeds, it returns the actual number of interrupts allocated and indicates the successful configuration of MSI-X capability structure with new allocated MSI-X interrupts.

int **pci_alloc_irq_vectors_affinity**(struct pci_dev * dev, unsigned int min_vecs, unsigned int max_vecs, unsigned int flags, struct irq_affinity * affd)
allocate multiple IRQs for a device

Parameters

struct pci_dev * dev PCI device to operate on

unsigned int min_vecs minimum number of vectors required (must be >= 1)

unsigned int max_vecs maximum (desired) number of vectors

unsigned int flags flags or quirks for the allocation

struct irq_affinity * affd optional description of the affinity requirements

Description

Allocate up to **max_vecs** interrupt vectors for **dev**, using MSI-X or MSI vectors if available, and fall back to a single legacy vector if neither is available. Return the number of vectors allocated, (which might be smaller than **max_vecs**) if successful, or a negative error code on error. If less than **min_vecs** interrupt vectors are available for **dev** the function will fail with -ENOSPC.

To get the Linux IRQ number used for a vector that can be passed to request_irq() use the `pci_irq_vector()` helper.

void **pci_free_irq_vectors**(struct pci_dev * dev)
free previously allocated IRQs for a device

Parameters

struct pci_dev * dev PCI device to operate on

Description

Undoes the allocations and enabling in pci_alloc_irq_vectors().

int **pci_irq_vector**(struct pci_dev * dev, unsigned int nr)
return Linux IRQ number of a device vector

Parameters

struct pci_dev * dev PCI device to operate on

unsigned int nr device-relative interrupt vector index (0-based).

const struct cpumask * **pci_irq_get_affinity**(struct pci_dev * dev, int nr)
return the affinity of a particular MSI vector

Parameters

struct pci_dev * dev PCI device to operate on

int nr device-relative interrupt vector index (0-based).

struct irq_domain * **pci_msi_create_irq_domain**(struct fwnode_handle * fwnode, struct msi_domain_info * info, struct irq_domain * parent)
Create a MSI interrupt domain

Parameters

struct fwnode_handle * fwnode Optional fwnode of the interrupt controller

struct msi_domain_info * info MSI domain info

struct irq_domain * parent Parent irq domain

Description

Updates the domain and chip ops and creates a MSI interrupt domain.

Return

A domain pointer or NULL in case of failure.

int **pci_bus_alloc_resource**(struct pci_bus * bus, struct resource * res, resource_size_t size, resource_size_t align, resource_size_t min, unsigned long type_mask, resource_size_t (*alignf)(void *, const struct resource *, resource_size_t, resource_size_t), void * alignf_data)
allocate a resource from a parent bus

Parameters

struct pci_bus * bus PCI bus

struct resource * res resource to allocate

resource_size_t size size of resource to allocate

resource_size_t align alignment of resource to allocate

resource_size_t min minimum /proc/iomem address to allocate

unsigned long type_mask IORESOURCE_* type flags

resource_size_t (*)(void *, const struct resource *, resource_size_t, resource_s
resource alignment function

void * alignf_data data argument for resource alignment function

Description

Given the PCI bus a device resides on, the size, minimum address, alignment and type, try to find an acceptable resource allocation for a specific device resource.

void **pci_bus_add_device**(struct pci_dev * dev)
start driver for a single device

Parameters

struct pci_dev * dev device to add

Description

This adds add sysfs entries and start device drivers

void **pci_bus_add_devices**(const struct pci_bus * bus)
start driver for PCI devices

Parameters

const struct pci_bus * bus bus to check for new devices

Description

Start driver for PCI devices and add some sysfs entries.

struct pci_ops * **pci_bus_set_ops**(struct pci_bus * bus, struct pci_ops * ops)
Set raw operations of pci bus

Parameters

struct pci_bus * bus pci bus struct

struct pci_ops * ops new raw operations

Description

Return previous raw operations

void **pci_cfg_access_lock**(struct pci_dev * dev)
Lock PCI config reads/writes

Parameters

struct pci_dev * dev pci device struct

Description

When access is locked, any userspace reads or writes to config space and concurrent lock requests will sleep until access is allowed via `pci_cfg_access_unlock()` again.

bool **pci_cfg_access_trylock**(struct pci_dev * dev)
try to lock PCI config reads/writes

Parameters

struct pci_dev * dev pci device struct

Description

Same as pci_cfg_access_lock, but will return 0 if access is already locked, 1 otherwise. This function can be used from atomic contexts.

void **pci_cfg_access_unlock**(struct pci_dev * dev)
Unlock PCI config reads/writes

Parameters

struct pci_dev * dev pci device struct

Description

This function allows PCI config accesses to resume.

enum pci_lost_interrupt_reason **pci_lost_interrupt**(struct pci_dev * pdev)
reports a lost PCI interrupt

Parameters

struct pci_dev * pdev device whose interrupt is lost

Description

The primary function of this routine is to report a lost interrupt in a standard way which users can recognise (instead of blaming the driver).

Return

a suggestion for fixing it (although the driver is not required to act on this).

int **pci_request_irq**(struct pci_dev * dev, unsigned int nr, irq_handler_t handler, irq_handler_t thread_fn, void * dev_id, const char * fmt, ...)
allocate an interrupt line for a PCI device

Parameters

struct pci_dev * dev PCI device to operate on

unsigned int nr device-relative interrupt vector index (0-based).

irq_handler_t handler Function to be called when the IRQ occurs. Primary handler for threaded interrupts. If NULL and thread_fn != NULL the default primary handler is installed.

irq_handler_t thread_fn Function called from the IRQ handler thread If NULL, no IRQ thread is created

void * dev_id Cookie passed back to the handler function

const char * fmt Printf-like format string naming the handler

... variable arguments

Description

This call allocates interrupt resources and enables the interrupt line and IRQ handling. From the point this call is made **handler** and **thread_fn** may be invoked. All interrupts requested using this function might be shared.

dev_id must not be NULL and must be globally unique.

void **pci_free_irq**(struct pci_dev * dev, unsigned int nr, void * dev_id)
free an interrupt allocated with pci_request_irq

Parameters

struct pci_dev * dev PCI device to operate on

unsigned int nr device-relative interrupt vector index (0-based).

void * dev_id Device identity to free

Description

Remove an interrupt handler. The handler is removed and if the interrupt line is no longer in use by any driver it is disabled. The caller must ensure the interrupt

is disabled on the device before calling this function. The function does not return until any executing interrupts for this IRQ have completed.

This function must not be called from interrupt context.

bool **pcie_relaxed_ordering_enabled**(struct pci_dev * dev)
Probe for PCIe relaxed ordering enable

Parameters

struct pci_dev * dev PCI device to query

Description

Returns true if the device has enabled relaxed ordering attribute.

int **pci_scan_slot**(struct pci_bus * bus, int devfn)
Scan a PCI slot on a bus for devices

Parameters

struct pci_bus * bus PCI bus to scan

int devfn slot number to scan (must have zero function)

Description

Scan a PCI slot on the specified PCI bus for devices, adding discovered devices to the **bus->devices** list. New devices will not have is_added set.

Returns the number of new devices found.

unsigned int **pci_scan_child_bus**(struct pci_bus * bus)
Scan devices below a bus

Parameters

struct pci_bus * bus Bus to scan for devices

Description

Scans devices below **bus** including subordinate buses. Returns new subordinate number including all the found devices.

unsigned int **pci_rescan_bus**(struct pci_bus * bus)
Scan a PCI bus for devices

Parameters

struct pci_bus * bus PCI bus to scan

Description

Scan a PCI bus and child buses for new devices, add them, and enable them.

Returns the max number of subordinate bus discovered.

struct pci_slot * **pci_create_slot**(struct pci_bus * parent, int slot_nr, const char * name, struct hotplug_slot * hotplug)
create or increment refcount for physical PCI slot

Parameters

struct pci_bus * parent struct pci_bus of parent bridge

int slot_nr PCI_SLOT(pci_dev->devfn) or -1 for placeholder

const char * name user visible string presented in /sys/bus/pci/slots/<name>

struct hotplug_slot * hotplug set if caller is hotplug driver, NULL otherwise

Description

PCI slots have first class attributes such as address, speed, width, and a `struct pci_slot` is used to manage them. This interface will either return a new `struct pci_slot` to the caller, or if the pci_slot already exists, its refcount will be incremented.

Slots are uniquely identified by a **pci_bus**, **slot_nr** tuple.

There are known platforms with broken firmware that assign the same name to multiple slots. Workaround these broken platforms by renaming the slots on behalf of the caller. If firmware assigns name N to multiple slots:

The first slot is assigned N The second slot is assigned N-1 The third slot is assigned N-2 etc.

Placeholder slots: In most cases, **pci_bus**, **slot_nr** will be sufficient to uniquely identify a slot. There is one notable exception - pSeries (rpaphp), where the **slot_nr** cannot be determined until a device is actually inserted into the slot. In this scenario, the caller may pass -1 for **slot_nr**.

The following semantics are imposed when the caller passes **slot_nr** == -1. First, we no longer check for an existing `struct` pci_slot, as there may be many slots with **slot_nr** of -1. The other change in semantics is user-visible, which is the 'address' parameter presented in sysfs will consist solely of a dddd:bb tuple, where dddd is the PCI domain of the `struct` pci_bus and bb is the bus number. In other words, the devfn of the 'placeholder' slot will not be displayed.

void **pci_destroy_slot**(struct pci_slot * slot)
decrement refcount for physical PCI slot

Parameters

struct pci_slot * slot struct pci_slot to decrement

Description

`struct` pci_slot is refcounted, so destroying them is really easy; we just call kobject_put on its kobj and let our release methods do the rest.

void **pci_hp_create_module_link**(struct pci_slot * pci_slot)
create symbolic link to the hotplug driver module.

Parameters

struct pci_slot * pci_slot struct pci_slot

Description

Helper function for pci_hotplug_core.c to create symbolic link to the hotplug driver module.

void **pci_hp_remove_module_link**(struct pci_slot * pci_slot)
remove symbolic link to the hotplug driver module.

Parameters

struct pci_slot * pci_slot struct pci_slot

Description

Helper function for pci_hotplug_core.c to remove symbolic link to the hotplug driver module.

int **pci_enable_rom**(struct pci_dev * pdev)
enable ROM decoding for a PCI device

Parameters

struct pci_dev * pdev PCI device to enable

Description

Enable ROM decoding on **dev**. This involves simply turning on the last bit of the PCI ROM BAR. Note that some cards may share address decoders between the ROM and other resources, so enabling it may disable access to MMIO registers or other card memory.

void **pci_disable_rom**(struct pci_dev * pdev)
disable ROM decoding for a PCI device

Parameters

struct pci_dev * pdev PCI device to disable

Description

Disable ROM decoding on a PCI device by turning off the last bit in the ROM BAR.

void __iomem * **pci_map_rom**(struct pci_dev * pdev, size_t * size)
map a PCI ROM to kernel space

Parameters

struct pci_dev * pdev pointer to pci device struct

size_t * size pointer to receive size of pci window over ROM

Return

kernel virtual pointer to image of ROM

Description

Map a PCI ROM into kernel space. If ROM is boot video ROM, the shadow BIOS copy will be returned instead of the actual ROM.

void **pci_unmap_rom**(struct pci_dev * pdev, void __iomem * rom)
unmap the ROM from kernel space

Parameters

struct pci_dev * pdev pointer to pci device struct

void __iomem * rom virtual address of the previous mapping

Description

Remove a mapping of a previously mapped ROM

int **pci_enable_sriov**(struct pci_dev * dev, int nr_virtfn)
enable the SR-IOV capability

Parameters

struct pci_dev * dev the PCI device

int nr_virtfn number of virtual functions to enable

Description

Returns 0 on success, or negative on failure.

void **pci_disable_sriov**(struct pci_dev * dev)
disable the SR-IOV capability

Parameters

struct pci_dev * dev the PCI device

int **pci_num_vf**(struct pci_dev * dev)
return number of VFs associated with a PF device_release_driver

Parameters

struct pci_dev * dev the PCI device

Description

Returns number of VFs, or 0 if SR-IOV is not enabled.

int **pci_vfs_assigned**(struct pci_dev * dev)
returns number of VFs are assigned to a guest

Parameters

struct pci_dev * dev the PCI device

Description

Returns number of VFs belonging to this device that are assigned to a guest. If device is not a physical function returns 0.

int **pci_sriov_set_totalvfs**(struct pci_dev * dev, u16 numvfs)

- reduce the TotalVFs available

Parameters

struct pci_dev * dev the PCI PF device

u16 numvfs number that should be used for TotalVFs supported

Description

Should be called from PF driver's probe routine with device's mutex held.

Returns 0 if PF is an SRIOV-capable device and value of numvfs valid. If not a PF return -ENOSYS; if numvfs is invalid return -EINVAL; if VFs already enabled, return -EBUSY.

int **pci_sriov_get_totalvfs**(struct pci_dev * dev)

- get total VFs supported on this device

Parameters

struct pci_dev * dev the PCI PF device

Description

For a PCIe device with SRIOV support, return the PCIe SRIOV capability value of TotalVFs or the value of driver_max_VFs if the driver reduced it. Otherwise 0.

int **pci_sriov_configure_simple**(struct pci_dev * dev, int nr_virtfn)
helper to configure SR-IOV

Parameters

struct pci_dev * dev the PCI device

int nr_virtfn number of virtual functions to enable, 0 to disable

Description

Enable or disable SR-IOV for devices that don't require any PF setup before enabling SR-IOV. Return value is negative on error, or number of VFs allocated on success.

ssize_t **pci_read_legacy_io**(struct file * filp, struct kobject * kobj, struct bin_attribute * bin_attr, char * buf, loff_t off, size_t count)
read byte(s) from legacy I/O port space

Parameters

struct file * filp open sysfs file

struct kobject * kobj kobject corresponding to file to read from

struct bin_attribute * bin_attr struct bin_attribute for this file

char * buf buffer to store results

loff_t off offset into legacy I/O port space

size_t count number of bytes to read

Description

Reads 1, 2, or 4 bytes from legacy I/O port space using an arch specific callback routine (pci_legacy_read).

ssize_t **pci_write_legacy_io**(struct file * filp, struct kobject * kobj, struct bin_attribute * bin_attr, char * buf, loff_t off, size_t count)
write byte(s) to legacy I/O port space

Parameters

struct file * filp open sysfs file

struct kobject * kobj kobject corresponding to file to read from

struct bin_attribute * bin_attr struct bin_attribute for this file

char * buf buffer containing value to be written

loff_t off offset into legacy I/O port space

size_t count number of bytes to write

Description

Writes 1, 2, or 4 bytes from legacy I/O port space using an arch specific callback routine (pci_legacy_write).

int **pci_mmap_legacy_mem**(struct file * filp, struct kobject * kobj, struct bin_attribute * attr, struct vm_area_struct * vma)
map legacy PCI memory into user memory space

Parameters

struct file * filp open sysfs file

struct kobject * kobj kobject corresponding to device to be mapped

struct bin_attribute * attr struct bin_attribute for this file

struct vm_area_struct * vma struct vm_area_struct passed to mmap

Description

Uses an arch specific callback, pci_mmap_legacy_mem_page_range, to mmap legacy memory space (first meg of bus space) into application virtual memory space.

int **pci_mmap_legacy_io**(struct file * filp, struct kobject * kobj, struct bin_attribute * attr, struct vm_area_struct * vma)
map legacy PCI IO into user memory space

Parameters

struct file * filp open sysfs file

struct kobject * kobj kobject corresponding to device to be mapped

struct bin_attribute * attr struct bin_attribute for this file

struct vm_area_struct * vma struct vm_area_struct passed to mmap

Description

Uses an arch specific callback, pci_mmap_legacy_io_page_range, to mmap legacy IO space (first meg of bus space) into application virtual memory space. Returns -ENOSYS if the operation isn't supported

void **pci_adjust_legacy_attr**(struct pci_bus * b, enum pci_mmap_state mmap_type)
adjustment of legacy file attributes

Parameters

struct pci_bus * b bus to create files under

enum pci_mmap_state mmap_type I/O port or memory

Description

Stub implementation. Can be overridden by arch if necessary.

void **pci_create_legacy_files**(struct pci_bus * b)
create legacy I/O port and memory files

Parameters

struct pci_bus * b bus to create files under

Description

Some platforms allow access to legacy I/O port and ISA memory space on a per-bus basis. This routine creates the files and ties them into their associated read, write and mmap files from pci-sysfs.c

On error unwind, but don't propagate the error to the caller as it is ok to set up the PCI bus without these files.

int **pci_mmap_resource**(struct kobject * kobj, struct bin_attribute * attr, struct vm_area_struct * vma, int write_combine)
map a PCI resource into user memory space

Parameters

struct kobject * kobj kobject for mapping

struct bin_attribute * attr struct bin_attribute for the file being mapped

struct vm_area_struct * vma struct vm_area_struct passed into the mmap

int write_combine 1 for write_combine mapping

Description

Use the regular PCI mapping routines to map a PCI resource into userspace.

void **pci_remove_resource_files**(struct pci_dev * pdev)
cleanup resource files

Parameters

struct pci_dev * pdev dev to cleanup

Description

If we created resource files for **pdev**, remove them from sysfs and free their resources.

int **pci_create_resource_files**(struct pci_dev * pdev)
create resource files in sysfs for **dev**

Parameters

struct pci_dev * pdev dev in question

Description

Walk the resources in **pdev** creating files for each resource available.

ssize_t **pci_write_rom**(struct file * filp, struct kobject * kobj, struct bin_attribute * bin_attr, char * buf, loff_t off, size_t count)
used to enable access to the PCI ROM display

Parameters

struct file * filp sysfs file

struct kobject * kobj kernel object handle

struct bin_attribute * bin_attr struct bin_attribute for this file

char * buf user input

loff_t off file offset

size_t count number of byte in input

Description

writing anything except 0 enables it

ssize_t **pci_read_rom**(struct file * filp, struct kobject * kobj, struct bin_attribute * bin_attr, char * buf, loff_t off, size_t count)
read a PCI ROM

Parameters

struct file * filp sysfs file

struct kobject * kobj kernel object handle

struct bin_attribute * bin_attr struct bin_attribute for this file

char * buf where to put the data we read from the ROM

loff_t off file offset

size_t count number of bytes to read

Description

Put **count** bytes starting at **off** into **buf** from the ROM in the PCI device corresponding to **kobj**.

void **pci_remove_sysfs_dev_files**(struct pci_dev * pdev)
cleanup PCI specific sysfs files

Parameters

struct pci_dev * pdev device whose entries we should free

Description

Cleanup when **pdev** is removed from sysfs.

22.2 PCI Hotplug Support Library

int **__pci_hp_register**(struct hotplug_slot * slot, struct pci_bus * bus, int devnr, const char * name, struct module * owner, const char * mod_name)
register a hotplug_slot with the PCI hotplug subsystem

Parameters

struct hotplug_slot * slot pointer to the `struct hotplug_slot` to register

struct pci_bus * bus bus this slot is on

int devnr device number

const char * name name registered with kobject core

struct module * owner caller module owner

const char * mod_name caller module name

Description

Prepares a hotplug slot for in-kernel use and immediately publishes it to user space in one go. Drivers may alternatively carry out the two steps separately by invoking pci_hp_initialize() and `pci_hp_add()`.

Returns 0 if successful, anything else for an error.

int **__pci_hp_initialize**(struct hotplug_slot * slot, struct pci_bus * bus, int devnr, const char * name, struct module * owner, const char * mod_name)
prepare hotplug slot for in-kernel use

Parameters

struct hotplug_slot * slot pointer to the `struct hotplug_slot` to initialize

struct pci_bus * bus bus this slot is on

int devnr slot number

const char * name name registered with kobject core

struct module * owner caller module owner

const char * mod_name caller module name

Description

Allocate and fill in a PCI slot for use by a hotplug driver. Once this has been called, the driver may invoke hotplug_slot_name() to get the slot's unique name. The driver must be prepared to handle a ->reset_slot callback from this point on.

Returns 0 on success or a negative int on error.

int **pci_hp_add**(struct hotplug_slot * slot)
publish hotplug slot to user space

Parameters

struct hotplug_slot * slot pointer to the `struct hotplug_slot` to publish

Description

Make a hotplug slot's sysfs interface available and inform user space of its addition by sending a uevent. The hotplug driver must be prepared to handle all `struct hotplug_slot_ops` callbacks from this point on.

Returns 0 on success or a negative int on error.

void **pci_hp_deregister**(struct hotplug_slot * slot)
deregister a hotplug_slot with the PCI hotplug subsystem

Parameters

struct hotplug_slot * slot pointer to the `struct hotplug_slot` to deregister

Description

The **slot** must have been registered with the pci hotplug subsystem previously with a call to pci_hp_register().

Returns 0 if successful, anything else for an error.

void **pci_hp_del**(struct hotplug_slot * slot)
unpublish hotplug slot from user space

Parameters

struct hotplug_slot * slot pointer to the `struct hotplug_slot` to unpublish

Description

Remove a hotplug slot's sysfs interface.

Returns 0 on success or a negative int on error.

void **pci_hp_destroy**(struct hotplug_slot * slot)
remove hotplug slot from in-kernel use

Parameters

struct hotplug_slot * slot pointer to the `struct hotplug_slot` to destroy

Description

Destroy a PCI slot used by a hotplug driver. Once this has been called, the driver may no longer invoke hotplug_slot_name() to get the slot's unique name. The driver no longer needs to handle a ->reset_slot callback from this point on.

Returns 0 on success or a negative int on error.

22.3 PCI Peer-to-Peer DMA Support

The PCI bus has pretty decent support for performing DMA transfers between two devices on the bus. This type of transaction is henceforth called Peer-to-Peer (or P2P). However, there are a number of issues that make P2P transactions tricky to do in a perfectly safe way.

One of the biggest issues is that PCI doesn't require forwarding transactions between hierarchy domains, and in PCIe, each Root Port defines a separate hierarchy domain. To make things worse, there is no simple way to determine if a given Root Complex supports this or not. (See PCIe r4.0, sec 1.3.1). Therefore, as of this writing, the kernel only supports doing P2P when the endpoints involved are all behind the same PCI bridge, as such devices are all in the same PCI hierarchy domain, and the spec guarantees that all transactions within the hierarchy will be routable, but it does not require routing between hierarchies.

The second issue is that to make use of existing interfaces in Linux, memory that is used for P2P transactions needs to be backed by struct pages. However, PCI BARs are not typically cache coherent so there are a few corner case gotchas with these pages so developers need to be careful about what they do with them.

22.3.1 Driver Writer's Guide

In a given P2P implementation there may be three or more different types of kernel drivers in play:

- Provider - A driver which provides or publishes P2P resources like memory or doorbell registers to other drivers.
- Client - A driver which makes use of a resource by setting up a DMA transaction to or from it.
- Orchestrator - A driver which orchestrates the flow of data between clients and providers.

In many cases there could be overlap between these three types (i.e., it may be typical for a driver to be both a provider and a client).

For example, in the NVMe Target Copy Offload implementation:

- The NVMe PCI driver is both a client, provider and orchestrator in that it exposes any CMB (Controller Memory Buffer) as a P2P memory resource (provider), it accepts P2P memory pages as buffers in requests to be used directly (client) and it can also make use of the CMB as submission queue entries (orchestrator).
- The RDMA driver is a client in this arrangement so that an RNIC can DMA directly to the memory exposed by the NVMe device.
- The NVMe Target driver (nvmet) can orchestrate the data from the RNIC to the P2P memory (CMB) and then to the NVMe device (and vice versa).

This is currently the only arrangement supported by the kernel but one could imagine slight tweaks to this that would allow for the same functionality. For example, if a specific RNIC added a BAR with some memory behind it, its driver could add support as a P2P provider and then the NVMe Target could use the RNIC's memory instead of the CMB in cases where the NVMe cards in use do not have CMB support.

Provider Drivers

A provider simply needs to register a BAR (or a portion of a BAR) as a P2P DMA resource using `pci_p2pdma_add_resource()`. This will register struct pages for all the specified memory.

After that it may optionally publish all of its resources as P2P memory using `pci_p2pmem_publish()`. This will allow any orchestrator drivers to find and use the memory. When marked in this way, the resource must be regular memory with no side effects.

For the time being this is fairly rudimentary in that all resources are typically going to be P2P memory. Future work will likely expand this to include other types of resources like doorbells.

Client Drivers

A client driver typically only has to conditionally change its DMA map routine to use the mapping function `pci_p2pdma_map_sg()` instead of the usual `dma_map_sg()` function. Memory mapped in this way does not need to be unmapped.

The client may also, optionally, make use of `is_pci_p2pdma_page()` to determine when to use the P2P mapping functions and when to use the regular mapping functions. In some situations, it may be more appropriate to use a flag to indicate a given request is P2P memory and map appropriately. It is important to ensure that struct pages that back P2P memory stay out of code that does not have support for them as other code may treat the pages as regular memory which may not be appropriate.

Orchestrator Drivers

The first task an orchestrator driver must do is compile a list of all client devices that will be involved in a given transaction. For example, the NVMe Target driver creates a list including the namespace block device and the RNIC in use. If the orchestrator has access to a specific P2P provider to use it may check compatibility using `pci_p2pdma_distance()` otherwise it may find a memory provider that's compatible with all clients using `pci_p2pmem_find()`. If more than one provider is supported, the one nearest to all the clients will be chosen first. If more than one provider is an equal distance away, the one returned will be chosen at random (it is not an arbitrary but truly random). This function returns the PCI device to use for the provider with a reference taken and therefore when it's no longer needed it should be returned with `pci_dev_put()`.

Once a provider is selected, the orchestrator can then use `pci_alloc_p2pmem()` and `pci_free_p2pmem()` to allocate P2P memory from the provider. `pci_p2pmem_alloc_sgl()` and `pci_p2pmem_free_sgl()` are convenience functions for allocating scatter-gather lists with P2P memory.

Struct Page Caveats

Driver writers should be very careful about not passing these special struct pages to code that isn't prepared for it. At this time, the kernel interfaces do not have any checks for ensuring this. This obviously precludes passing these pages to userspace.

P2P memory is also technically IO memory but should never have any side effects behind it. Thus, the order of loads and stores should not be important and ioreadX(), iowriteX() and friends should not be necessary.

22.3.2 P2P DMA Support Library

int **pci_p2pdma_add_resource**(struct pci_dev * pdev, int bar, size_t size, u64 offset)
add memory for use as p2p memory

Parameters

struct pci_dev * pdev the device to add the memory to

int bar PCI BAR to add

size_t size size of the memory to add, may be zero to use the whole BAR

u64 offset offset into the PCI BAR

Description

The memory will be given ZONE_DEVICE struct pages so that it may be used with any DMA request.

int **pci_p2pdma_distance_many**(struct pci_dev * provider, struct device ** clients, int num_clients, bool verbose)
Determine the cumulative distance between a p2pdma provider and the clients in use.

Parameters

struct pci_dev * provider p2pdma provider to check against the client list

struct device ** clients array of devices to check (NULL-terminated)

int num_clients number of clients in the array

bool verbose if true, print warnings for devices when we return -1

Description

Returns -1 if any of the clients are not compatible, otherwise returns a positive number where a lower number is the preferable choice. (If there's one client that's the same as the provider it will return 0, which is best choice).

"compatible" means the provider and the clients are either all behind the same PCI root port or the host bridges connected to each of the devices are listed in the 'pci_p2pdma_whitelist'.

bool **pci_has_p2pmem**(struct pci_dev * pdev)
check if a given PCI device has published any p2pmem

Parameters

struct pci_dev * pdev PCI device to check

struct pci_dev * **pci_p2pmem_find_many**(struct device ** clients, int num_clients)
find a peer-to-peer DMA memory device compatible with the specified list of clients and shortest distance (as determined by pci_p2pmem_dma())

Parameters

struct device ** clients array of devices to check (NULL-terminated)

int num_clients number of client devices in the list

Description

If multiple devices are behind the same switch, the one "closest" to the client devices in use will be chosen first. (So if one of the providers is the same as one of the clients, that provider will be used ahead of any other providers that are unrelated). If multiple providers are an equal distance away, one will be chosen at random.

Returns a pointer to the PCI device with a reference taken (use pci_dev_put to return the reference) or NULL if no compatible device is found. The found provider will also be assigned to the client list.

void * **pci_alloc_p2pmem**(struct pci_dev * pdev, size_t size)
allocate peer-to-peer DMA memory

Parameters

struct pci_dev * pdev the device to allocate memory from

size_t size number of bytes to allocate

Description

Returns the allocated memory or NULL on error.

void **pci_free_p2pmem**(struct pci_dev * pdev, void * addr, size_t size)
free peer-to-peer DMA memory

Parameters

struct pci_dev * pdev the device the memory was allocated from

void * addr address of the memory that was allocated

size_t size number of bytes that were allocated

pci_bus_addr_t **pci_p2pmem_virt_to_bus**(struct pci_dev * pdev, void * addr)
return the PCI bus address for a given virtual address obtained with `pci_alloc_p2pmem()`

Parameters

struct pci_dev * pdev the device the memory was allocated from

void * addr address of the memory that was allocated

struct scatterlist * **pci_p2pmem_alloc_sgl**(struct pci_dev * pdev, unsigned int * nents, u32 length)
allocate peer-to-peer DMA memory in a scatterlist

Parameters

struct pci_dev * pdev the device to allocate memory from

unsigned int * nents the number of SG entries in the list

u32 length number of bytes to allocate

Return

`NULL` on error or `struct scatterlist` pointer and **nents** on success

void **pci_p2pmem_free_sgl**(struct pci_dev * pdev, struct scatterlist * sgl)
free a scatterlist allocated by `pci_p2pmem_alloc_sgl()`

Parameters

struct pci_dev * pdev the device to allocate memory from

struct scatterlist * sgl the allocated scatterlist

void **pci_p2pmem_publish**(struct pci_dev * pdev, bool publish)
publish the peer-to-peer DMA memory for use by other devices with pci_p2pmem_find()

Parameters

struct pci_dev * pdev the device with peer-to-peer DMA memory to publish

bool publish set to true to publish the memory, false to unpublish it

Description

Published memory can be used by other PCI device drivers for peer-2-peer DMA operations. Non-published memory is reserved for exclusive use of the device driver that registers the peer-to-peer memory.

int **pci_p2pdma_map_sg_attrs**(struct device * dev, struct scatterlist * sg, int nents, enum dma_data_direction dir, unsigned long attrs)
map a PCI peer-to-peer scatterlist for DMA

Parameters

struct device * dev device doing the DMA request

struct scatterlist * sg scatter list to map

int nents elements in the scatterlist

enum dma_data_direction dir DMA direction

unsigned long attrs DMA attributes passed to dma_map_sg() (if called)

Description

Scatterlists mapped with this function should be unmapped using `pci_p2pdma_unmap_sg_attrs()`.

Returns the number of SG entries mapped or 0 on error.

void **pci_p2pdma_unmap_sg_attrs**(struct device * dev, struct scatterlist * sg, int nents, enum dma_data_direction dir, unsigned long attrs)
unmap a PCI peer-to-peer scatterlist that was mapped with pci_p2pdma_map_sg()

Parameters

struct device * dev device doing the DMA request

struct scatterlist * sg scatter list to map

int nents number of elements returned by pci_p2pdma_map_sg()

enum dma_data_direction dir DMA direction

unsigned long attrs DMA attributes passed to dma_unmap_sg() (if called)

int **pci_p2pdma_enable_store**(const char * page, struct pci_dev ** p2p_dev, bool * use_p2pdma)
parse a configfs/sysfs attribute store to enable p2pdma

Parameters

const char * page contents of the value to be stored

struct pci_dev ** p2p_dev returns the PCI device that was selected to be used (if one was specified in the stored value)

bool * use_p2pdma returns whether to enable p2pdma or not

Description

Parses an attribute value to decide whether to enable p2pdma. The value can select a PCI device (using its full BDF device name) or a boolean (in any format strtobool() accepts). A false value disables p2pdma, a true value expects the caller to automatically find a compatible device and specifying a PCI device expects the caller to use the specific provider.

`pci_p2pdma_enable_show()` should be used as the show operation for the attribute.

Returns 0 on success

ssize_t **pci_p2pdma_enable_show**(char * page, struct pci_dev * p2p_dev, bool use_p2pdma)
show a configfs/sysfs attribute indicating whether p2pdma is enabled

Parameters

char * page contents of the stored value

struct pci_dev * p2p_dev the selected p2p device (NULL if no device is selected)

bool use_p2pdma whether p2pdma has been enabled

Description

Attributes that use `pci_p2pdma_enable_store()` should use this function to show the value of the attribute.

Returns 0 on success

CHAPTER

TWENTYTHREE

SERIAL PERIPHERAL INTERFACE (SPI)

SPI is the "Serial Peripheral Interface", widely used with embedded systems because it is a simple and efficient interface: basically a multiplexed shift register. Its three signal wires hold a clock (SCK, often in the range of 1-20 MHz), a "Master Out, Slave In" (MOSI) data line, and a "Master In, Slave Out" (MISO) data line. SPI is a full duplex protocol; for each bit shifted out the MOSI line (one per clock) another is shifted in on the MISO line. Those bits are assembled into words of various sizes on the way to and from system memory. An additional chipselect line is usually active-low (nCS); four signals are normally used for each peripheral, plus sometimes an interrupt.

The SPI bus facilities listed here provide a generalized interface to declare SPI busses and devices, manage them according to the standard Linux driver model, and perform input/output operations. At this time, only "master" side interfaces are supported, where Linux talks to SPI peripherals and does not implement such a peripheral itself. (Interfaces to support implementing SPI slaves would necessarily look different.)

The programming interface is structured around two kinds of driver, and two kinds of device. A "Controller Driver" abstracts the controller hardware, which may be as simple as a set of GPIO pins or as complex as a pair of FIFOs connected to dual DMA engines on the other side of the SPI shift register (maximizing throughput). Such drivers bridge between whatever bus they sit on (often the platform bus) and SPI, and expose the SPI side of their device as a `struct spi_master`. SPI devices are children of that master, represented as a `struct spi_device` and manufactured from `struct spi_board_info` descriptors which are usually provided by board-specific initialization code. A `struct spi_driver` is called a "Protocol Driver", and is bound to a spi_device using normal driver model calls.

The I/O model is a set of queued messages. Protocol drivers submit one or more `struct spi_message` objects, which are processed and completed asynchronously. (There are synchronous wrappers, however.) Messages are built from one or more `struct spi_transfer` objects, each of which wraps a full duplex SPI transfer. A variety of protocol tweaking options are needed, because different chips adopt very different policies for how they use the bits transferred with SPI.

struct **spi_statistics**
    statistics for spi transfers

Definition

```
struct spi_statistics {
  spinlock_t lock;
  unsigned long           messages;
  unsigned long           transfers;
  unsigned long           errors;
  unsigned long           timedout;
  unsigned long           spi_sync;
  unsigned long           spi_sync_immediate;
  unsigned long           spi_async;
  unsigned long long      bytes;
  unsigned long long      bytes_rx;
  unsigned long long      bytes_tx;
#define SPI_STATISTICS_HISTO_SIZE 17;
  unsigned long transfer_bytes_histo[SPI_STATISTICS_HISTO_SIZE];
  unsigned long transfers_split_maxsize;
};
```

Members

lock lock protecting this structure

messages number of spi-messages handled

transfers number of spi_transfers handled

errors number of errors during spi_transfer

timedout number of timeouts during spi_transfer

spi_sync number of times spi_sync is used

spi_sync_immediate number of times spi_sync is executed immediately in calling context without queuing and scheduling

spi_async number of times spi_async is used

bytes number of bytes transferred to/from device

bytes_rx number of bytes received from device

bytes_tx number of bytes sent to device

transfer_bytes_histo transfer bytes histogramm

transfers_split_maxsize number of transfers that have been split because of maxsize limit

struct **spi_delay**
SPI delay information

Definition

```
struct spi_delay {
#define SPI_DELAY_UNIT_USECS    0;
#define SPI_DELAY_UNIT_NSECS    1;
#define SPI_DELAY_UNIT_SCK      2;
  u16 value;
  u8 unit;
};
```

Members

value Value for the delay

unit Unit for the delay

struct **spi_device**
Controller side proxy for an SPI slave device

Definition

```
struct spi_device {
  struct device           dev;
  struct spi_controller   *controller;
  struct spi_controller   *master;
  u32 max_speed_hz;

#define SPI_LOOP        0x20                    ;
#define SPI_NO_CS       0x40                    ;
#define SPI_READY       0x80                    ;
#define SPI_TX_DUAL     0x100                   ;
#define SPI_TX_QUAD     0x200                   ;
#define SPI_RX_DUAL     0x400                   ;
#define SPI_RX_QUAD     0x800                   ;
#define SPI_CS_WORD     0x1000                  ;
#define SPI_TX_OCTAL    0x2000                  ;
#define SPI_RX_OCTAL    0x4000                  ;
#define SPI_3WIRE_HIZ   0x8000                  ;
  int irq;
  void *controller_state;
  void *controller_data;
  char modalias[SPI_NAME_SIZE];
  const char              *driver_override;
  int cs_gpio;
  struct gpio_desc        *cs_gpiod;
  struct spi_delay        word_delay;
  struct spi_statistics   statistics;
};
```

Members

dev Driver model representation of the device.

controller SPI controller used with the device.

master Copy of controller, for backwards compatibility.

max_speed_hz Maximum clock rate to be used with this chip (on this board); may be changed by the device's driver. The spi_transfer.speed_hz can override this for each transfer.

chip_select Chipselect, distinguishing chips handled by **controller**.

bits_per_word Data transfers involve one or more words; word sizes like eight or 12 bits are common. In-memory wordsizes are powers of two bytes (e.g. 20 bit samples use 32 bits). This may be changed by the device's driver, or left at the default (0) indicating protocol words are eight bit bytes. The spi_transfer.bits_per_word can override this for each transfer.

rt Make the pump thread real time priority.

mode The spi mode defines how data is clocked out and in. This may be changed by the device's driver. The "active low" default for chipselect mode can be overridden (by specifying SPI_CS_HIGH) as can the "MSB first" default for each word in a transfer (by specifying SPI_LSB_FIRST).

irq Negative, or the number passed to request_irq() to receive interrupts from this device.

controller_state Controller's runtime state

controller_data Board-specific definitions for controller, such as FIFO initialization parameters; from board_info.controller_data

modalias Name of the driver to use with this device, or an alias for that name. This appears in the sysfs "modalias" attribute for driver coldplugging, and in uevents used for hotplugging

driver_override If the name of a driver is written to this attribute, then the device will bind to the named driver and only the named driver.

cs_gpio LEGACY: gpio number of the chipselect line (optional, -ENOENT when not using a GPIO line) use cs_gpiod in new drivers by opting in on the spi_master.

cs_gpiod gpio descriptor of the chipselect line (optional, NULL when not using a GPIO line)

word_delay delay to be inserted between consecutive words of a transfer

statistics statistics for the spi_device

Description

A **spi_device** is used to interchange data between an SPI slave (usually a discrete chip) and CPU memory.

In **dev**, the platform_data is used to hold information about this device that's meaningful to the device's protocol driver, but not to its controller. One example might be an identifier for a chip variant with slightly different functionality; another might be information about how this particular board wires the chip's pins.

struct **spi_driver**
Host side "protocol" driver

Definition

```
struct spi_driver {
  const struct spi_device_id *id_table;
```

(continues on next page)

(continued from previous page)

```
  int (*probe)(struct spi_device *spi);
  int (*remove)(struct spi_device *spi);
  void (*shutdown)(struct spi_device *spi);
  struct device_driver    driver;
};
```

Members

id_table List of SPI devices supported by this driver

probe Binds this driver to the spi device. Drivers can verify that the device is actually present, and may need to configure characteristics (such as bits_per_word) which weren't needed for the initial configuration done during system setup.

remove Unbinds this driver from the spi device

shutdown Standard shutdown callback used during system state transitions such as powerdown/halt and kexec

driver SPI device drivers should initialize the name and owner field of this structure.

Description

This represents the kind of device driver that uses SPI messages to interact with the hardware at the other end of a SPI link. It's called a "protocol" driver because it works through messages rather than talking directly to SPI hardware (which is what the underlying SPI controller driver does to pass those messages). These protocols are defined in the specification for the device(s) supported by the driver.

As a rule, those device protocols represent the lowest level interface supported by a driver, and it will support upper level interfaces too. Examples of such upper levels include frameworks like MTD, networking, MMC, RTC, filesystem character device nodes, and hardware monitoring.

void **spi_unregister_driver**(struct spi_driver * sdrv)
reverse effect of spi_register_driver

Parameters

struct spi_driver * sdrv the driver to unregister

Context

can sleep

module_spi_driver(__spi_driver)
Helper macro for registering a SPI driver

Parameters

__spi_driver spi_driver struct

Description

Helper macro for SPI drivers which do not do anything special in module init/exit. This eliminates a lot of boilerplate. Each module may only use this macro once, and calling it replaces `module_init()` and `module_exit()`

struct **spi_controller**
interface to SPI master or slave controller

Definition

```
struct spi_controller {
  struct device   dev;

};
```

Members

dev device interface to this driver

list link with the global spi_controller list

bus_num board-specific (and often SOC-specific) identifier for a given SPI controller.

num_chipselect chipselects are used to distinguish individual SPI slaves, and are numbered from zero to num_chipselects. each slave has a chipselect signal, but it' s common that not every chipselect is connected to a slave.

dma_alignment SPI controller constraint on DMA buffers alignment.

mode_bits flags understood by this controller driver

bits_per_word_mask A mask indicating which values of bits_per_word are supported by the driver. Bit n indicates that a bits_per_word n+1 is supported. If set, the SPI core will reject any transfer with an unsupported bits_per_word. If not set, this value is simply ignored, and it' s up to the individual driver to perform any validation.

min_speed_hz Lowest supported transfer speed

max_speed_hz Highest supported transfer speed

flags other constraints relevant to this driver

slave indicates that this is an SPI slave controller

max_transfer_size function that returns the max transfer size for a `spi_device`; may be `NULL`, so the default `SIZE_MAX` will be used.

max_message_size function that returns the max message size for a `spi_device`; may be `NULL`, so the default `SIZE_MAX` will be used.

io_mutex mutex for physical bus access

bus_lock_spinlock spinlock for SPI bus locking

bus_lock_mutex mutex for exclusion of multiple callers

bus_lock_flag indicates that the SPI bus is locked for exclusive use

setup updates the device mode and clocking records used by a device's SPI controller; protocol code may call this. This must fail if an unrecognized or unsupported mode is requested. It's always safe to call this unless transfers are pending on the device whose settings are being modified.

set_cs_timing optional hook for SPI devices to request SPI master controller for configuring specific CS setup time, hold time and inactive delay interms of clock counts

transfer adds a message to the controller's transfer queue.

cleanup frees controller-specific state

can_dma determine whether this controller supports DMA

queued whether this controller is providing an internal message queue

kworker thread struct for message pump

kworker_task pointer to task for message pump kworker thread

pump_messages work struct for scheduling work to the message pump

queue_lock spinlock to syncronise access to message queue

queue message queue

cur_msg the currently in-flight message

idling the device is entering idle state

busy message pump is busy

running message pump is running

rt whether this queue is set to run as a realtime task

auto_runtime_pm the core should ensure a runtime PM reference is held while the hardware is prepared, using the parent device for the spidev

cur_msg_prepared spi_prepare_message was called for the currently in-flight message

cur_msg_mapped message has been mapped for DMA

xfer_completion used by core transfer_one_message()

max_dma_len Maximum length of a DMA transfer for the device.

prepare_transfer_hardware a message will soon arrive from the queue so the subsystem requests the driver to prepare the transfer hardware by issuing this call

transfer_one_message the subsystem calls the driver to transfer a single message while queuing transfers that arrive in the meantime. When the driver is finished with this message, it must call `spi_finalize_current_message()` so the subsystem can issue the next message

unprepare_transfer_hardware there are currently no more messages on the queue so the subsystem notifies the driver that it may relax the hardware by issuing this call

prepare_message set up the controller to transfer a single message, for example doing DMA mapping. Called from threaded context.

unprepare_message undo any work done by prepare_message().

slave_abort abort the ongoing transfer request on an SPI slave controller

set_cs set the logic level of the chip select line. May be called from interrupt context.

transfer_one transfer a single spi_transfer.

- return 0 if the transfer is finished,
- return 1 if the transfer is still in progress. When the driver is finished with this transfer it must call `spi_finalize_current_transfer()` so the subsystem can issue the next transfer. Note: transfer_one and transfer_one_message are mutually exclusive; when both are set, the generic subsystem does not call your transfer_one callback.

handle_err the subsystem calls the driver to handle an error that occurs in the generic implementation of transfer_one_message().

mem_ops optimized/dedicated operations for interactions with SPI memory. This field is optional and should only be implemented if the controller has native support for memory like operations.

cs_setup delay to be introduced by the controller after CS is asserted

cs_hold delay to be introduced by the controller before CS is deasserted

cs_inactive delay to be introduced by the controller after CS is deasserted. If **cs_change_delay** is used from **spi_transfer**, then the two delays will be added up.

cs_gpios LEGACY: array of GPIO descs to use as chip select lines; one per CS number. Any individual value may be -ENOENT for CS lines that are not GPIOs (driven by the SPI controller itself). Use the cs_gpiods in new drivers.

cs_gpiods Array of GPIO descs to use as chip select lines; one per CS number. Any individual value may be NULL for CS lines that are not GPIOs (driven by the SPI controller itself).

use_gpio_descriptors Turns on the code in the SPI core to parse and grab GPIO descriptors rather than using global GPIO numbers grabbed by the driver. This will fill in **cs_gpiods** and **cs_gpios** should not be used, and SPI devices will have the cs_gpiod assigned rather than cs_gpio.

unused_native_cs When cs_gpiods is used, `spi_register_controller()` will fill in this field with the first unused native CS, to be used by SPI controller drivers that need to drive a native CS when using GPIO CS.

max_native_cs When cs_gpiods is used, and this field is filled in, `spi_register_controller()` will validate all native CS (including the unused native CS) against this value.

statistics statistics for the spi_controller

dma_tx DMA transmit channel

dma_rx DMA receive channel

dummy_rx dummy receive buffer for full-duplex devices

dummy_tx dummy transmit buffer for full-duplex devices

fw_translate_cs If the boot firmware uses different numbering scheme what Linux expects, this optional hook can be used to translate between the two.

ptp_sts_supported If the driver sets this to true, it must provide a time snapshot in **spi_transfer->ptp_sts** as close as possible to the moment in time when **spi_transfer->ptp_sts_word_pre** and **spi_transfer->ptp_sts_word_post** were transmitted. If the driver does not set this, the SPI core takes the snapshot as close to the driver hand-over as possible.

irq_flags Interrupt enable state during PTP system timestamping

Description

Each SPI controller can communicate with one or more **spi_device** children. These make a small bus, sharing MOSI, MISO and SCK signals but not chip select signals. Each device may be configured to use a different clock rate, since those shared signals are ignored unless the chip is selected.

The driver for an SPI controller manages access to those devices through a queue of spi_message transactions, copying data between CPU memory and an SPI slave device. For each such message it queues, it calls the message' s completion function when the transaction completes.

struct **spi_res**
spi resource management structure

Definition

```
struct spi_res {
  struct list_head        entry;
  spi_res_release_t release;
  unsigned long long      data[];
};
```

Members

entry list entry

release release code called prior to freeing this resource

data extra data allocated for the specific use-case

Description

this is based on ideas from devres, but focused on life-cycle management during spi_message processing

struct **spi_transfer**
a read/write buffer pair

Definition

```
struct spi_transfer {
  const void      *tx_buf;
  void *rx_buf;
  unsigned len;
  dma_addr_t tx_dma;
  dma_addr_t rx_dma;
  struct sg_table tx_sg;
  struct sg_table rx_sg;
  unsigned cs_change:1;
  unsigned tx_nbits:3;
  unsigned rx_nbits:3;
#define SPI_NBITS_SINGLE        0x01 ;
#define SPI_NBITS_DUAL          0x02 ;
#define SPI_NBITS_QUAD          0x04 ;
  u8 bits_per_word;
  u16 delay_usecs;
  struct spi_delay        delay;
  struct spi_delay        cs_change_delay;
  struct spi_delay        word_delay;
  u32 speed_hz;
  u32 effective_speed_hz;
  unsigned int    ptp_sts_word_pre;
  unsigned int    ptp_sts_word_post;
  struct ptp_system_timestamp *ptp_sts;
  bool timestamped;
  struct list_head transfer_list;
};
```

Members

tx_buf data to be written (dma-safe memory), or NULL

rx_buf data to be read (dma-safe memory), or NULL

len size of rx and tx buffers (in bytes)

tx_dma DMA address of tx_buf, if **spi_message.is_dma_mapped**

rx_dma DMA address of rx_buf, if **spi_message.is_dma_mapped**

tx_sg Scatterlist for transmit, currently not for client use

rx_sg Scatterlist for receive, currently not for client use

cs_change affects chipselect after this transfer completes

tx_nbits number of bits used for writing. If 0 the default (SPI_NBITS_SINGLE) is used.

rx_nbits number of bits used for reading. If 0 the default (SPI_NBITS_SINGLE) is used.

bits_per_word select a bits_per_word other than the device default for this transfer. If 0 the default (from **spi_device**) is used.

delay_usecs microseconds to delay after this transfer before (optionally) changing the chipselect status, then starting the next transfer or completing this **spi_message**.

delay delay to be introduced after this transfer before (optionally) changing the chipselect status, then starting the next transfer or completing this **spi_message**.

cs_change_delay delay between cs deassert and assert when **cs_change** is set and **spi_transfer** is not the last in **spi_message**

word_delay inter word delay to be introduced after each word size (set by bits_per_word) transmission.

speed_hz Select a speed other than the device default for this transfer. If 0 the default (from **spi_device**) is used.

effective_speed_hz the effective SCK-speed that was used to transfer this transfer. Set to 0 if the spi bus driver does not support it.

ptp_sts_word_pre The word (subject to bits_per_word semantics) offset within **tx_buf** for which the SPI device is requesting that the time snapshot for this transfer begins. Upon completing the SPI transfer, this value may have changed compared to what was requested, depending on the available snapshotting resolution (DMA transfer, **ptp_sts_supported** is false, etc).

ptp_sts_word_post See **ptp_sts_word_post**. The two can be equal (meaning that a single byte should be snapshotted). If the core takes care of the timestamp (if **ptp_sts_supported** is false for this controller), it will set **ptp_sts_word_pre** to 0, and **ptp_sts_word_post** to the length of the transfer. This is done purposefully (instead of setting to spi_transfer->len - 1) to denote that a transfer-level snapshot taken from within the driver may still be of higher quality.

ptp_sts Pointer to a memory location held by the SPI slave device where a PTP system timestamp structure may lie. If drivers use PIO or their hardware has some sort of assist for retrieving exact transfer timing, they can (and should) assert **ptp_sts_supported** and populate this structure using the ptp_read_system_*ts helper functions. The timestamp must represent the time at which the SPI slave device has processed the word, i.e. the "pre" timestamp should be taken before transmitting the "pre" word, and the "post" timestamp after receiving transmit confirmation from the controller for the "post" word.

transfer_list transfers are sequenced through **spi_message.transfers**

Description

SPI transfers always write the same number of bytes as they read. Protocol drivers should always provide **rx_buf** and/or **tx_buf**. In some cases, they may also want to provide DMA addresses for the data being transferred; that may reduce overhead, when the underlying driver uses dma.

If the transmit buffer is null, zeroes will be shifted out while filling **rx_buf**. If the receive buffer is null, the data shifted in will be discarded. Only "len" bytes shift

out (or in). It's an error to try to shift out a partial word. (For example, by shifting out three bytes with word size of sixteen or twenty bits; the former uses two bytes per word, the latter uses four bytes.)

In-memory data values are always in native CPU byte order, translated from the wire byte order (big-endian except with SPI_LSB_FIRST). So for example when bits_per_word is sixteen, buffers are 2N bytes long (**len** = 2N) and hold N sixteen bit words in CPU byte order.

When the word size of the SPI transfer is not a power-of-two multiple of eight bits, those in-memory words include extra bits. In-memory words are always seen by protocol drivers as right-justified, so the undefined (rx) or unused (tx) bits are always the most significant bits.

All SPI transfers start with the relevant chipselect active. Normally it stays selected until after the last transfer in a message. Drivers can affect the chipselect signal using cs_change.

(i) If the transfer isn't the last one in the message, this flag is used to make the chipselect briefly go inactive in the middle of the message. Toggling chipselect in this way may be needed to terminate a chip command, letting a single spi_message perform all of group of chip transactions together.

(ii) When the transfer is the last one in the message, the chip may stay selected until the next transfer. On multi-device SPI busses with nothing blocking messages going to other devices, this is just a performance hint; starting a message to another device deselects this one. But in other cases, this can be used to ensure correctness. Some devices need protocol transactions to be built from a series of spi_message submissions, where the content of one message is determined by the results of previous messages and where the whole transaction ends when the chipselect goes intactive.

When SPI can transfer in 1x,2x or 4x. It can get this transfer information from device through **tx_nbits** and **rx_nbits**. In Bi-direction, these two should both be set. User can set transfer mode with SPI_NBITS_SINGLE(1x) SPI_NBITS_DUAL(2x) and SPI_NBITS_QUAD(4x) to support these three transfer.

The code that submits an spi_message (and its spi_transfers) to the lower layers is responsible for managing its memory. Zero-initialize every field you don't set up explicitly, to insulate against future API updates. After you submit a message and its transfers, ignore them until its completion callback.

struct **spi_message**
one multi-segment SPI transaction

Definition

```
struct spi_message {
  struct list_head        transfers;
  struct spi_device       *spi;
  unsigned is_dma_mapped:1;
  void (*complete)(void *context);
  void *context;
  unsigned frame_length;
  unsigned actual_length;
  int status;
```

(continues on next page)

(continued from previous page)

```
  struct list_head        queue;
  void *state;
  struct list_head        resources;
};
```

Members

transfers list of transfer segments in this transaction

spi SPI device to which the transaction is queued

is_dma_mapped if true, the caller provided both dma and cpu virtual addresses for each transfer buffer

complete called to report transaction completions

context the argument to complete() when it's called

frame_length the total number of bytes in the message

actual_length the total number of bytes that were transferred in all successful segments

status zero for success, else negative errno

queue for use by whichever driver currently owns the message

state for use by whichever driver currently owns the message

resources for resource management when the spi message is processed

Description

A **spi_message** is used to execute an atomic sequence of data transfers, each represented by a struct spi_transfer. The sequence is "atomic" in the sense that no other spi_message may use that SPI bus until that sequence completes. On some systems, many such sequences can execute as as single programmed DMA transfer. On all systems, these messages are queued, and might complete after transactions to other devices. Messages sent to a given spi_device are always executed in FIFO order.

The code that submits an spi_message (and its spi_transfers) to the lower layers is responsible for managing its memory. Zero-initialize every field you don't set up explicitly, to insulate against future API updates. After you submit a message and its transfers, ignore them until its completion callback.

void **spi_message_init_with_transfers**(struct spi_message * m, struct spi_transfer * xfers, unsigned int num_xfers)

Initialize spi_message and append transfers

Parameters

struct spi_message * m spi_message to be initialized

struct spi_transfer * xfers An array of spi transfers

unsigned int num_xfers Number of items in the xfer array

Description

This function initializes the given spi_message and adds each spi_transfer in the given array to the message.

bool **spi_is_bpw_supported**(struct spi_device * spi, u32 bpw)
Check if bits per word is supported

Parameters

struct spi_device * spi SPI device

u32 bpw Bits per word

Description

This function checks to see if the SPI controller supports **bpw**.

Return

True if **bpw** is supported, false otherwise.

struct **spi_replaced_transfers**
structure describing the spi_transfer replacements that have occurred so that they can get reverted

Definition

```
struct spi_replaced_transfers {
  spi_replaced_release_t release;
  void *extradata;
  struct list_head replaced_transfers;
  struct list_head *replaced_after;
  size_t inserted;
  struct spi_transfer inserted_transfers[];
};
```

Members

release some extra release code to get executed prior to relasing this structure

extradata pointer to some extra data if requested or NULL

replaced_transfers transfers that have been replaced and which need to get restored

replaced_after the transfer after which the **replaced_transfers** are to get re-inserted

inserted number of transfers inserted

inserted_transfers array of spi_transfers of array-size **inserted**, that have been replacing replaced_transfers

note

that **extradata** will point to **inserted_transfers**[**inserted**] if some extra allocation is requested, so alignment will be the same as for spi_transfers

int **spi_sync_transfer**(struct spi_device * spi, struct spi_transfer * xfers, unsigned int num_xfers)
synchronous SPI data transfer

Parameters

struct spi_device * spi device with which data will be exchanged

struct spi_transfer * xfers An array of spi_transfers

unsigned int num_xfers Number of items in the xfer array

Context

can sleep

Description

Does a synchronous SPI data transfer of the given spi_transfer array.

For more specific semantics see `spi_sync()`.

Return

Return: zero on success, else a negative error code.

int **spi_write**(struct spi_device * spi, const void * buf, size_t len)
SPI synchronous write

Parameters

struct spi_device * spi device to which data will be written

const void * buf data buffer

size_t len data buffer size

Context

can sleep

Description

This function writes the buffer **buf**. Callable only from contexts that can sleep.

Return

zero on success, else a negative error code.

int **spi_read**(struct spi_device * spi, void * buf, size_t len)
SPI synchronous read

Parameters

struct spi_device * spi device from which data will be read

void * buf data buffer

size_t len data buffer size

Context

can sleep

Description

This function reads the buffer **buf**. Callable only from contexts that can sleep.

Return

zero on success, else a negative error code.

ssize_t **spi_w8r8**(struct spi_device * spi, u8 cmd)
SPI synchronous 8 bit write followed by 8 bit read

Parameters

struct spi_device * spi device with which data will be exchanged

u8 cmd command to be written before data is read back

Context

can sleep

Description

Callable only from contexts that can sleep.

Return

the (unsigned) eight bit number returned by the device, or else a negative error code.

ssize_t **spi_w8r16**(struct spi_device * spi, u8 cmd)
SPI synchronous 8 bit write followed by 16 bit read

Parameters

struct spi_device * spi device with which data will be exchanged

u8 cmd command to be written before data is read back

Context

can sleep

Description

The number is returned in wire-order, which is at least sometimes big-endian.

Callable only from contexts that can sleep.

Return

the (unsigned) sixteen bit number returned by the device, or else a negative error code.

ssize_t **spi_w8r16be**(struct spi_device * spi, u8 cmd)
SPI synchronous 8 bit write followed by 16 bit big-endian read

Parameters

struct spi_device * spi device with which data will be exchanged

u8 cmd command to be written before data is read back

Context

can sleep

Description

This function is similar to spi_w8r16, with the exception that it will convert the read 16 bit data word from big-endian to native endianness.

Callable only from contexts that can sleep.

Return

the (unsigned) sixteen bit number returned by the device in cpu endianness, or else a negative error code.

struct **spi_board_info**
board-specific template for a SPI device

Definition

```
struct spi_board_info {
  char modalias[SPI_NAME_SIZE];
  const void      *platform_data;
  const struct property_entry *properties;
  void *controller_data;
  int irq;
  u32 max_speed_hz;
  u16 bus_num;
  u16 chip_select;
  u32 mode;
};
```

Members

modalias Initializes spi_device.modalias; identifies the driver.

platform_data Initializes spi_device.platform_data; the particular data stored there is driver-specific.

properties Additional device properties for the device.

controller_data Initializes spi_device.controller_data; some controllers need hints about hardware setup, e.g. for DMA.

irq Initializes spi_device.irq; depends on how the board is wired.

max_speed_hz Initializes spi_device.max_speed_hz; based on limits from the chip datasheet and board-specific signal quality issues.

bus_num Identifies which spi_controller parents the spi_device; unused by `spi_new_device()`, and otherwise depends on board wiring.

chip_select Initializes spi_device.chip_select; depends on how the board is wired.

mode Initializes spi_device.mode; based on the chip datasheet, board wiring (some devices support both 3WIRE and standard modes), and possibly presence of an inverter in the chipselect path.

Description

When adding new SPI devices to the device tree, these structures serve as a partial device template. They hold information which can't always be determined by drivers. Information that probe() can establish (such as the default transfer wordsize) is not included here.

These structures are used in two places. Their primary role is to be stored in tables of board-specific device descriptors, which are declared early in board initialization and then used (much later) to populate a controller's device tree after the that controller's driver initializes. A secondary (and atypical) role is as a parameter

to `spi_new_device()` call, which happens after those controller drivers are active in some dynamic board configuration models.

int **spi_register_board_info**(struct spi_board_info const * info, unsigned n)
register SPI devices for a given board

Parameters

struct spi_board_info const * info array of chip descriptors

unsigned n how many descriptors are provided

Context

can sleep

Description

Board-specific early init code calls this (probably during arch_initcall) with segments of the SPI device table. Any device nodes are created later, after the relevant parent SPI controller (bus_num) is defined. We keep this table of devices forever, so that reloading a controller driver will not make Linux forget about these hard-wired devices.

Other code can also call this, e.g. a particular add-on board might provide SPI devices through its expansion connector, so code initializing that board would naturally declare its SPI devices.

The board info passed can safely be __initdata …but be careful of any embedded pointers (platform_data, etc), they' re copied as-is. Device properties are deep-copied though.

Return

zero on success, else a negative error code.

int **__spi_register_driver**(struct module * owner, struct spi_driver * sdrv)
register a SPI driver

Parameters

struct module * owner owner module of the driver to register

struct spi_driver * sdrv the driver to register

Context

can sleep

Return

zero on success, else a negative error code.

struct spi_device * **spi_alloc_device**(struct spi_controller * ctlr)
Allocate a new SPI device

Parameters

struct spi_controller * ctlr Controller to which device is connected

Context

can sleep

Description

Allows a driver to allocate and initialize a spi_device without registering it immediately. This allows a driver to directly fill the spi_device with device parameters before calling `spi_add_device()` on it.

Caller is responsible to call `spi_add_device()` on the returned spi_device structure to add it to the SPI controller. If the caller needs to discard the spi_device without adding it, then it should call spi_dev_put() on it.

Return

a pointer to the new device, or NULL.

int **spi_add_device**(struct spi_device * spi)
Add spi_device allocated with spi_alloc_device

Parameters

struct spi_device * spi spi_device to register

Description

Companion function to spi_alloc_device. Devices allocated with spi_alloc_device can be added onto the spi bus with this function.

Return

0 on success; negative errno on failure

struct spi_device * **spi_new_device**(struct spi_controller * ctlr, struct spi_board_info * chip)
instantiate one new SPI device

Parameters

struct spi_controller * ctlr Controller to which device is connected

struct spi_board_info * chip Describes the SPI device

Context

can sleep

Description

On typical mainboards, this is purely internal; and it's not needed after board init creates the hard-wired devices. Some development platforms may not be able to use spi_register_board_info though, and this is exported so that for example a USB or parport based adapter driver could add devices (which it would learn about out-of-band).

Return

the new device, or NULL.

void **spi_unregister_device**(struct spi_device * spi)
unregister a single SPI device

Parameters

struct spi_device * spi spi_device to unregister

Description

Start making the passed SPI device vanish. Normally this would be handled by `spi_unregister_controller()`.

void **spi_finalize_current_transfer**(struct spi_controller * ctlr)
report completion of a transfer

Parameters

struct spi_controller * ctlr the controller reporting completion

Description

Called by SPI drivers using the core transfer_one_message() implementation to notify it that the current interrupt driven transfer has finished and the next one may be scheduled.

void **spi_take_timestamp_pre**(struct spi_controller * ctlr, struct spi_transfer * xfer, size_t progress, bool irqs_off)
helper for drivers to collect the beginning of the TX timestamp for the requested byte from the SPI transfer. The frequency with which this function must be called (once per word, once for the whole transfer, once per batch of words etc) is arbitrary as long as the **tx** buffer offset is greater than or equal to the requested byte at the time of the call. The timestamp is only taken once, at the first such call. It is assumed that the driver advances its **tx** buffer pointer monotonically.

Parameters

struct spi_controller * ctlr Pointer to the spi_controller structure of the driver

struct spi_transfer * xfer Pointer to the transfer being timestamped

size_t progress How many words (not bytes) have been transferred so far

bool irqs_off If true, will disable IRQs and preemption for the duration of the transfer, for less jitter in time measurement. Only compatible with PIO drivers. If true, must follow up with spi_take_timestamp_post or otherwise system will crash. WARNING: for fully predictable results, the CPU frequency must also be under control (governor).

void **spi_take_timestamp_post**(struct spi_controller * ctlr, struct spi_transfer * xfer, size_t progress, bool irqs_off)
helper for drivers to collect the end of the TX timestamp for the requested byte from the SPI transfer. Can be called with an arbitrary frequency: only the first call where **tx** exceeds or is equal to the requested word will be timestamped.

Parameters

struct spi_controller * ctlr Pointer to the spi_controller structure of the driver

struct spi_transfer * xfer Pointer to the transfer being timestamped

size_t progress How many words (not bytes) have been transferred so far

bool irqs_off If true, will re-enable IRQs and preemption for the local CPU.

struct spi_message * **spi_get_next_queued_message**(struct spi_controller * ctlr)
called by driver to check for queued messages

Parameters

struct spi_controller * ctlr the controller to check for queued messages

Description

If there are more messages in the queue, the next message is returned from this call.

Return

the next message in the queue, else NULL if the queue is empty.

void **spi_finalize_current_message**(struct spi_controller * ctlr)
the current message is complete

Parameters

struct spi_controller * ctlr the controller to return the message to

Description

Called by the driver to notify the core that the message in the front of the queue is complete and can be removed from the queue.

int **spi_slave_abort**(struct spi_device * spi)
abort the ongoing transfer request on an SPI slave controller

Parameters

struct spi_device * spi device used for the current transfer

struct spi_controller * **__spi_alloc_controller**(struct device * dev, unsigned int size, bool slave)
allocate an SPI master or slave controller

Parameters

struct device * dev the controller, possibly using the platform_bus

unsigned int size how much zeroed driver-private data to allocate; the pointer to this memory is in the driver_data field of the returned device, accessible with spi_controller_get_devdata(); the memory is cacheline aligned; drivers granting DMA access to portions of their private data need to round up **size** using ALIGN(size, dma_get_cache_alignment()).

bool slave flag indicating whether to allocate an SPI master (false) or SPI slave (true) controller

Context

can sleep

Description

This call is used only by SPI controller drivers, which are the only ones directly touching chip registers. It's how they allocate an spi_controller structure, prior to calling `spi_register_controller()`.

This must be called from context that can sleep.

The caller is responsible for assigning the bus number and initializing the controller's methods before calling `spi_register_controller()`; and (after errors adding the device) calling spi_controller_put() to prevent a memory leak.

Return

the SPI controller structure on success, else NULL.

int **spi_register_controller**(struct spi_controller * ctlr)
register SPI master or slave controller

Parameters

struct spi_controller * ctlr initialized master, originally from spi_alloc_master() or spi_alloc_slave()

Context

can sleep

Description

SPI controllers connect to their drivers using some non-SPI bus, such as the platform bus. The final stage of probe() in that code includes calling `spi_register_controller()` to hook up to this SPI bus glue.

SPI controllers use board specific (often SOC specific) bus numbers, and board-specific addressing for SPI devices combines those numbers with chip select numbers. Since SPI does not directly support dynamic device identification, boards need configuration tables telling which chip is at which address.

This must be called from context that can sleep. It returns zero on success, else a negative error code (dropping the controller's refcount). After a successful return, the caller is responsible for calling `spi_unregister_controller()`.

Return

zero on success, else a negative error code.

int **devm_spi_register_controller**(struct device * dev, struct spi_controller * ctlr)
register managed SPI master or slave controller

Parameters

struct device * dev device managing SPI controller

struct spi_controller * ctlr initialized controller, originally from spi_alloc_master() or spi_alloc_slave()

Context

can sleep

Description

Register a SPI device as with `spi_register_controller()` which will automatically be unregistered and freed.

Return

zero on success, else a negative error code.

void **spi_unregister_controller**(struct spi_controller * ctlr)
unregister SPI master or slave controller

Parameters

struct spi_controller * ctlr the controller being unregistered

Context

can sleep

Description

This call is used only by SPI controller drivers, which are the only ones directly touching chip registers.

This must be called from context that can sleep.

Note that this function also drops a reference to the controller.

struct spi_controller * **spi_busnum_to_master**(u16 bus_num)
look up master associated with bus_num

Parameters

u16 bus_num the master's bus number

Context

can sleep

Description

This call may be used with devices that are registered after arch init time. It returns a refcounted pointer to the relevant spi_controller (which the caller must release), or NULL if there is no such master registered.

Return

the SPI master structure on success, else NULL.

void * **spi_res_alloc**(struct spi_device * spi, spi_res_release_t release, size_t size, gfp_t gfp)
allocate a spi resource that is life-cycle managed during the processing of a spi_message while using spi_transfer_one

Parameters

struct spi_device * spi the spi device for which we allocate memory

spi_res_release_t release the release code to execute for this resource

size_t size size to alloc and return

gfp_t gfp GFP allocation flags

Return

the pointer to the allocated data

Description

This may get enhanced in the future to allocate from a memory pool of the **spi_device** or **spi_controller** to avoid repeated allocations.

void **spi_res_free**(void * res)
free an spi resource

Parameters

void * res pointer to the custom data of a resource

void **spi_res_add**(struct spi_message * message, void * res)
add a spi_res to the spi_message

Parameters

struct spi_message * message the spi message

void * res the spi_resource

void **spi_res_release**(struct spi_controller * ctlr, struct spi_message * message)
release all spi resources for this message

Parameters

struct spi_controller * ctlr the **spi_controller**

struct spi_message * message the **spi_message**

struct spi_replaced_transfers * **spi_replace_transfers**(struct spi_message * msg, struct spi_transfer * xfer_first, size_t remove, size_t insert, spi_replaced_release_t release, size_t extradatasize, gfp_t gfp)
replace transfers with several transfers and register change with spi_message.resources

Parameters

struct spi_message * msg the spi_message we work upon

struct spi_transfer * xfer_first the first spi_transfer we want to replace

size_t remove number of transfers to remove

size_t insert the number of transfers we want to insert instead

spi_replaced_release_t release extra release code necessary in some circumstances

size_t extradatasize extra data to allocate (with alignment guarantees of struct **spi_transfer**)

gfp_t gfp gfp flags

Return

pointer to spi_replaced_transfers, PTR_ERR(…) in case of errors.

int **spi_split_transfers_maxsize**(struct spi_controller * ctlr, struct spi_message * msg, size_t maxsize, gfp_t gfp)
split spi transfers into multiple transfers when an individual transfer exceeds a certain size

Parameters

struct spi_controller * ctlr the **spi_controller** for this transfer

struct spi_message * msg the **spi_message** to transform

size_t maxsize the maximum when to apply this

gfp_t gfp GFP allocation flags

Return

status of transformation

int **spi_setup**(struct spi_device * spi)
setup SPI mode and clock rate

Parameters

struct spi_device * spi the device whose settings are being modified

Context

can sleep, and no requests are queued to the device

Description

SPI protocol drivers may need to update the transfer mode if the device doesn't work with its default. They may likewise need to update clock rates or word sizes from initial values. This function changes those settings, and must be called from a context that can sleep. Except for SPI_CS_HIGH, which takes effect immediately, the changes take effect the next time the device is selected and data is transferred to or from it. When this function returns, the spi device is deselected.

Note that this call will fail if the protocol driver specifies an option that the underlying controller or its driver does not support. For example, not all hardware supports wire transfers using nine bit words, LSB-first wire encoding, or active-high chipselects.

Return

zero on success, else a negative error code.

int **spi_set_cs_timing**(struct spi_device * spi, struct spi_delay * setup, struct spi_delay * hold, struct spi_delay * inactive)
configure CS setup, hold, and inactive delays

Parameters

struct spi_device * spi the device that requires specific CS timing configuration

struct spi_delay * setup CS setup time specified via **spi_delay**

struct spi_delay * hold CS hold time specified via **spi_delay**

struct spi_delay * inactive CS inactive delay between transfers specified via **spi_delay**

Return

zero on success, else a negative error code.

int **spi_async**(struct spi_device * spi, struct spi_message * message)
asynchronous SPI transfer

Parameters

struct spi_device * spi device with which data will be exchanged

struct spi_message * message describes the data transfers, including completion callback

Context

any (irqs may be blocked, etc)

Description

This call may be used in_irq and other contexts which can't sleep, as well as from task contexts which can sleep.

The completion callback is invoked in a context which can't sleep. Before that invocation, the value of message->status is undefined. When the callback is issued, message->status holds either zero (to indicate complete success) or a negative error code. After that callback returns, the driver which issued the transfer request may deallocate the associated memory; it's no longer in use by any SPI core or controller driver code.

Note that although all messages to a spi_device are handled in FIFO order, messages may go to different devices in other orders. Some device might be higher priority, or have various "hard" access time requirements, for example.

On detection of any fault during the transfer, processing of the entire message is aborted, and the device is deselected. Until returning from the associated message completion callback, no other spi_message queued to that device will be processed. (This rule applies equally to all the synchronous transfer calls, which are wrappers around this core asynchronous primitive.)

Return

zero on success, else a negative error code.

int **spi_async_locked**(struct spi_device * spi, struct spi_message * message)
version of spi_async with exclusive bus usage

Parameters

struct spi_device * spi device with which data will be exchanged

struct spi_message * message describes the data transfers, including completion callback

Context

any (irqs may be blocked, etc)

Description

This call may be used in_irq and other contexts which can't sleep, as well as from task contexts which can sleep.

The completion callback is invoked in a context which can't sleep. Before that invocation, the value of message->status is undefined. When the callback is issued, message->status holds either zero (to indicate complete success) or a negative error code. After that callback returns, the driver which issued the transfer request may deallocate the associated memory; it's no longer in use by any SPI core or controller driver code.

Note that although all messages to a spi_device are handled in FIFO order, messages may go to different devices in other orders. Some device might be higher priority, or have various "hard" access time requirements, for example.

On detection of any fault during the transfer, processing of the entire message is aborted, and the device is deselected. Until returning from the associated message completion callback, no other spi_message queued to that device will be processed. (This rule applies equally to all the synchronous transfer calls, which are wrappers around this core asynchronous primitive.)

Return

zero on success, else a negative error code.

int **spi_sync**(struct spi_device * spi, struct spi_message * message)
    blocking/synchronous SPI data transfers

Parameters

struct spi_device * spi device with which data will be exchanged

struct spi_message * message describes the data transfers

Context

can sleep

Description

This call may only be used from a context that may sleep. The sleep is non-interruptible, and has no timeout. Low-overhead controller drivers may DMA directly into and out of the message buffers.

Note that the SPI device's chip select is active during the message, and then is normally disabled between messages. Drivers for some frequently-used devices may want to minimize costs of selecting a chip, by leaving it selected in anticipation that the next message will go to the same chip. (That may increase power usage.)

Also, the caller is guaranteeing that the memory associated with the message will not be freed before this call returns.

Return

zero on success, else a negative error code.

int **spi_sync_locked**(struct spi_device * spi, struct spi_message * message)
    version of spi_sync with exclusive bus usage

Parameters

struct spi_device * spi device with which data will be exchanged

struct spi_message * message describes the data transfers

Context

can sleep

Description

This call may only be used from a context that may sleep. The sleep is non-interruptible, and has no timeout. Low-overhead controller drivers may DMA directly into and out of the message buffers.

This call should be used by drivers that require exclusive access to the SPI bus. It has to be preceded by a spi_bus_lock call. The SPI bus must be released by a spi_bus_unlock call when the exclusive access is over.

Return

zero on success, else a negative error code.

int **spi_bus_lock**(struct spi_controller * ctlr)
obtain a lock for exclusive SPI bus usage

Parameters

struct spi_controller * ctlr SPI bus master that should be locked for exclusive bus access

Context

can sleep

Description

This call may only be used from a context that may sleep. The sleep is non-interruptible, and has no timeout.

This call should be used by drivers that require exclusive access to the SPI bus. The SPI bus must be released by a spi_bus_unlock call when the exclusive access is over. Data transfer must be done by spi_sync_locked and spi_async_locked calls when the SPI bus lock is held.

Return

always zero.

int **spi_bus_unlock**(struct spi_controller * ctlr)
release the lock for exclusive SPI bus usage

Parameters

struct spi_controller * ctlr SPI bus master that was locked for exclusive bus access

Context

can sleep

Description

This call may only be used from a context that may sleep. The sleep is non-interruptible, and has no timeout.

This call releases an SPI bus lock previously obtained by an spi_bus_lock call.

Return

always zero.

int **spi_write_then_read**(struct spi_device * spi, const void * txbuf, unsigned n_tx, void * rxbuf, unsigned n_rx)

SPI synchronous write followed by read

Parameters

struct spi_device * spi device with which data will be exchanged

const void * txbuf data to be written (need not be dma-safe)

unsigned n_tx size of txbuf, in bytes

void * rxbuf buffer into which data will be read (need not be dma-safe)

unsigned n_rx size of rxbuf, in bytes

Context

can sleep

Description

This performs a half duplex MicroWire style transaction with the device, sending txbuf and then reading rxbuf. The return value is zero for success, else a negative errno status code. This call may only be used from a context that may sleep.

Parameters to this routine are always copied using a small buffer. Performance-sensitive or bulk transfer code should instead use spi_{async,sync}() calls with dma-safe buffers.

Return

zero on success, else a negative error code.

CHAPTER

TWENTYFOUR

I²C AND SMBUS SUBSYSTEM

I²C (or without fancy typography, "I2C") is an acronym for the "Inter-IC" bus, a simple bus protocol which is widely used where low data rate communications suffice. Since it's also a licensed trademark, some vendors use another name (such as "Two-Wire Interface", TWI) for the same bus. I2C only needs two signals (SCL for clock, SDA for data), conserving board real estate and minimizing signal quality issues. Most I2C devices use seven bit addresses, and bus speeds of up to 400 kHz; there's a high speed extension (3.4 MHz) that's not yet found wide use. I2C is a multi-master bus; open drain signaling is used to arbitrate between masters, as well as to handshake and to synchronize clocks from slower clients.

The Linux I2C programming interfaces support the master side of bus interactions and the slave side. The programming interface is structured around two kinds of driver, and two kinds of device. An I2C "Adapter Driver" abstracts the controller hardware; it binds to a physical device (perhaps a PCI device or platform_device) and exposes a `struct i2c_adapter` representing each I2C bus segment it manages. On each I2C bus segment will be I2C devices represented by a `struct i2c_client`. Those devices will be bound to a `struct i2c_driver`, which should follow the standard Linux driver model. There are functions to perform various I2C protocol operations; at this writing all such functions are usable only from task context.

The System Management Bus (SMBus) is a sibling protocol. Most SMBus systems are also I2C conformant. The electrical constraints are tighter for SMBus, and it standardizes particular protocol messages and idioms. Controllers that support I2C can also support most SMBus operations, but SMBus controllers don't support all the protocol options that an I2C controller will. There are functions to perform various SMBus protocol operations, either using I2C primitives or by issuing SMBus commands to i2c_adapter devices which don't support those I2C operations.

int **i2c_master_recv**(const struct i2c_client * client, char * buf, int count)
issue a single I2C message in master receive mode

Parameters

const struct i2c_client * client Handle to slave device

char * buf Where to store data read from slave

int count How many bytes to read, must be less than 64k since msg.len is u16

Description

Returns negative errno, or else the number of bytes read.

int **i2c_master_recv_dmasafe**(const struct i2c_client * client, char * buf, int count)
issue a single I2C message in master receive mode using a DMA safe buffer

Parameters

const struct i2c_client * client Handle to slave device

char * buf Where to store data read from slave, must be safe to use with DMA

int count How many bytes to read, must be less than 64k since msg.len is u16

Description

Returns negative errno, or else the number of bytes read.

int **i2c_master_send**(const struct i2c_client * client, const char * buf, int count)
issue a single I2C message in master transmit mode

Parameters

const struct i2c_client * client Handle to slave device

const char * buf Data that will be written to the slave

int count How many bytes to write, must be less than 64k since msg.len is u16

Description

Returns negative errno, or else the number of bytes written.

int **i2c_master_send_dmasafe**(const struct i2c_client * client, const char * buf, int count)
issue a single I2C message in master transmit mode using a DMA safe buffer

Parameters

const struct i2c_client * client Handle to slave device

const char * buf Data that will be written to the slave, must be safe to use with DMA

int count How many bytes to write, must be less than 64k since msg.len is u16

Description

Returns negative errno, or else the number of bytes written.

struct **i2c_device_identity**
i2c client device identification

Definition

```
struct i2c_device_identity {
  u16 manufacturer_id;
#define I2C_DEVICE_ID_NXP_SEMICONDUCTORS                0;

  u16 part_id;
  u8 die_revision;
};
```

Members

manufacturer_id 0 - 4095, database maintained by NXP

part_id 0 - 511, according to manufacturer

die_revision 0 - 7, according to manufacturer

struct **i2c_driver**
    represent an I2C device driver

Definition

```
struct i2c_driver {
  unsigned int class;
  int (*probe)(struct i2c_client *client, const struct i2c_device_id *id);
  int (*remove)(struct i2c_client *client);
  int (*probe_new)(struct i2c_client *client);
  void (*shutdown)(struct i2c_client *client);
  void (*alert)(struct i2c_client *client, enum i2c_alert_protocol␣
↪protocol, unsigned int data);
  int (*command)(struct i2c_client *client, unsigned int cmd, void *arg);
  struct device_driver driver;
  const struct i2c_device_id *id_table;
  int (*detect)(struct i2c_client *client, struct i2c_board_info *info);
  const unsigned short *address_list;
  struct list_head clients;
  bool disable_i2c_core_irq_mapping;
};
```

Members

class What kind of i2c device we instantiate (for detect)

probe Callback for device binding - soon to be deprecated

remove Callback for device unbinding

probe_new New callback for device binding

shutdown Callback for device shutdown

alert Alert callback, for example for the SMBus alert protocol

command Callback for bus-wide signaling (optional)

driver Device driver model driver

id_table List of I2C devices supported by this driver

detect Callback for device detection

address_list The I2C addresses to probe (for detect)

clients List of detected clients we created (for i2c-core use only)

disable_i2c_core_irq_mapping Tell the i2c-core to not do irq-mapping

Description

The driver.owner field should be set to the module owner of this driver. The driver.name field should be set to the name of this driver.

For automatic device detection, both **detect** and **address_list** must be defined. **class** should also be set, otherwise only devices forced with module parameters will be created. The detect function must fill at least the name field of the i2c_board_info structure it is handed upon successful detection, and possibly also the flags field.

If **detect** is missing, the driver will still work fine for enumerated devices. Detected devices simply won't be supported. This is expected for the many I2C/SMBus devices which can't be detected reliably, and the ones which can always be enumerated in practice.

The i2c_client structure which is handed to the **detect** callback is not a real i2c_client. It is initialized just enough so that you can call i2c_smbus_read_byte_data and friends on it. Don't do anything else with it. In particular, calling dev_dbg and friends on it is not allowed.

struct **i2c_client**
represent an I2C slave device

Definition

```
struct i2c_client {
  unsigned short flags;
#define I2C_CLIENT_PEC          0x04    ;
#define I2C_CLIENT_TEN          0x10    ;
#define I2C_CLIENT_SLAVE        0x20    ;
#define I2C_CLIENT_HOST_NOTIFY  0x40    ;
#define I2C_CLIENT_WAKE         0x80    ;
#define I2C_CLIENT_SCCB         0x9000  ;
  unsigned short addr;
  char name[I2C_NAME_SIZE];
  struct i2c_adapter *adapter;
  struct device dev;
  int init_irq;
  int irq;
  struct list_head detected;
#if IS_ENABLED(CONFIG_I2C_SLAVE);
  i2c_slave_cb_t slave_cb;
#endif;
};
```

Members

flags see I2C_CLIENT_* for possible flags

addr Address used on the I2C bus connected to the parent adapter.

name Indicates the type of the device, usually a chip name that's generic enough to hide second-sourcing and compatible revisions.

adapter manages the bus segment hosting this I2C device

dev Driver model device node for the slave.

init_irq IRQ that was set at initialization

irq indicates the IRQ generated by this device (if any)

detected member of an i2c_driver.clients list or i2c-core's userspace_devices list

slave_cb Callback when I2C slave mode of an adapter is used. The adapter calls it to pass on slave events to the slave driver.

Description

An i2c_client identifies a single device (i.e. chip) connected to an i2c bus. The behaviour exposed to Linux is defined by the driver managing the device.

struct **i2c_board_info**
template for device creation

Definition

```
struct i2c_board_info {
  char type[I2C_NAME_SIZE];
  unsigned short  flags;
  unsigned short  addr;
  const char      *dev_name;
  void *platform_data;
  struct device_node *of_node;
  struct fwnode_handle *fwnode;
  const struct property_entry *properties;
  const struct resource *resources;
  unsigned int    num_resources;
  int irq;
};
```

Members

type chip type, to initialize i2c_client.name

flags to initialize i2c_client.flags

addr stored in i2c_client.addr

dev_name Overrides the default <busnr>-<addr> dev_name if set

platform_data stored in i2c_client.dev.platform_data

of_node pointer to OpenFirmware device node

fwnode device node supplied by the platform firmware

properties additional device properties for the device

resources resources associated with the device

num_resources number of resources in the **resources** array

irq stored in i2c_client.irq

Description

I2C doesn't actually support hardware probing, although controllers and devices may be able to use I2C_SMBUS_QUICK to tell whether or not there's a device at a given address. Drivers commonly need more information than that, such as chip type, configuration, associated IRQ, and so on.

i2c_board_info is used to build tables of information listing I2C devices that are present. This information is used to grow the driver model tree. For mainboards this is done statically using `i2c_register_board_info()`; bus numbers identify adapters that aren't yet available. For add-on boards, `i2c_new_client_device()` does this dynamically with the adapter already known.

I2C_BOARD_INFO(dev_type, dev_addr)
macro used to list an i2c device and its address

Parameters

dev_type identifies the device type

dev_addr the device's address on the bus.

Description

This macro initializes essential fields of a struct i2c_board_info, declaring what has been provided on a particular board. Optional fields (such as associated irq, or device-specific platform_data) are provided using conventional syntax.

struct **i2c_algorithm**
represent I2C transfer method

Definition

```
struct i2c_algorithm {
  int (*master_xfer)(struct i2c_adapter *adap, struct i2c_msg *msgs, int␣
↪num);
  int (*master_xfer_atomic)(struct i2c_adapter *adap, struct i2c_msg *msgs,
↪ int num);
  int (*smbus_xfer)(struct i2c_adapter *adap, u16 addr,unsigned short␣
↪flags, char read_write, u8 command, int size, union i2c_smbus_data␣
↪*data);
  int (*smbus_xfer_atomic)(struct i2c_adapter *adap, u16 addr,unsigned␣
↪short flags, char read_write, u8 command, int size, union i2c_smbus_data␣
↪*data);
  u32 (*functionality)(struct i2c_adapter *adap);
#if IS_ENABLED(CONFIG_I2C_SLAVE);
  int (*reg_slave)(struct i2c_client *client);
  int (*unreg_slave)(struct i2c_client *client);
#endif;
};
```

Members

master_xfer Issue a set of i2c transactions to the given I2C adapter defined by the msgs array, with num messages available to transfer via the adapter specified by adap.

master_xfer_atomic same as **master_xfer**. Yet, only using atomic context so e.g. PMICs can be accessed very late before shutdown. Optional.

smbus_xfer Issue smbus transactions to the given I2C adapter. If this is not present, then the bus layer will try and convert the SMBus calls into I2C transfers instead.

smbus_xfer_atomic same as **smbus_xfer**. Yet, only using atomic context so e.g. PMICs can be accessed very late before shutdown. Optional.

functionality Return the flags that this algorithm/adapter pair supports from the I2C_FUNC_* flags.

reg_slave Register given client to I2C slave mode of this adapter

unreg_slave Unregister given client from I2C slave mode of this adapter

Description

The following structs are for those who like to implement new bus drivers: i2c_algorithm is the interface to a class of hardware solutions which can be addressed using the same bus algorithms - i.e. bit-banging or the PCF8584 to name two of the most common.

The return codes from the master_xfer{_atomic} fields should indicate the type of error code that occurred during the transfer, as documented in the Kernel Documentation file Documentation/i2c/fault-codes.rst.

struct **i2c_lock_operations**
represent I2C locking operations

Definition

```
struct i2c_lock_operations {
  void (*lock_bus)(struct i2c_adapter *adapter, unsigned int flags);
  int (*trylock_bus)(struct i2c_adapter *adapter, unsigned int flags);
  void (*unlock_bus)(struct i2c_adapter *adapter, unsigned int flags);
};
```

Members

lock_bus Get exclusive access to an I2C bus segment

trylock_bus Try to get exclusive access to an I2C bus segment

unlock_bus Release exclusive access to an I2C bus segment

Description

The main operations are wrapped by i2c_lock_bus and i2c_unlock_bus.

struct **i2c_timings**
I2C timing information

Definition

```
struct i2c_timings {
  u32 bus_freq_hz;
  u32 scl_rise_ns;
  u32 scl_fall_ns;
```

(continues on next page)

(continued from previous page)

```
  u32 scl_int_delay_ns;
  u32 sda_fall_ns;
  u32 sda_hold_ns;
  u32 digital_filter_width_ns;
  u32 analog_filter_cutoff_freq_hz;
};
```

Members

bus_freq_hz the bus frequency in Hz

scl_rise_ns time SCL signal takes to rise in ns; t(r) in the I2C specification

scl_fall_ns time SCL signal takes to fall in ns; t(f) in the I2C specification

scl_int_delay_ns time IP core additionally needs to setup SCL in ns

sda_fall_ns time SDA signal takes to fall in ns; t(f) in the I2C specification

sda_hold_ns time IP core additionally needs to hold SDA in ns

digital_filter_width_ns width in ns of spikes on i2c lines that the IP core digital filter can filter out

analog_filter_cutoff_freq_hz threshold frequency for the low pass IP core analog filter

struct **i2c_bus_recovery_info**
I2C bus recovery information

Definition

```
struct i2c_bus_recovery_info {
  int (*recover_bus)(struct i2c_adapter *adap);
  int (*get_scl)(struct i2c_adapter *adap);
  void (*set_scl)(struct i2c_adapter *adap, int val);
  int (*get_sda)(struct i2c_adapter *adap);
  void (*set_sda)(struct i2c_adapter *adap, int val);
  int (*get_bus_free)(struct i2c_adapter *adap);
  void (*prepare_recovery)(struct i2c_adapter *adap);
  void (*unprepare_recovery)(struct i2c_adapter *adap);
  struct gpio_desc *scl_gpiod;
  struct gpio_desc *sda_gpiod;
};
```

Members

recover_bus Recover routine. Either pass driver's recover_bus() routine, or i2c_generic_scl_recovery().

get_scl This gets current value of SCL line. Mandatory for generic SCL recovery. Populated internally for generic GPIO recovery.

set_scl This sets/clears the SCL line. Mandatory for generic SCL recovery. Populated internally for generic GPIO recovery.

get_sda This gets current value of SDA line. This or set_sda() is mandatory for generic SCL recovery. Populated internally, if sda_gpio is a valid GPIO, for generic GPIO recovery.

set_sda This sets/clears the SDA line. This or get_sda() is mandatory for generic SCL recovery. Populated internally, if sda_gpio is a valid GPIO, for generic GPIO recovery.

get_bus_free Returns the bus free state as seen from the IP core in case it has a more complex internal logic than just reading SDA. Optional.

prepare_recovery This will be called before starting recovery. Platform may configure padmux here for SDA/SCL line or something else they want.

unprepare_recovery This will be called after completing recovery. Platform may configure padmux here for SDA/SCL line or something else they want.

scl_gpiod gpiod of the SCL line. Only required for GPIO recovery.

sda_gpiod gpiod of the SDA line. Only required for GPIO recovery.

struct **i2c_adapter_quirks**
describe flaws of an i2c adapter

Definition

```
struct i2c_adapter_quirks {
  u64 flags;
  int max_num_msgs;
  u16 max_write_len;
  u16 max_read_len;
  u16 max_comb_1st_msg_len;
  u16 max_comb_2nd_msg_len;
};
```

Members

flags see I2C_AQ_* for possible flags and read below

max_num_msgs maximum number of messages per transfer

max_write_len maximum length of a write message

max_read_len maximum length of a read message

max_comb_1st_msg_len maximum length of the first msg in a combined message

max_comb_2nd_msg_len maximum length of the second msg in a combined message

Description

Note about combined messages: Some I2C controllers can only send one message per transfer, plus something called combined message or write-then-read. This is (usually) a small write message followed by a read message and barely enough to access register based devices like EEPROMs. There is a flag to support this mode. It implies max_num_msg = 2 and does the length checks with max_comb_*_len because combined message mode usually has its own limitations. Because of HW implementations, some controllers can actually do write-then-anything or other variants. To support that, write-then-read has been broken out into smaller bits like write-first and read-second which can be combined as needed.

void **i2c_lock_bus**(struct i2c_adapter * adapter, unsigned int flags)
Get exclusive access to an I2C bus segment

Parameters

struct i2c_adapter * adapter Target I2C bus segment

unsigned int flags I2C_LOCK_ROOT_ADAPTER locks the root i2c adapter, I2C_LOCK_SEGMENT locks only this branch in the adapter tree

int **i2c_trylock_bus**(struct i2c_adapter * adapter, unsigned int flags)
Try to get exclusive access to an I2C bus segment

Parameters

struct i2c_adapter * adapter Target I2C bus segment

unsigned int flags I2C_LOCK_ROOT_ADAPTER tries to locks the root i2c adapter, I2C_LOCK_SEGMENT tries to lock only this branch in the adapter tree

Return

true if the I2C bus segment is locked, false otherwise

void **i2c_unlock_bus**(struct i2c_adapter * adapter, unsigned int flags)
Release exclusive access to an I2C bus segment

Parameters

struct i2c_adapter * adapter Target I2C bus segment

unsigned int flags I2C_LOCK_ROOT_ADAPTER unlocks the root i2c adapter, I2C_LOCK_SEGMENT unlocks only this branch in the adapter tree

void **i2c_mark_adapter_suspended**(struct i2c_adapter * adap)
Report suspended state of the adapter to the core

Parameters

struct i2c_adapter * adap Adapter to mark as suspended

Description

When using this helper to mark an adapter as suspended, the core will reject further transfers to this adapter. The usage of this helper is optional but recommended for devices having distinct handlers for system suspend and runtime suspend. More complex devices are free to implement custom solutions to reject transfers when suspended.

void **i2c_mark_adapter_resumed**(struct i2c_adapter * adap)
Report resumed state of the adapter to the core

Parameters

struct i2c_adapter * adap Adapter to mark as resumed

Description

When using this helper to mark an adapter as resumed, the core will allow further transfers to this adapter. See also further notes to **i2c_mark_adapter_suspended()**.

bool **i2c_check_quirks**(struct i2c_adapter * adap, u64 quirks)
Function for checking the quirk flags in an i2c adapter

Parameters

struct i2c_adapter * adap i2c adapter

u64 quirks quirk flags

Return

true if the adapter has all the specified quirk flags, false if not

module_i2c_driver(__i2c_driver)
Helper macro for registering a modular I2C driver

Parameters

__i2c_driver i2c_driver struct

Description

Helper macro for I2C drivers which do not do anything special in module init/exit. This eliminates a lot of boilerplate. Each module may only use this macro once, and calling it replaces `module_init()` and `module_exit()`

builtin_i2c_driver(__i2c_driver)
Helper macro for registering a builtin I2C driver

Parameters

__i2c_driver i2c_driver struct

Description

Helper macro for I2C drivers which do not do anything special in their init. This eliminates a lot of boilerplate. Each driver may only use this macro once, and calling it replaces device_initcall().

int **i2c_register_board_info**(int busnum, struct i2c_board_info const * info, unsigned len)
statically declare I2C devices

Parameters

int busnum identifies the bus to which these devices belong

struct i2c_board_info const * info vector of i2c device descriptors

unsigned len how many descriptors in the vector; may be zero to reserve the specified bus number.

Description

Systems using the Linux I2C driver stack can declare tables of board info while they initialize. This should be done in board-specific init code near arch_initcall() time, or equivalent, before any I2C adapter driver is registered. For example, mainboard init code could define several devices, as could the init code for each daughtercard in a board stack.

The I2C devices will be created later, after the adapter for the relevant bus has been registered. After that moment, standard driver model tools are used to bind “new style” I2C drivers to the devices. The bus number for any device declared using this routine is not available for dynamic allocation.

The board info passed can safely be __initdata, but be careful of embedded pointers (for platform_data, functions, etc) since that won't be copied. Device properties are deep-copied though.

struct i2c_client * **i2c_verify_client**(struct device * dev)
return parameter as i2c_client, or NULL

Parameters

struct device * dev device, probably from some driver model iterator

Description

When traversing the driver model tree, perhaps using driver model iterators like **device_for_each_child()**, you can't assume very much about the nodes you find. Use this function to avoid oopses caused by wrongly treating some non-I2C device as an i2c_client.

struct i2c_client * **i2c_new_client_device**(struct i2c_adapter * adap, struct i2c_board_info const * info)
instantiate an i2c device

Parameters

struct i2c_adapter * adap the adapter managing the device

struct i2c_board_info const * info describes one I2C device; bus_num is ignored

Context

can sleep

Description

Create an i2c device. Binding is handled through driver model probe()/remove() methods. A driver may be bound to this device when we return from this function, or any later moment (e.g. maybe hotplugging will load the driver module). This call is not appropriate for use by mainboard initialization logic, which usually runs during an arch_initcall() long before any i2c_adapter could exist.

This returns the new i2c client, which may be saved for later use with `i2c_unregister_device()`; or an ERR_PTR to describe the error.

void **i2c_unregister_device**(struct i2c_client * client)
reverse effect of i2c_new_*_device()

Parameters

struct i2c_client * client value returned from i2c_new_*_device()

Context

can sleep

struct i2c_client * **i2c_new_dummy_device**(struct i2c_adapter * adapter, u16 address)
return a new i2c device bound to a dummy driver

Parameters

struct i2c_adapter * adapter the adapter managing the device

u16 address seven bit address to be used

Context

can sleep

Description

This returns an I2C client bound to the “dummy” driver, intended for use with devices that consume multiple addresses. Examples of such chips include various EEPROMS (like 24c04 and 24c08 models).

These dummy devices have two main uses. First, most I2C and SMBus calls except `i2c_transfer()` need a client handle; the dummy will be that handle. And second, this prevents the specified address from being bound to a different driver.

This returns the new i2c client, which should be saved for later use with `i2c_unregister_device()`; or an ERR_PTR to describe the error.

struct i2c_client * **devm_i2c_new_dummy_device**(struct device * dev, struct i2c_adapter * adapter, u16 address)

return a new i2c device bound to a dummy driver

Parameters

struct device * dev device the managed resource is bound to

struct i2c_adapter * adapter the adapter managing the device

u16 address seven bit address to be used

Context

can sleep

Description

This is the device-managed version of **i2c_new_dummy_device**. It returns the new i2c client or an ERR_PTR in case of an error.

struct i2c_client * **i2c_new_ancillary_device**(struct i2c_client * client, const char * name, u16 default_addr)

Helper to get the instantiated secondary address and create the associated device

Parameters

struct i2c_client * client Handle to the primary client

const char * name Handle to specify which secondary address to get

u16 default_addr Used as a fallback if no secondary address was specified

Context

can sleep

Description

I2C clients can be composed of multiple I2C slaves bound together in a single component. The I2C client driver then binds to the master I2C slave and needs to create I2C dummy clients to communicate with all the other slaves.

This function creates and returns an I2C dummy client whose I2C address is retrieved from the platform firmware based on the given slave name. If no address is specified by the firmware default_addr is used.

On DT-based platforms the address is retrieved from the "reg" property entry cell whose "reg-names" value matches the slave name.

This returns the new i2c client, which should be saved for later use with `i2c_unregister_device()`; or an ERR_PTR to describe the error.

struct i2c_adapter * **i2c_verify_adapter**(struct device * dev)
return parameter as i2c_adapter or NULL

Parameters

struct device * dev device, probably from some driver model iterator

Description

When traversing the driver model tree, perhaps using driver model iterators like **device_for_each_child()**, you can't assume very much about the nodes you find. Use this function to avoid oopses caused by wrongly treating some non-I2C device as an i2c_adapter.

int **i2c_handle_smbus_host_notify**(struct i2c_adapter * adap, unsigned short addr)
Forward a Host Notify event to the correct I2C client.

Parameters

struct i2c_adapter * adap the adapter

unsigned short addr the I2C address of the notifying device

Context

can't sleep

Description

Helper function to be called from an I2C bus driver's interrupt handler. It will schedule the Host Notify IRQ.

int **i2c_add_adapter**(struct i2c_adapter * adapter)
declare i2c adapter, use dynamic bus number

Parameters

struct i2c_adapter * adapter the adapter to add

Context

can sleep

Description

This routine is used to declare an I2C adapter when its bus number doesn't matter or when its bus number is specified by an dt alias. Examples of bases when the bus number doesn't matter: I2C adapters dynamically added by USB links or PCI plugin cards.

When this returns zero, a new bus number was allocated and stored in adap->nr, and the specified adapter became available for clients. Otherwise, a negative errno value is returned.

int **i2c_add_numbered_adapter**(struct i2c_adapter * adap)
declare i2c adapter, use static bus number

Parameters

struct i2c_adapter * adap the adapter to register (with adap->nr initialized)

Context

can sleep

Description

This routine is used to declare an I2C adapter when its bus number matters. For example, use it for I2C adapters from system-on-chip CPUs, or otherwise built in to the system's mainboard, and where i2c_board_info is used to properly configure I2C devices.

If the requested bus number is set to -1, then this function will behave identically to i2c_add_adapter, and will dynamically assign a bus number.

If no devices have pre-been declared for this bus, then be sure to register the adapter before any dynamically allocated ones. Otherwise the required bus ID may not be available.

When this returns zero, the specified adapter became available for clients using the bus number provided in adap->nr. Also, the table of I2C devices pre-declared using `i2c_register_board_info()` is scanned, and the appropriate driver model device nodes are created. Otherwise, a negative errno value is returned.

void **i2c_del_adapter**(struct i2c_adapter * adap)
unregister I2C adapter

Parameters

struct i2c_adapter * adap the adapter being unregistered

Context

can sleep

Description

This unregisters an I2C adapter which was previously registered by **i2c_add_adapter** or **i2c_add_numbered_adapter**.

void **i2c_parse_fw_timings**(struct device * dev, struct i2c_timings * t,
bool use_defaults)
get I2C related timing parameters from firmware

Parameters

struct device * dev The device to scan for I2C timing properties

struct i2c_timings * t the i2c_timings struct to be filled with values

bool use_defaults bool to use sane defaults derived from the I2C specification when properties are not found, otherwise don't update

Description

Scan the device for the generic I2C properties describing timing parameters for the signal and fill the given struct with the results. If a property was not found and use_defaults was true, then maximum timings are assumed which are derived from the I2C specification. If use_defaults is not used, the results will be as before, so drivers can apply their own defaults before calling this helper. The latter is mainly intended for avoiding regressions of existing drivers which want to switch to this function. New drivers almost always should use the defaults.

void **i2c_del_driver**(struct i2c_driver * driver)
unregister I2C driver

Parameters

struct i2c_driver * driver the driver being unregistered

Context

can sleep

int **__i2c_transfer**(struct i2c_adapter * adap, struct i2c_msg * msgs, int num)
unlocked flavor of i2c_transfer

Parameters

struct i2c_adapter * adap Handle to I2C bus

struct i2c_msg * msgs One or more messages to execute before STOP is issued to terminate the operation; each message begins with a START.

int num Number of messages to be executed.

Description

Returns negative errno, else the number of messages executed.

Adapter lock must be held when calling this function. No debug logging takes place. adap->algo->master_xfer existence isn't checked.

int **i2c_transfer**(struct i2c_adapter * adap, struct i2c_msg * msgs, int num)
execute a single or combined I2C message

Parameters

struct i2c_adapter * adap Handle to I2C bus

struct i2c_msg * msgs One or more messages to execute before STOP is issued to terminate the operation; each message begins with a START.

int num Number of messages to be executed.

Description

Returns negative errno, else the number of messages executed.

Note that there is no requirement that each message be sent to the same slave address, although that is the most common model.

int **i2c_transfer_buffer_flags**(const struct i2c_client * client, char * buf, int count, u16 flags)
issue a single I2C message transferring data to/from a buffer

Parameters

const struct i2c_client * client Handle to slave device

char * buf Where the data is stored

int count How many bytes to transfer, must be less than 64k since msg.len is u16

u16 flags The flags to be used for the message, e.g. I2C_M_RD for reads

Description

Returns negative errno, or else the number of bytes transferred.

int **i2c_get_device_id**(const struct i2c_client * client, struct i2c_device_identity * id)
get manufacturer, part id and die revision of a device

Parameters

const struct i2c_client * client The device to query

struct i2c_device_identity * id The queried information

Description

Returns negative errno on error, zero on success.

u8 * **i2c_get_dma_safe_msg_buf**(struct i2c_msg * msg, unsigned int threshold)
get a DMA safe buffer for the given i2c_msg

Parameters

struct i2c_msg * msg the message to be checked

unsigned int threshold the minimum number of bytes for which using DMA makes sense. Should at least be 1.

Return

NULL if a DMA safe buffer was not obtained. Use msg->buf with PIO.
Or a valid pointer to be used with DMA. After use, release it by calling `i2c_put_dma_safe_msg_buf()`.

Description

This function must only be called from process context!

void **i2c_put_dma_safe_msg_buf**(u8 * buf, struct i2c_msg * msg, bool xferred)
release DMA safe buffer and sync with i2c_msg

Parameters

u8 * buf the buffer obtained from `i2c_get_dma_safe_msg_buf()`. May be NULL.

struct i2c_msg * msg the message which the buffer corresponds to

bool xferred bool saying if the message was transferred

s32 **i2c_smbus_read_byte**(const struct i2c_client * client)
SMBus “receive byte” protocol

Parameters

const struct i2c_client * client Handle to slave device

Description

This executes the SMBus “receive byte” protocol, returning negative errno else the byte received from the device.

s32 **i2c_smbus_write_byte**(const struct i2c_client * client, u8 value)
SMBus “send byte” protocol

Parameters

const struct i2c_client * client Handle to slave device

u8 value Byte to be sent

Description

This executes the SMBus “send byte” protocol, returning negative errno else zero on success.

s32 **i2c_smbus_read_byte_data**(const struct i2c_client * client, u8 command)
SMBus “read byte” protocol

Parameters

const struct i2c_client * client Handle to slave device

u8 command Byte interpreted by slave

Description

This executes the SMBus “read byte” protocol, returning negative errno else a data byte received from the device.

s32 **i2c_smbus_write_byte_data**(const struct i2c_client * client, u8 command, u8 value)
SMBus “write byte” protocol

Parameters

const struct i2c_client * client Handle to slave device

u8 command Byte interpreted by slave

u8 value Byte being written

Description

This executes the SMBus “write byte” protocol, returning negative errno else zero on success.

s32 **i2c_smbus_read_word_data**(const struct i2c_client * client, u8 command)
SMBus “read word” protocol

Parameters

const struct i2c_client * client Handle to slave device

u8 command Byte interpreted by slave

Description

This executes the SMBus “read word” protocol, returning negative errno else a 16-bit unsigned “word” received from the device.

s32 **i2c_smbus_write_word_data**(const struct i2c_client * client, u8 command, u16 value)
SMBus “write word” protocol

Parameters

const struct i2c_client * client Handle to slave device

u8 command Byte interpreted by slave

u16 value 16-bit “word” being written

Description

This executes the SMBus “write word” protocol, returning negative errno else zero on success.

s32 **i2c_smbus_read_block_data**(const struct i2c_client * client, u8 command, u8 * values)
SMBus “block read” protocol

Parameters

const struct i2c_client * client Handle to slave device

u8 command Byte interpreted by slave

u8 * values Byte array into which data will be read; big enough to hold the data returned by the slave. SMBus allows at most 32 bytes.

Description

This executes the SMBus “block read” protocol, returning negative errno else the number of data bytes in the slave’s response.

Note that using this function requires that the client’s adapter support the I2C_FUNC_SMBUS_READ_BLOCK_DATA functionality. Not all adapter drivers support this; its emulation through I2C messaging relies on a specific mechanism (I2C_M_RECV_LEN) which may not be implemented.

s32 **i2c_smbus_write_block_data**(const struct i2c_client * client, u8 command, u8 length, const u8 * values)
SMBus “block write” protocol

Parameters

const struct i2c_client * client Handle to slave device

u8 command Byte interpreted by slave

u8 length Size of data block; SMBus allows at most 32 bytes

const u8 * values Byte array which will be written.

Description

This executes the SMBus “block write” protocol, returning negative errno else zero on success.

s32 **i2c_smbus_xfer**(struct i2c_adapter * adapter, u16 addr, unsigned short flags, char read_write, u8 command, int protocol, union i2c_smbus_data * data)
execute SMBus protocol operations

Parameters

struct i2c_adapter * adapter Handle to I2C bus

u16 addr Address of SMBus slave on that bus

unsigned short flags I2C_CLIENT_* flags (usually zero or I2C_CLIENT_PEC)

char read_write I2C_SMBUS_READ or I2C_SMBUS_WRITE

u8 command Byte interpreted by slave, for protocols which use such bytes

int protocol SMBus protocol operation to execute, such as I2C_SMBUS_PROC_CALL

union i2c_smbus_data * data Data to be read or written

Description

This executes an SMBus protocol operation, and returns a negative errno code else zero on success.

s32 **i2c_smbus_read_i2c_block_data_or_emulated**(const struct i2c_client * client, u8 command, u8 length, u8 * values)
read block or emulate

Parameters

const struct i2c_client * client Handle to slave device

u8 command Byte interpreted by slave

u8 length Size of data block; SMBus allows at most I2C_SMBUS_BLOCK_MAX bytes

u8 * values Byte array into which data will be read; big enough to hold the data returned by the slave. SMBus allows at most I2C_SMBUS_BLOCK_MAX bytes.

Description

This executes the SMBus “block read” protocol if supported by the adapter. If block read is not supported, it emulates it using either word or byte read protocols depending on availability.

The addresses of the I2C slave device that are accessed with this function must be mapped to a linear region, so that a block read will have the same effect as a byte read. Before using this function you must double-check if the I2C slave does support exchanging a block transfer with a byte transfer.

struct i2c_client * **i2c_new_smbus_alert_device**(struct i2c_adapter * adapter, struct i2c_smbus_alert_setup * setup)
get ara client for SMBus alert support

Parameters

struct i2c_adapter * adapter the target adapter

struct i2c_smbus_alert_setup * setup setup data for the SMBus alert handler

Context

can sleep

Description

Setup handling of the SMBus alert protocol on a given I2C bus segment.

Handling can be done either through our IRQ handler, or by the adapter (from its handler, periodic polling, or whatever).

This returns the ara client, which should be saved for later use with i2c_handle_smbus_alert() and ultimately `i2c_unregister_device()`; or an ERRPTR to indicate an error.

CHAPTER

TWENTYFIVE

IPMB DRIVER FOR A SATELLITE MC

The Intelligent Platform Management Bus or IPMB, is an I2C bus that provides a standardized interconnection between different boards within a chassis. This interconnection is between the baseboard management (BMC) and chassis electronics. IPMB is also associated with the messaging protocol through the IPMB bus.

The devices using the IPMB are usually management controllers that perform management functions such as servicing the front panel interface, monitoring the baseboard, hot-swapping disk drivers in the system chassis, etc⋯

When an IPMB is implemented in the system, the BMC serves as a controller to give system software access to the IPMB. The BMC sends IPMI requests to a device (usually a Satellite Management Controller or Satellite MC) via IPMB and the device sends a response back to the BMC.

For more information on IPMB and the format of an IPMB message, refer to the IPMB and IPMI specifications.

25.1 IPMB driver for Satellite MC

ipmb-dev-int - This is the driver needed on a Satellite MC to receive IPMB messages from a BMC and send a response back. This driver works with the I2C driver and a userspace program such as OpenIPMI:

1) It is an I2C slave backend driver. So, it defines a callback function to set the Satellite MC as an I2C slave. This callback function handles the received IPMI requests.

2) It defines the read and write functions to enable a user space program (such as OpenIPMI) to communicate with the kernel.

25.2 Load the IPMB driver

The driver needs to be loaded at boot time or manually first. First, make sure you have the following in your config file: CONFIG_IPMB_DEVICE_INTERFACE=y

1) If you want the driver to be loaded at boot time:

a) Add this entry to your ACPI table, under the appropriate SMBus:

```
Device (SMB0) // Example SMBus host controller
{
Name (_HID, "<Vendor-Specific HID>") // Vendor-Specific HID
Name (_UID, 0) // Unique ID of particular host controller
:
:
  Device (IPMB)
  {
    Name (_HID, "IPMB0001") // IPMB device interface
    Name (_UID, 0) // Unique device identifier
  }
}
```

b) Example for device tree:

```
&i2c2 {
       status = "okay";

       ipmb@10 {
               compatible = "ipmb-dev";
               reg = <0x10>;
               i2c-protocol;
       };
};
```

If xmit of data to be done using raw i2c block vs smbus then “i2c-protocol” needs to be defined as above.

2) Manually from Linux:

```
modprobe ipmb-dev-int
```

25.3 Instantiate the device

After loading the driver, you can instantiate the device as described in ‘Documentation/i2c/instantiating-devices.rst’. If you have multiple BMCs, each connected to your Satellite MC via a different I2C bus, you can instantiate a device for each of those BMCs.

The name of the instantiated device contains the I2C bus number associated with it as follows:

```
BMC1 ------ IPMB/I2C bus 1 ---------|   /dev/ipmb-1
                                Satellite MC
BMC1 ------ IPMB/I2C bus 2 ---------|   /dev/ipmb-2
```

For instance, you can instantiate the ipmb-dev-int device from user space at the 7 bit address 0x10 on bus 2:

```
# echo ipmb-dev 0x1010 > /sys/bus/i2c/devices/i2c-2/new_device
```

This will create the device file /dev/ipmb-2, which can be accessed by the user space program. The device needs to be instantiated before running the user space program.

CHAPTER

TWENTYSIX

THE LINUX IPMI DRIVER

Author Corey Minyard <minyard@mvista.com> / <minyard@acm.org>

The Intelligent Platform Management Interface, or IPMI, is a standard for controlling intelligent devices that monitor a system. It provides for dynamic discovery of sensors in the system and the ability to monitor the sensors and be informed when the sensor's values change or go outside certain boundaries. It also has a standardized database for field-replaceable units (FRUs) and a watchdog timer.

To use this, you need an interface to an IPMI controller in your system (called a Baseboard Management Controller, or BMC) and management software that can use the IPMI system.

This document describes how to use the IPMI driver for Linux. If you are not familiar with IPMI itself, see the web site at http://www.intel.com/design/servers/ipmi/index.htm. IPMI is a big subject and I can't cover it all here!

26.1 Configuration

The Linux IPMI driver is modular, which means you have to pick several things to have it work right depending on your hardware. Most of these are available in the 'Character Devices' menu then the IPMI menu.

No matter what, you must pick 'IPMI top-level message handler' to use IPMI. What you do beyond that depends on your needs and hardware.

The message handler does not provide any user-level interfaces. Kernel code (like the watchdog) can still use it. If you need access from userland, you need to select 'Device interface for IPMI' if you want access through a device driver.

The driver interface depends on your hardware. If your system properly provides the SMBIOS info for IPMI, the driver will detect it and just work. If you have a board with a standard interface (These will generally be either "KCS", "SMIC", or "BT", consult your hardware manual), choose the 'IPMI SI handler' option. A driver also exists for direct I2C access to the IPMI management controller. Some boards support this, but it is unknown if it will work on every board. For this, choose 'IPMI SMBus handler', but be ready to try to do some figuring to see if it will work on your system if the SMBIOS/APCI information is wrong or not present. It is fairly safe to have both these enabled and let the drivers auto-detect what is present.

You should generally enable ACPI on your system, as systems with IPMI can have ACPI tables describing them.

If you have a standard interface and the board manufacturer has done their job correctly, the IPMI controller should be automatically detected (via ACPI or SMBIOS tables) and should just work. Sadly, many boards do not have this information. The driver attempts standard defaults, but they may not work. If you fall into this situation, you need to read the section below named 'The SI Driver' or "The SMBus Driver" on how to hand-configure your system.

IPMI defines a standard watchdog timer. You can enable this with the 'IPMI Watchdog Timer' config option. If you compile the driver into the kernel, then via a kernel command-line option you can have the watchdog timer start as soon as it initializes. It also have a lot of other options, see the 'Watchdog' section below for more details. Note that you can also have the watchdog continue to run if it is closed (by default it is disabled on close). Go into the 'Watchdog Cards' menu, enable 'Watchdog Timer Support', and enable the option 'Disable watchdog shutdown on close'.

IPMI systems can often be powered off using IPMI commands. Select 'IPMI Poweroff' to do this. The driver will auto-detect if the system can be powered off by IPMI. It is safe to enable this even if your system doesn't support this option. This works on ATCA systems, the Radisys CPI1 card, and any IPMI system that supports standard chassis management commands.

If you want the driver to put an event into the event log on a panic, enable the 'Generate a panic event to all BMCs on a panic' option. If you want the whole panic string put into the event log using OEM events, enable the 'Generate OEM events containing the panic string' option. You can also enable these dynamically by setting the module parameter named "panic_op"in the ipmi_msghandler module to "event" or "string". Setting that parameter to "none" disables this function.

26.2 Basic Design

The Linux IPMI driver is designed to be very modular and flexible, you only need to take the pieces you need and you can use it in many different ways. Because of that, it's broken into many chunks of code. These chunks (by module name) are:

ipmi_msghandler - This is the central piece of software for the IPMI system. It handles all messages, message timing, and responses. The IPMI users tie into this, and the IPMI physical interfaces (called System Management Interfaces, or SMIs) also tie in here. This provides the kernelland interface for IPMI, but does not provide an interface for use by application processes.

ipmi_devintf - This provides a userland IOCTL interface for the IPMI driver, each open file for this device ties in to the message handler as an IPMI user.

ipmi_si - A driver for various system interfaces. This supports KCS, SMIC, and BT interfaces. Unless you have an SMBus interface or your own custom interface, you probably need to use this.

ipmi_ssif - A driver for accessing BMCs on the SMBus. It uses the I2C kernel driver's SMBus interfaces to send and receive IPMI messages over the SMBus.

ipmi_powernv - A driver for access BMCs on POWERNV systems.

ipmi_watchdog - IPMI requires systems to have a very capable watchdog timer. This driver implements the standard Linux watchdog timer interface on top of the IPMI message handler.

ipmi_poweroff - Some systems support the ability to be turned off via IPMI commands.

bt-bmc - This is not part of the main driver, but instead a driver for accessing a BMC-side interface of a BT interface. It is used on BMCs running Linux to provide an interface to the host.

These are all individually selectable via configuration options.

Much documentation for the interface is in the include files. The IPMI include files are:

linux/ipmi.h - Contains the user interface and IOCTL interface for IPMI.

linux/ipmi_smi.h - Contains the interface for system management interfaces (things that interface to IPMI controllers) to use.

linux/ipmi_msgdefs.h - General definitions for base IPMI messaging.

26.3 Addressing

The IPMI addressing works much like IP addresses, you have an overlay to handle the different address types. The overlay is:

```
struct ipmi_addr
{
      int   addr_type;
      short channel;
      char  data[IPMI_MAX_ADDR_SIZE];
};
```

The addr_type determines what the address really is. The driver currently understands two different types of addresses.

"System Interface" addresses are defined as:

```
struct ipmi_system_interface_addr
{
      int   addr_type;
      short channel;
};
```

and the type is IPMI_SYSTEM_INTERFACE_ADDR_TYPE. This is used for talking straight to the BMC on the current card. The channel must be IPMI_BMC_CHANNEL.

Messages that are destined to go out on the IPMB bus use the IPMI_IPMB_ADDR_TYPE address type. The format is:

```
struct ipmi_ipmb_addr
{
      int           addr_type;
      short         channel;
      unsigned char slave_addr;
      unsigned char lun;
};
```

The “channel” here is generally zero, but some devices support more than one channel, it corresponds to the channel as defined in the IPMI spec.

26.4 Messages

Messages are defined as:

```
struct ipmi_msg
{
      unsigned char netfn;
      unsigned char lun;
      unsigned char cmd;
      unsigned char *data;
      int           data_len;
};
```

The driver takes care of adding/stripping the header information. The data portion is just the data to be send (do NOT put addressing info here) or the response. Note that the completion code of a response is the first item in “data”, it is not stripped out because that is how all the messages are defined in the spec (and thus makes counting the offsets a little easier :-).

When using the IOCTL interface from userland, you must provide a block of data for “data”, fill it, and set data_len to the length of the block of data, even when receiving messages. Otherwise the driver will have no place to put the message.

Messages coming up from the message handler in kernelland will come in as:

```
struct ipmi_recv_msg
{
      struct list_head link;

      /* The type of message as defined in the "Receive Types"
         defines above. */
      int         recv_type;

      ipmi_user_t      *user;
      struct ipmi_addr addr;
      long             msgid;
      struct ipmi_msg  msg;

      /* Call this when done with the message.  It will presumably free
         the message and do any other necessary cleanup. */
      void (*done)(struct ipmi_recv_msg *msg);

      /* Place-holder for the data, don't make any assumptions about
```

(continues on next page)

(continued from previous page)

```
        the size or existence of this, since it may change. */
     unsigned char   msg_data[IPMI_MAX_MSG_LENGTH];
};
```

You should look at the receive type and handle the message appropriately.

26.5 The Upper Layer Interface (Message Handler)

The upper layer of the interface provides the users with a consistent view of the IPMI interfaces. It allows multiple SMI interfaces to be addressed (because some boards actually have multiple BMCs on them) and the user should not have to care what type of SMI is below them.

26.5.1 Watching For Interfaces

When your code comes up, the IPMI driver may or may not have detected if IPMI devices exist. So you might have to defer your setup until the device is detected, or you might be able to do it immediately. To handle this, and to allow for discovery, you register an SMI watcher with ipmi_smi_watcher_register() to iterate over interfaces and tell you when they come and go.

26.5.2 Creating the User

To use the message handler, you must first create a user using ipmi_create_user. The interface number specifies which SMI you want to connect to, and you must supply callback functions to be called when data comes in. The callback function can run at interrupt level, so be careful using the callbacks. This also allows to you pass in a piece of data, the handler_data, that will be passed back to you on all calls.

Once you are done, call ipmi_destroy_user() to get rid of the user.

From userland, opening the device automatically creates a user, and closing the device automatically destroys the user.

26.5.3 Messaging

To send a message from kernel-land, the ipmi_request_settime() call does pretty much all message handling. Most of the parameter are self-explanatory. However, it takes a "msgid" parameter. This is NOT the sequence number of messages. It is simply a long value that is passed back when the response for the message is returned. You may use it for anything you like.

Responses come back in the function pointed to by the ipmi_recv_hndl field of the "handler" that you passed in to ipmi_create_user(). Remember again, these may be running at interrupt level. Remember to look at the receive type, too.

From userland, you fill out an ipmi_req_t structure and use the IPMICTL_SEND_COMMAND ioctl. For incoming stuff, you can use select() or poll()

to wait for messages to come in. However, you cannot use read() to get them, you must call the IPMICTL_RECEIVE_MSG with the ipmi_recv_t structure to actually get the message. Remember that you must supply a pointer to a block of data in the msg.data field, and you must fill in the msg.data_len field with the size of the data. This gives the receiver a place to actually put the message.

If the message cannot fit into the data you provide, you will get an EMSGSIZE error and the driver will leave the data in the receive queue. If you want to get it and have it truncate the message, us the IPMICTL_RECEIVE_MSG_TRUNC ioctl.

When you send a command (which is defined by the lowest-order bit of the netfn per the IPMI spec) on the IPMB bus, the driver will automatically assign the sequence number to the command and save the command. If the response is not receive in the IPMI-specified 5 seconds, it will generate a response automatically saying the command timed out. If an unsolicited response comes in (if it was after 5 seconds, for instance), that response will be ignored.

In kernelland, after you receive a message and are done with it, you MUST call ipmi_free_recv_msg() on it, or you will leak messages. Note that you should NEVER mess with the "done" field of a message, that is required to properly clean up the message.

Note that when sending, there is an ipmi_request_supply_msgs() call that lets you supply the smi and receive message. This is useful for pieces of code that need to work even if the system is out of buffers (the watchdog timer uses this, for instance). You supply your own buffer and own free routines. This is not recommended for normal use, though, since it is tricky to manage your own buffers.

26.5.4 Events and Incoming Commands

The driver takes care of polling for IPMI events and receiving commands (commands are messages that are not responses, they are commands that other things on the IPMB bus have sent you). To receive these, you must register for them, they will not automatically be sent to you.

To receive events, you must call ipmi_set_gets_events() and set the "val" to non-zero. Any events that have been received by the driver since startup will immediately be delivered to the first user that registers for events. After that, if multiple users are registered for events, they will all receive all events that come in.

For receiving commands, you have to individually register commands you want to receive. Call ipmi_register_for_cmd() and supply the netfn and command name for each command you want to receive. You also specify a bitmask of the channels you want to receive the command from (or use IPMI_CHAN_ALL for all channels if you don't care). Only one user may be registered for each netfn/cmd/channel, but different users may register for different commands, or the same command if the channel bitmasks do not overlap.

From userland, equivalent IOCTLs are provided to do these functions.

26.6 The Lower Layer (SMI) Interface

As mentioned before, multiple SMI interfaces may be registered to the message handler, each of these is assigned an interface number when they register with the message handler. They are generally assigned in the order they register, although if an SMI unregisters and then another one registers, all bets are off.

The ipmi_smi.h defines the interface for management interfaces, see that for more details.

26.7 The SI Driver

The SI driver allows KCS, BT, and SMIC interfaces to be configured in the system. It discovers interfaces through a host of different methods, depending on the system.

You can specify up to four interfaces on the module load line and control some module parameters:

```
modprobe ipmi_si.o type=<type1>,<type2>....
     ports=<port1>,<port2>... addrs=<addr1>,<addr2>...
     irqs=<irq1>,<irq2>...
     regspacings=<sp1>,<sp2>,... regsizes=<size1>,<size2>,...
     regshifts=<shift1>,<shift2>,...
     slave_addrs=<addr1>,<addr2>,...
     force_kipmid=<enable1>,<enable2>,...
     kipmid_max_busy_us=<ustime1>,<ustime2>,...
     unload_when_empty=[0|1]
     trydmi=[0|1] tryacpi=[0|1]
     tryplatform=[0|1] trypci=[0|1]
```

Each of these except try⋯items is a list, the first item for the first interface, second item for the second interface, etc.

The si_type may be either “kcs”, “smic”, or “bt”. If you leave it blank, it defaults to “kcs”.

If you specify addrs as non-zero for an interface, the driver will use the memory address given as the address of the device. This overrides si_ports.

If you specify ports as non-zero for an interface, the driver will use the I/O port given as the device address.

If you specify irqs as non-zero for an interface, the driver will attempt to use the given interrupt for the device.

The other try⋯items disable discovery by their corresponding names. These are all enabled by default, set them to zero to disable them. The tryplatform disables openfirmware.

The next three parameters have to do with register layout. The registers used by the interfaces may not appear at successive locations and they may not be in 8-bit registers. These parameters allow the layout of the data in the registers to be more precisely specified.

The regspacings parameter give the number of bytes between successive register start addresses. For instance, if the regspacing is set to 4 and the start address is 0xca2, then the address for the second register would be 0xca6. This defaults to 1.

The regsizes parameter gives the size of a register, in bytes. The data used by IPMI is 8-bits wide, but it may be inside a larger register. This parameter allows the read and write type to specified. It may be 1, 2, 4, or 8. The default is 1.

Since the register size may be larger than 32 bits, the IPMI data may not be in the lower 8 bits. The regshifts parameter give the amount to shift the data to get to the actual IPMI data.

The slave_addrs specifies the IPMI address of the local BMC. This is usually 0x20 and the driver defaults to that, but in case it's not, it can be specified when the driver starts up.

The force_ipmid parameter forcefully enables (if set to 1) or disables (if set to 0) the kernel IPMI daemon. Normally this is auto-detected by the driver, but systems with broken interrupts might need an enable, or users that don't want the daemon (don't need the performance, don't want the CPU hit) can disable it.

If unload_when_empty is set to 1, the driver will be unloaded if it doesn't find any interfaces or all the interfaces fail to work. The default is one. Setting to 0 is useful with the hotmod, but is obviously only useful for modules.

When compiled into the kernel, the parameters can be specified on the kernel command line as:

```
ipmi_si.type=<type1>,<type2>...
     ipmi_si.ports=<port1>,<port2>... ipmi_si.addrs=<addr1>,<addr2>...
     ipmi_si.irqs=<irq1>,<irq2>...
     ipmi_si.regspacings=<sp1>,<sp2>,...
     ipmi_si.regsizes=<size1>,<size2>,...
     ipmi_si.regshifts=<shift1>,<shift2>,...
     ipmi_si.slave_addrs=<addr1>,<addr2>,...
     ipmi_si.force_kipmid=<enable1>,<enable2>,...
     ipmi_si.kipmid_max_busy_us=<ustime1>,<ustime2>,...
```

It works the same as the module parameters of the same names.

If your IPMI interface does not support interrupts and is a KCS or SMIC interface, the IPMI driver will start a kernel thread for the interface to help speed things up. This is a low-priority kernel thread that constantly polls the IPMI driver while an IPMI operation is in progress. The force_kipmid module parameter will all the user to force this thread on or off. If you force it off and don't have interrupts, the driver will run VERY slowly. Don't blame me, these interfaces suck.

Unfortunately, this thread can use a lot of CPU depending on the interface's performance. This can waste a lot of CPU and cause various issues with detecting idle CPU and using extra power. To avoid this, the kipmid_max_busy_us sets the maximum amount of time, in microseconds, that kipmid will spin before sleeping for a tick. This value sets a balance between performance and CPU waste and needs to be tuned to your needs. Maybe, someday, auto-tuning will be added, but that's not a simple thing and even the auto-tuning would need to be tuned to the user's desired performance.

The driver supports a hot add and remove of interfaces. This way, interfaces can be added or removed after the kernel is up and running. This is done using /sys/modules/ipmi_si/parameters/hotmod, which is a write-only parameter. You write a string to this interface. The string has the format:

```
<op1>[:op2[:op3...]]
```

The "op"s are:

```
add|remove,kcs|bt|smic,mem|i/o,<address>[,<opt1>[,<opt2>[,...]]]
```

You can specify more than one interface on the line. The "opt"s are:

```
rsp=<regspacing>
rsi=<regsize>
rsh=<regshift>
irq=<irq>
ipmb=<ipmb slave addr>
```

and these have the same meanings as discussed above. Note that you can also use this on the kernel command line for a more compact format for specifying an interface. Note that when removing an interface, only the first three parameters (si type, address type, and address) are used for the comparison. Any options are ignored for removing.

26.8 The SMBus Driver (SSIF)

The SMBus driver allows up to 4 SMBus devices to be configured in the system. By default, the driver will only register with something it finds in DMI or ACPI tables. You can change this at module load time (for a module) with:

```
modprobe ipmi_ssif.o
      addr=<i2caddr1>[,<i2caddr2>[,...]]
      adapter=<adapter1>[,<adapter2>[...]]
      dbg=<flags1>,<flags2>...
      slave_addrs=<addr1>,<addr2>,...
      tryacpi=[0|1] trydmi=[0|1]
      [dbg_probe=1]
```

The addresses are normal I2C addresses. The adapter is the string name of the adapter, as shown in /sys/class/i2c-adapter/i2c-<n>/name. It is NOT i2c-<n> itself. Also, the comparison is done ignoring spaces, so if the name is "This is an I2C chip" you can say adapter_name=ThisisanI2cchip. This is because it's hard to pass in spaces in kernel parameters.

The debug flags are bit flags for each BMC found, they are: IPMI messages: 1, driver state: 2, timing: 4, I2C probe: 8

The tryxxx parameters can be used to disable detecting interfaces from various sources.

Setting dbg_probe to 1 will enable debugging of the probing and detection process for BMCs on the SMBusses.

The slave_addrs specifies the IPMI address of the local BMC. This is usually 0x20 and the driver defaults to that, but in case it's not, it can be specified when the driver starts up.

Discovering the IPMI compliant BMC on the SMBus can cause devices on the I2C bus to fail. The SMBus driver writes a "Get Device ID" IPMI message as a block write to the I2C bus and waits for a response. This action can be detrimental to some I2C devices. It is highly recommended that the known I2C address be given to the SMBus driver in the smb_addr parameter unless you have DMI or ACPI data to tell the driver what to use.

When compiled into the kernel, the addresses can be specified on the kernel command line as:

```
ipmb_ssif.addr=<i2caddr1>[,<i2caddr2>[...]]
      ipmi_ssif.adapter=<adapter1>[,<adapter2>[...]]
      ipmi_ssif.dbg=<flags1>[,<flags2>[...]]
      ipmi_ssif.dbg_probe=1
      ipmi_ssif.slave_addrs=<addr1>[,<addr2>[...]]
      ipmi_ssif.tryacpi=[0|1] ipmi_ssif.trydmi=[0|1]
```

These are the same options as on the module command line.

The I2C driver does not support non-blocking access or polling, so this driver cannod to IPMI panic events, extend the watchdog at panic time, or other panic-related IPMI functions without special kernel patches and driver modifications. You can get those at the openipmi web page.

The driver supports a hot add and remove of interfaces through the I2C sysfs interface.

26.9 Other Pieces

26.10 Get the detailed info related with the IPMI device

Some users need more detailed information about a device, like where the address came from or the raw base device for the IPMI interface. You can use the IPMI smi_watcher to catch the IPMI interfaces as they come or go, and to grab the information, you can use the function ipmi_get_smi_info(), which returns the following structure:

```
struct ipmi_smi_info {
      enum ipmi_addr_src addr_src;
      struct device *dev;
      union {
              struct {
                      void *acpi_handle;
              } acpi_info;
      } addr_info;
};
```

Currently special info for only for SI_ACPI address sources is returned. Others may be added as necessary.

Note that the dev pointer is included in the above structure, and assuming ipmi_smi_get_info returns success, you must call put_device on the dev pointer.

26.11 Watchdog

A watchdog timer is provided that implements the Linux-standard watchdog timer interface. It has three module parameters that can be used to control it:

```
modprobe ipmi_watchdog timeout=<t> pretimeout=<t> action=<action type>
    preaction=<preaction type> preop=<preop type> start_now=x
    nowayout=x ifnum_to_use=n panic_wdt_timeout=<t>
```

ifnum_to_use specifies which interface the watchdog timer should use. The default is -1, which means to pick the first one registered.

The timeout is the number of seconds to the action, and the pretimeout is the amount of seconds before the reset that the pre-timeout panic will occur (if pretimeout is zero, then pretimeout will not be enabled). Note that the pretimeout is the time before the final timeout. So if the timeout is 50 seconds and the pretimeout is 10 seconds, then the pretimeout will occur in 40 second (10 seconds before the timeout). The panic_wdt_timeout is the value of timeout which is set on kernel panic, in order to let actions such as kdump to occur during panic.

The action may be "reset", "power_cycle", or "power_off", and specifies what to do when the timer times out, and defaults to "reset".

The preaction may be "pre_smi" for an indication through the SMI interface, "pre_int" for an indication through the SMI with an interrupts, and "pre_nmi" for a NMI on a preaction. This is how the driver is informed of the pretimeout.

The preop may be set to "preop_none" for no operation on a pretimeout, "preop_panic" to set the preoperation to panic, or "preop_give_data" to provide data to read from the watchdog device when the pretimeout occurs. A "pre_nmi" setting CANNOT be used with "preop_give_data" because you can't do data operations from an NMI.

When preop is set to "preop_give_data", one byte comes ready to read on the device when the pretimeout occurs. Select and fasync work on the device, as well.

If start_now is set to 1, the watchdog timer will start running as soon as the driver is loaded.

If nowayout is set to 1, the watchdog timer will not stop when the watchdog device is closed. The default value of nowayout is true if the CONFIG_WATCHDOG_NOWAYOUT option is enabled, or false if not.

When compiled into the kernel, the kernel command line is available for configuring the watchdog:

```
ipmi_watchdog.timeout=<t> ipmi_watchdog.pretimeout=<t>
      ipmi_watchdog.action=<action type>
      ipmi_watchdog.preaction=<preaction type>
      ipmi_watchdog.preop=<preop type>
      ipmi_watchdog.start_now=x
```

(continues on next page)

(continued from previous page)

```
    ipmi_watchdog.nowayout=x
    ipmi_watchdog.panic_wdt_timeout=<t>
```

The options are the same as the module parameter options.

The watchdog will panic and start a 120 second reset timeout if it gets a pre-action. During a panic or a reboot, the watchdog will start a 120 timer if it is running to make sure the reboot occurs.

Note that if you use the NMI preaction for the watchdog, you MUST NOT use the nmi watchdog. There is no reasonable way to tell if an NMI comes from the IPMI controller, so it must assume that if it gets an otherwise unhandled NMI, it must be from IPMI and it will panic immediately.

Once you open the watchdog timer, you must write a 'V' character to the device to close it, or the timer will not stop. This is a new semantic for the driver, but makes it consistent with the rest of the watchdog drivers in Linux.

26.12 Panic Timeouts

The OpenIPMI driver supports the ability to put semi-custom and custom events in the system event log if a panic occurs. if you enable the 'Generate a panic event to all BMCs on a panic' option, you will get one event on a panic in a standard IPMI event format. If you enable the 'Generate OEM events containing the panic string' option, you will also get a bunch of OEM events holding the panic string.

The field settings of the events are:

- Generator ID: 0x21 (kernel)
- EvM Rev: 0x03 (this event is formatting in IPMI 1.0 format)
- Sensor Type: 0x20 (OS critical stop sensor)
- Sensor #: The first byte of the panic string (0 if no panic string)
- Event Dir | Event Type: 0x6f (Assertion, sensor-specific event info)
- Event Data 1: 0xa1 (Runtime stop in OEM bytes 2 and 3)
- Event data 2: second byte of panic string
- Event data 3: third byte of panic string

See the IPMI spec for the details of the event layout. This event is always sent to the local management controller. It will handle routing the message to the right place

Other OEM events have the following format:

- Record ID (bytes 0-1): Set by the SEL.
- Record type (byte 2): 0xf0 (OEM non-timestamped)
- byte 3: The slave address of the card saving the panic

- byte 4: A sequence number (starting at zero) The rest of the bytes (11 bytes) are the panic string. If the panic string is longer than 11 bytes, multiple messages will be sent with increasing sequence numbers.

Because you cannot send OEM events using the standard interface, this function will attempt to find an SEL and add the events there. It will first query the capabilities of the local management controller. If it has an SEL, then they will be stored in the SEL of the local management controller. If not, and the local management controller is an event generator, the event receiver from the local management controller will be queried and the events sent to the SEL on that device. Otherwise, the events go nowhere since there is nowhere to send them.

26.13 Poweroff

If the poweroff capability is selected, the IPMI driver will install a shutdown function into the standard poweroff function pointer. This is in the ipmi_poweroff module. When the system requests a powerdown, it will send the proper IPMI commands to do this. This is supported on several platforms.

There is a module parameter named "poweroff_powercycle" that may either be zero (do a power down) or non-zero (do a power cycle, power the system off, then power it on in a few seconds). Setting ipmi_poweroff.poweroff_control=x will do the same thing on the kernel command line. The parameter is also available via the proc filesystem in /proc/sys/dev/ipmi/poweroff_powercycle. Note that if the system does not support power cycling, it will always do the power off.

The "ifnum_to_use" parameter specifies which interface the poweroff code should use. The default is -1, which means to pick the first one registered.

Note that if you have ACPI enabled, the system will prefer using ACPI to power off.

CHAPTER

TWENTYSEVEN

I3C SUBSYSTEM

27.1 I3C protocol

27.1.1 Disclaimer

This chapter will focus on aspects that matter to software developers. For everything hardware related (like how things are transmitted on the bus, how collisions are prevented, ⋯) please have a look at the I3C specification.

This document is just a brief introduction to the I3C protocol and the concepts it brings to the table. If you need more information, please refer to the MIPI I3C specification (can be downloaded here http://resources.mipi.org/mipi-i3c-v1-download).

27.1.2 Introduction

The I3C (pronounced ‘eye-three-see’) is a MIPI standardized protocol designed to overcome I2C limitations (limited speed, external signals needed for interrupts, no automatic detection of the devices connected to the bus, ⋯) while remaining power-efficient.

27.1.3 I3C Bus

An I3C bus is made of several I3C devices and possibly some I2C devices as well, but let’s focus on I3C devices for now.

An I3C device on the I3C bus can have one of the following roles:

- Master: the device is driving the bus. It’s the one in charge of initiating transactions or deciding who is allowed to talk on the bus (slave generated events are possible in I3C, see below).
- Slave: the device acts as a slave, and is not able to send frames to another slave on the bus. The device can still send events to the master on its own initiative if the master allowed it.

I3C is a multi-master protocol, so there might be several masters on a bus, though only one device can act as a master at a given time. In order to gain bus ownership, a master has to follow a specific procedure.

Each device on the I3C bus has to be assigned a dynamic address to be able to communicate. Until this is done, the device should only respond to a limited set of commands. If it has a static address (also called legacy I2C address), the device can reply to I2C transfers.

In addition to these per-device addresses, the protocol defines a broadcast address in order to address all devices on the bus.

Once a dynamic address has been assigned to a device, this address will be used for any direct communication with the device. Note that even after being assigned a dynamic address, the device should still process broadcast messages.

27.1.4 I3C Device discovery

The I3C protocol defines a mechanism to automatically discover devices present on the bus, their capabilities and the functionalities they provide. In this regard I3C is closer to a discoverable bus like USB than it is to I2C or SPI.

The discovery mechanism is called DAA (Dynamic Address Assignment), because it not only discovers devices but also assigns them a dynamic address.

During DAA, each I3C device reports 3 important things:

- BCR: Bus Characteristic Register. This 8-bit register describes the device bus related capabilities
- DCR: Device Characteristic Register. This 8-bit register describes the functionalities provided by the device
- Provisional ID: A 48-bit unique identifier. On a given bus there should be no Provisional ID collision, otherwise the discovery mechanism may fail.

27.1.5 I3C slave events

The I3C protocol allows slaves to generate events on their own, and thus allows them to take temporary control of the bus.

This mechanism is called IBI for In Band Interrupts, and as stated in the name, it allows devices to generate interrupts without requiring an external signal.

During DAA, each device on the bus has been assigned an address, and this address will serve as a priority identifier to determine who wins if 2 different devices are generating an interrupt at the same moment on the bus (the lower the dynamic address the higher the priority).

Masters are allowed to inhibit interrupts if they want to. This inhibition request can be broadcast (applies to all devices) or sent to a specific device.

27.1.6 I3C Hot-Join

The Hot-Join mechanism is similar to USB hotplug. This mechanism allows slaves to join the bus after it has been initialized by the master.

This covers the following use cases:

- the device is not powered when the bus is probed
- the device is hotplugged on the bus through an extension board

This mechanism is relying on slave events to inform the master that a new device joined the bus and is waiting for a dynamic address.

The master is then free to address the request as it wishes: ignore it or assign a dynamic address to the slave.

27.1.7 I3C transfer types

If you omit SMBus (which is just a standardization on how to access registers exposed by I2C devices), I2C has only one transfer type.

I3C defines 3 different classes of transfer in addition to I2C transfers which are here for backward compatibility with I2C devices.

I3C CCC commands

CCC (Common Command Code) commands are meant to be used for anything that is related to bus management and all features that are common to a set of devices.

CCC commands contain an 8-bit CCC ID describing the command that is executed. The MSB of this ID specifies whether this is a broadcast command (bit7 = 0) or a unicast one (bit7 = 1).

The command ID can be followed by a payload. Depending on the command, this payload is either sent by the master sending the command (write CCC command), or sent by the slave receiving the command (read CCC command). Of course, read accesses only apply to unicast commands. Note that, when sending a CCC command to a specific device, the device address is passed in the first byte of the payload.

The payload length is not explicitly passed on the bus, and should be extracted from the CCC ID.

Note that vendors can use a dedicated range of CCC IDs for their own commands (0x61-0x7f and 0xe0-0xef).

I3C Private SDR transfers

Private SDR (Single Data Rate) transfers should be used for anything that is device specific and does not require high transfer speed.

It is the equivalent of I2C transfers but in the I3C world. Each transfer is passed the device address (dynamic address assigned during DAA), a payload and a direction.

The only difference with I2C is that the transfer is much faster (typical clock frequency is 12.5MHz).

I3C HDR commands

HDR commands should be used for anything that is device specific and requires high transfer speed.

The first thing attached to an HDR command is the HDR mode. There are currently 3 different modes defined by the I3C specification (refer to the specification for more details):

- HDR-DDR: Double Data Rate mode
- HDR-TSP: Ternary Symbol Pure. Only usable on busses with no I2C devices
- HDR-TSL: Ternary Symbol Legacy. Usable on busses with I2C devices

When sending an HDR command, the whole bus has to enter HDR mode, which is done using a broadcast CCC command. Once the bus has entered a specific HDR mode, the master sends the HDR command. An HDR command is made of:

- one 16-bits command word in big endian
- N 16-bits data words in big endian

Those words may be wrapped with specific preambles/post-ambles which depend on the chosen HDR mode and are detailed here (see the specification for more details).

The 16-bits command word is made of:

- bit[15]: direction bit, read is 1, write is 0
- bit[14:8]: command code. Identifies the command being executed, the amount of data words and their meaning
- bit[7:1]: I3C address of the device this command is addressed to
- bit[0]: reserved/parity-bit

27.1.8 Backward compatibility with I2C devices

The I3C protocol has been designed to be backward compatible with I2C devices. This backward compatibility allows one to connect a mix of I2C and I3C devices on the same bus, though, in order to be really efficient, I2C devices should be equipped with 50 ns spike filters.

I2C devices can't be discovered like I3C ones and have to be statically declared. In order to let the master know what these devices are capable of (both in terms of bus related limitations and functionalities), the software has to provide some information, which is done through the LVR (Legacy I2C Virtual Register).

27.2 I3C device driver API

enum **i3c_error_code**
I3C error codes

Constants

I3C_ERROR_UNKNOWN unknown error, usually means the error is not I3C related

I3C_ERROR_M0 M0 error

I3C_ERROR_M1 M1 error

I3C_ERROR_M2 M2 error

Description

These are the standard error codes as defined by the I3C specification. When -EIO is returned by the `i3c_device_do_priv_xfers()` or i3c_device_send_hdr_cmds() one can check the error code in `struct i3c_priv_xfer.err` or `struct i3c_hdr_cmd`.err to get a better idea of what went wrong.

enum **i3c_hdr_mode**
HDR mode ids

Constants

I3C_HDR_DDR DDR mode

I3C_HDR_TSP TSP mode

I3C_HDR_TSL TSL mode

struct **i3c_priv_xfer**
I3C SDR private transfer

Definition

```
struct i3c_priv_xfer {
  u8 rnw;
  u16 len;
  union {
    void *in;
    const void *out;
  } data;
```

(continues on next page)

(continued from previous page)

```
  enum i3c_error_code err;
};
```

Members

rnw encodes the transfer direction. true for a read, false for a write

len transfer length in bytes of the transfer

data input/output buffer

data.in input buffer. Must point to a DMA-able buffer

data.out output buffer. Must point to a DMA-able buffer

err I3C error code

enum **i3c_dcr**
I3C DCR values

Constants

I3C_DCR_GENERIC_DEVICE generic I3C device

struct **i3c_device_info**
I3C device information

Definition

```
struct i3c_device_info {
  u64 pid;
  u8 bcr;
  u8 dcr;
  u8 static_addr;
  u8 dyn_addr;
  u8 hdr_cap;
  u8 max_read_ds;
  u8 max_write_ds;
  u8 max_ibi_len;
  u32 max_read_turnaround;
  u16 max_read_len;
  u16 max_write_len;
};
```

Members

pid Provisional ID

bcr Bus Characteristic Register

dcr Device Characteristic Register

static_addr static/I2C address

dyn_addr dynamic address

hdr_cap supported HDR modes

max_read_ds max read speed information

max_write_ds max write speed information

max_ibi_len max IBI payload length

max_read_turnaround max read turn-around time in micro-seconds

max_read_len max private SDR read length in bytes

max_write_len max private SDR write length in bytes

Description

These are all basic information that should be advertised by an I3C device. Some of them are optional depending on the device type and device capabilities. For each I3C slave attached to a master with `i3c_master_add_i3c_dev_locked()`, the core will send the relevant CCC command to retrieve these data.

struct **i3c_driver**
I3C device driver

Definition

```
struct i3c_driver {
  struct device_driver driver;
  int (*probe)(struct i3c_device *dev);
  int (*remove)(struct i3c_device *dev);
  const struct i3c_device_id *id_table;
};
```

Members

driver inherit from device_driver

probe I3C device probe method

remove I3C device remove method

id_table I3C device match table. Will be used by the framework to decide which device to bind to this driver

module_i3c_driver(__drv)
Register a module providing an I3C driver

Parameters

__drv the I3C driver to register

Description

Provide generic init/exit functions that simply register/unregister an I3C driver. Should be used by any driver that does not require extra init/cleanup steps.

int **i3c_i2c_driver_register**(struct i3c_driver * i3cdrv, struct i2c_driver * i2cdrv)
Register an i2c and an i3c driver

Parameters

struct i3c_driver * i3cdrv the I3C driver to register

struct i2c_driver * i2cdrv the I2C driver to register

Description

This function registers both **i2cdev** and **i3cdev**, and fails if one of these registrations fails. This is mainly useful for devices that support both I2C and I3C modes. Note that when CONFIG_I3C is not enabled, this function only registers the I2C driver.

Return

0 if both registrations succeeds, a negative error code otherwise.

void **i3c_i2c_driver_unregister**(struct i3c_driver * i3cdrv, struct i2c_driver * i2cdrv)
Unregister an i2c and an i3c driver

Parameters

struct i3c_driver * i3cdrv the I3C driver to register

struct i2c_driver * i2cdrv the I2C driver to register

Description

This function unregisters both **i3cdrv** and **i2cdrv**. Note that when CONFIG_I3C is not enabled, this function only unregisters the **i2cdrv**.

module_i3c_i2c_driver(__i3cdrv, __i2cdrv)
Register a module providing an I3C and an I2C driver

Parameters

__i3cdrv the I3C driver to register

__i2cdrv the I3C driver to register

Description

Provide generic init/exit functions that simply register/unregister an I3C and an I2C driver. This macro can be used even if CONFIG_I3C is disabled, in this case, only the I2C driver will be registered. Should be used by any driver that does not require extra init/cleanup steps.

struct **i3c_ibi_setup**
IBI setup object

Definition

```
struct i3c_ibi_setup {
  unsigned int max_payload_len;
  unsigned int num_slots;
  void (*handler)(struct i3c_device *dev, const struct i3c_ibi_payload␣
↪*payload);
};
```

Members

max_payload_len maximum length of the payload associated to an IBI. If one IBI appears to have a payload that is bigger than this number, the IBI will be rejected.

num_slots number of pre-allocated IBI slots. This should be chosen so that the system never runs out of IBI slots, otherwise you' ll lose IBIs.

handler IBI handler, every time an IBI is received. This handler is called in a workqueue context. It is allowed to sleep and send new messages on the bus, though it's recommended to keep the processing done there as fast as possible to avoid delaying processing of other queued on the same workqueue.

Description

Temporary structure used to pass information to `i3c_device_request_ibi()`. This object can be allocated on the stack since `i3c_device_request_ibi()` copies every bit of information and do not use it after `i3c_device_request_ibi()` has returned.

int **i3c_device_do_priv_xfers**(struct i3c_device * dev, struct i3c_priv_xfer * xfers, int nxfers)
do I3C SDR private transfers directed to a specific device

Parameters

struct i3c_device * dev device with which the transfers should be done

struct i3c_priv_xfer * xfers array of transfers

int nxfers number of transfers

Description

Initiate one or several private SDR transfers with **dev**.

This function can sleep and thus cannot be called in atomic context.

Return

0 in case of success, a negative error core otherwise.

void **i3c_device_get_info**(struct i3c_device * dev, struct i3c_device_info * info)
get I3C device information

Parameters

struct i3c_device * dev device we want information on

struct i3c_device_info * info the information object to fill in

Description

Retrieve I3C dev info.

int **i3c_device_disable_ibi**(struct i3c_device * dev)
Disable IBIs coming from a specific device

Parameters

struct i3c_device * dev device on which IBIs should be disabled

Description

This function disable IBIs coming from a specific device and wait for all pending IBIs to be processed.

Return

0 in case of success, a negative error core otherwise.

int **i3c_device_enable_ibi**(struct i3c_device * dev)
Enable IBIs coming from a specific device

Parameters

struct i3c_device * dev device on which IBIs should be enabled

Description

This function enable IBIs coming from a specific device and wait for all pending IBIs to be processed. This should be called on a device where `i3c_device_request_ibi()` has succeeded.

Note that IBIs from this device might be received before this function returns to its caller.

Return

0 in case of success, a negative error core otherwise.

int **i3c_device_request_ibi**(struct i3c_device * dev, const struct i3c_ibi_setup * req)
Request an IBI

Parameters

struct i3c_device * dev device for which we should enable IBIs

const struct i3c_ibi_setup * req setup requested for this IBI

Description

This function is responsible for pre-allocating all resources needed to process IBIs coming from **dev**. When this function returns, the IBI is not enabled until `i3c_device_enable_ibi()` is called.

Return

0 in case of success, a negative error core otherwise.

void **i3c_device_free_ibi**(struct i3c_device * dev)
Free all resources needed for IBI handling

Parameters

struct i3c_device * dev device on which you want to release IBI resources

Description

This function is responsible for de-allocating resources previously allocated by `i3c_device_request_ibi()`. It should be called after disabling IBIs with `i3c_device_disable_ibi()`.

struct device * **i3cdev_to_dev**(struct i3c_device * i3cdev)
Returns the device embedded in **i3cdev**

Parameters

struct i3c_device * i3cdev I3C device

Return

a pointer to a device object.

struct i3c_device * **dev_to_i3cdev**(struct device * dev)
Returns the I3C device containing **dev**

Parameters

struct device * dev device object

Return

a pointer to an I3C device object.

const struct i3c_device_id * **i3c_device_match_id**(struct i3c_device * i3cdev, const struct i3c_device_id * id_table)
Returns the i3c_device_id entry matching **i3cdev**

Parameters

struct i3c_device * i3cdev I3C device

const struct i3c_device_id * id_table I3C device match table

Return

a pointer to an i3c_device_id object or NULL if there's no match.

int **i3c_driver_register_with_owner**(struct i3c_driver * drv, struct module * owner)
register an I3C device driver

Parameters

struct i3c_driver * drv driver to register

struct module * owner module that owns this driver

Description

Register **drv** to the core.

Return

0 in case of success, a negative error core otherwise.

void **i3c_driver_unregister**(struct i3c_driver * drv)
unregister an I3C device driver

Parameters

struct i3c_driver * drv driver to unregister

Description

Unregister **drv**.

27.3 I3C master controller driver API

void **i3c_bus_maintenance_lock**(struct i3c_bus * bus)
Lock the bus for a maintenance operation

Parameters

struct i3c_bus * bus I3C bus to take the lock on

Description

This function takes the bus lock so that no other operations can occur on the bus. This is needed for all kind of bus maintenance operation, like - enabling/disabling slave events - re-triggering DAA - changing the dynamic address of a device - relinquishing mastership - ⋯

The reason for this kind of locking is that we don't want drivers and core logic to rely on I3C device information that could be changed behind their back.

void **i3c_bus_maintenance_unlock**(struct i3c_bus * bus)
Release the bus lock after a maintenance operation

Parameters

struct i3c_bus * bus I3C bus to release the lock on

Description

Should be called when the bus maintenance operation is done. See `i3c_bus_maintenance_lock()` for more details on what these maintenance operations are.

void **i3c_bus_normaluse_lock**(struct i3c_bus * bus)
Lock the bus for a normal operation

Parameters

struct i3c_bus * bus I3C bus to take the lock on

Description

This function takes the bus lock for any operation that is not a maintenance operation (see `i3c_bus_maintenance_lock()` for a non-exhaustive list of maintenance operations). Basically all communications with I3C devices are normal operations (HDR, SDR transfers or CCC commands that do not change bus state or I3C dynamic address).

Note that this lock is not guaranteeing serialization of normal operations. In other words, transfer requests passed to the I3C master can be submitted in parallel and I3C master drivers have to use their own locking to make sure two different communications are not inter-mixed, or access to the output/input queue is not done while the engine is busy.

void **i3c_bus_normaluse_unlock**(struct i3c_bus * bus)
Release the bus lock after a normal operation

Parameters

struct i3c_bus * bus I3C bus to release the lock on

Description

Should be called when a normal operation is done. See `i3c_bus_normaluse_lock()` for more details on what these normal operations are.

int **i3c_master_get_free_addr**(struct i3c_master_controller * master, u8 start_addr)
get a free address on the bus

Parameters

struct i3c_master_controller * master I3C master object

u8 start_addr where to start searching

Description

This function must be called with the bus lock held in write mode.

Return

the first free address starting at **start_addr** (included) or -ENOMEM if there's no more address available.

int **i3c_master_entdaa_locked**(struct i3c_master_controller * master)
start a DAA (Dynamic Address Assignment) procedure

Parameters

struct i3c_master_controller * master master used to send frames on the bus

Description

Send a ENTDAA CCC command to start a DAA procedure.

Note that this function only sends the ENTDAA CCC command, all the logic behind dynamic address assignment has to be handled in the I3C master driver.

This function must be called with the bus lock held in write mode.

Return

0 in case of success, a positive I3C error code if the error is one of the official Mx error codes, and a negative error code otherwise.

int **i3c_master_disec_locked**(struct i3c_master_controller * master, u8 addr, u8 evts)
send a DISEC CCC command

Parameters

struct i3c_master_controller * master master used to send frames on the bus

u8 addr a valid I3C slave address or `I3C_BROADCAST_ADDR`

u8 evts events to disable

Description

Send a DISEC CCC command to disable some or all events coming from a specific slave, or all devices if **addr** is `I3C_BROADCAST_ADDR`.

This function must be called with the bus lock held in write mode.

Return

0 in case of success, a positive I3C error code if the error is one of the official Mx error codes, and a negative error code otherwise.

int **i3c_master_enec_locked**(struct i3c_master_controller * master, u8 addr, u8 evts)
send an ENEC CCC command

Parameters

struct i3c_master_controller * master master used to send frames on the bus

u8 addr a valid I3C slave address or `I3C_BROADCAST_ADDR`

u8 evts events to disable

Description

Sends an ENEC CCC command to enable some or all events coming from a specific slave, or all devices if **addr** is `I3C_BROADCAST_ADDR`.

This function must be called with the bus lock held in write mode.

Return

0 in case of success, a positive I3C error code if the error is one of the official Mx error codes, and a negative error code otherwise.

int **i3c_master_defslvs_locked**(struct i3c_master_controller * master)
send a DEFSLVS CCC command

Parameters

struct i3c_master_controller * master master used to send frames on the bus

Description

Send a DEFSLVS CCC command containing all the devices known to the **master**. This is useful when you have secondary masters on the bus to propagate device information.

This should be called after all I3C devices have been discovered (in other words, after the DAA procedure has finished) and instantiated in `i3c_master_controller_ops->bus_init()`. It should also be called if a master ACKed an Hot-Join request and assigned a dynamic address to the device joining the bus.

This function must be called with the bus lock held in write mode.

Return

0 in case of success, a positive I3C error code if the error is one of the official Mx error codes, and a negative error code otherwise.

int **i3c_master_do_daa**(struct i3c_master_controller * master)
do a DAA (Dynamic Address Assignment)

Parameters

struct i3c_master_controller * master master doing the DAA

Description

This function is instantiating an I3C device object and adding it to the I3C device list. All device information are automatically retrieved using standard CCC commands.

The I3C device object is returned in case the master wants to attach private data to it using `i3c_dev_set_master_data()`.

This function must be called with the bus lock held in write mode.

Return

a 0 in case of success, an negative error code otherwise.

int **i3c_master_set_info**(struct i3c_master_controller * master, const struct i3c_device_info * info)
set master device information

Parameters

struct i3c_master_controller * master master used to send frames on the bus

const struct i3c_device_info * info I3C device information

Description

Set master device info. This should be called from `i3c_master_controller_ops->bus_init()`.

Not all `i3c_device_info` fields are meaningful for a master device. Here is a list of fields that should be properly filled:

- `i3c_device_info->dyn_addr`
- `i3c_device_info->bcr`
- `i3c_device_info->dcr`
- `i3c_device_info->pid`
- `i3c_device_info->hdr_cap` if `I3C_BCR_HDR_CAP` bit is set in `i3c_device_info->bcr`

This function must be called with the bus lock held in maintenance mode.

Return

0 if **info** contains valid information (not every piece of information can be checked, but we can at least make sure **info->dyn_addr** and **info->bcr** are correct), -EINVAL otherwise.

int **i3c_master_bus_init**(struct i3c_master_controller * master)
initialize an I3C bus

Parameters

struct i3c_master_controller * master main master initializing the bus

Description

This function is following all initialisation steps described in the I3C specification:

1. Attach I2C and statically defined I3C devs to the master so that the master can fill its internal device table appropriately
2. Call `i3c_master_controller_ops->bus_init()` method to initialize the master controller. That's usually where the bus mode is selected (pure bus or mixed fast/slow bus)
3. Instruct all devices on the bus to drop their dynamic address. This is particularly important when the bus was previously configured by someone else (for example the bootloader)
4. Disable all slave events.
5. Pre-assign dynamic addresses requested by the FW with SETDASA for I3C devices that have a static address
6. Do a DAA (Dynamic Address Assignment) to assign dynamic addresses to all remaining I3C devices

Once this is done, all I3C and I2C devices should be usable.

Return

a 0 in case of success, an negative error code otherwise.

int **i3c_master_add_i3c_dev_locked**(struct i3c_master_controller * master, u8 addr)

add an I3C slave to the bus

Parameters

struct i3c_master_controller * master master used to send frames on the bus

u8 addr I3C slave dynamic address assigned to the device

Description

This function is instantiating an I3C device object and adding it to the I3C device list. All device information are automatically retrieved using standard CCC commands.

The I3C device object is returned in case the master wants to attach private data to it using `i3c_dev_set_master_data()`.

This function must be called with the bus lock held in write mode.

Return

a 0 in case of success, an negative error code otherwise.

void **i3c_master_queue_ibi**(struct i3c_dev_desc * dev, struct i3c_ibi_slot * slot)

Queue an IBI

Parameters

struct i3c_dev_desc * dev the device this IBI is coming from

struct i3c_ibi_slot * slot the IBI slot used to store the payload

Description

Queue an IBI to the controller workqueue. The IBI handler attached to the dev will be called from a workqueue context.

void **i3c_generic_ibi_free_pool**(struct i3c_generic_ibi_pool * pool)
Free a generic IBI pool

Parameters

struct i3c_generic_ibi_pool * pool the IBI pool to free

Description

Free all IBI slots allated by a generic IBI pool.

struct i3c_generic_ibi_pool * **i3c_generic_ibi_alloc_pool**(struct i3c_dev_desc * dev, const struct i3c_ibi_setup * req)
Create a generic IBI pool

Parameters

struct i3c_dev_desc * dev the device this pool will be used for

const struct i3c_ibi_setup * req IBI setup request describing what the device driver expects

Description

Create a generic IBI pool based on the information provided in **req**.

Return

a valid IBI pool in case of success, an ERR_PTR() otherwise.

struct i3c_ibi_slot * **i3c_generic_ibi_get_free_slot**(struct i3c_generic_ibi_pool * pool)
Get a free slot from a generic IBI pool

Parameters

struct i3c_generic_ibi_pool * pool the pool to query an IBI slot on

Description

Search for a free slot in a generic IBI pool. The slot should be returned to the pool using `i3c_generic_ibi_recycle_slot()` when it's no longer needed.

Return

a pointer to a free slot, or NULL if there's no free slot available.

void **i3c_generic_ibi_recycle_slot**(struct i3c_generic_ibi_pool * pool, struct i3c_ibi_slot * s)
Return a slot to a generic IBI pool

Parameters

struct i3c_generic_ibi_pool * pool the pool to return the IBI slot to

struct i3c_ibi_slot * s IBI slot to recycle

Description

Add an IBI slot back to its generic IBI pool. Should be called from the master driver struct_master_controller_ops->recycle_ibi() method.

int **i3c_master_register**(struct i3c_master_controller * master, struct device * parent, const struct i3c_master_controller_ops * ops, bool secondary)
register an I3C master

Parameters

struct i3c_master_controller * master master used to send frames on the bus

struct device * parent the parent device (the one that provides this I3C master controller)

const struct i3c_master_controller_ops * ops the master controller operations

bool secondary true if you are registering a secondary master. Will return -ENOTSUPP if set to true since secondary masters are not yet supported

Description

This function takes care of everything for you:

- creates and initializes the I3C bus
- populates the bus with static I2C devs if **parent->of_node** is not NULL
- registers all I3C devices added by the controller during bus initialization
- registers the I2C adapter and all I2C devices

Return

0 in case of success, a negative error code otherwise.

int **i3c_master_unregister**(struct i3c_master_controller * master)
unregister an I3C master

Parameters

struct i3c_master_controller * master master used to send frames on the bus

Description

Basically undo everything done in `i3c_master_register()`.

Return

0 in case of success, a negative error code otherwise.

struct **i3c_i2c_dev_desc**
Common part of the I3C/I2C device descriptor

Definition

```
struct i3c_i2c_dev_desc {
  struct list_head node;
  struct i3c_master_controller *master;
  void *master_priv;
};
```

Members

node node element used to insert the slot into the I2C or I3C device list

master I3C master that instantiated this device. Will be used to do I2C/I3C transfers

master_priv master private data assigned to the device. Can be used to add master specific information

Description

This structure is describing common I3C/I2C dev information.

struct **i2c_dev_boardinfo**
I2C device board information

Definition

```
struct i2c_dev_boardinfo {
  struct list_head node;
  struct i2c_board_info base;
  u8 lvr;
};
```

Members

node used to insert the boardinfo object in the I2C boardinfo list

base regular I2C board information

lvr LVR (Legacy Virtual Register) needed by the I3C core to know about the I2C device limitations

Description

This structure is used to attach board-level information to an I2C device. Each I2C device connected on the I3C bus should have one.

struct **i2c_dev_desc**
I2C device descriptor

Definition

```
struct i2c_dev_desc {
  struct i3c_i2c_dev_desc common;
  const struct i2c_dev_boardinfo *boardinfo;
  struct i2c_client *dev;
  u16 addr;
  u8 lvr;
};
```

Members

common common part of the I2C device descriptor

boardinfo pointer to the boardinfo attached to this I2C device

dev I2C device object registered to the I2C framework

addr I2C device address

lvr LVR (Legacy Virtual Register) needed by the I3C core to know about the I2C device limitations

Description

Each I2C device connected on the bus will have an i2c_dev_desc. This object is created by the core and later attached to the controller using `struct_i3c_master_controller->ops->`attach_i2c_dev().

`struct_i2c_dev_desc` is the internal representation of an I2C device connected on an I3C bus. This object is also passed to all `struct_i3c_master_controller_ops` hooks.

struct **i3c_ibi_slot**
I3C IBI (In-Band Interrupt) slot

Definition

```
struct i3c_ibi_slot {
  struct work_struct work;
  struct i3c_dev_desc *dev;
  unsigned int len;
  void *data;
};
```

Members

work work associated to this slot. The IBI handler will be called from there

dev the I3C device that has generated this IBI

len length of the payload associated to this IBI

data payload buffer

Description

An IBI slot is an object pre-allocated by the controller and used when an IBI comes in. Every time an IBI comes in, the I3C master driver should find a free IBI slot in its IBI slot pool, retrieve the IBI payload and queue the IBI using `i3c_master_queue_ibi()`.

How IBI slots are allocated is left to the I3C master driver, though, for simple kmalloc-based allocation, the generic IBI slot pool can be used.

struct **i3c_device_ibi_info**
IBI information attached to a specific device

Definition

```
struct i3c_device_ibi_info {
  struct completion all_ibis_handled;
  atomic_t pending_ibis;
  unsigned int max_payload_len;
  unsigned int num_slots;
```

(continues on next page)

(continued from previous page)

```
  unsigned int enabled;
  void (*handler)(struct i3c_device *dev, const struct i3c_ibi_payload␣
↪*payload);
};
```

Members

all_ibis_handled used to be informed when no more IBIs are waiting to be processed. Used by `i3c_device_disable_ibi()` to wait for all IBIs to be dequeued

pending_ibis count the number of pending IBIs. Each pending IBI has its work element queued to the controller workqueue

max_payload_len maximum payload length for an IBI coming from this device. this value is specified when calling `i3c_device_request_ibi()` and should not change at run time. All messages IBIs exceeding this limit should be rejected by the master

num_slots number of IBI slots reserved for this device

enabled reflect the IBI status

handler IBI handler specified at `i3c_device_request_ibi()` call time. This handler will be called from the controller workqueue, and as such is allowed to sleep (though it is recommended to process the IBI as fast as possible to not stall processing of other IBIs queued on the same workqueue). New I3C messages can be sent from the IBI handler

Description

The `struct i3c_device_ibi_info` object is allocated when `i3c_device_request_ibi()` is called and attached to a specific device. This object is here to manage IBIs coming from a specific I3C device.

Note that this structure is the generic view of the IBI management infrastructure. I3C master drivers may have their own internal representation which they can associate to the device using controller-private data.

struct **i3c_dev_boardinfo**
I3C device board information

Definition

```
struct i3c_dev_boardinfo {
  struct list_head node;
  u8 init_dyn_addr;
  u8 static_addr;
  u64 pid;
  struct device_node *of_node;
};
```

Members

node used to insert the boardinfo object in the I3C boardinfo list

init_dyn_addr initial dynamic address requested by the FW. We provide no guarantee that the device will end up using this address, but try our best to assign

this specific address to the device

static_addr static address the I3C device listen on before it's been assigned a dynamic address by the master. Will be used during bus initialization to assign it a specific dynamic address before starting DAA (Dynamic Address Assignment)

pid I3C Provisional ID exposed by the device. This is a unique identifier that may be used to attach boardinfo to i3c_dev_desc when the device does not have a static address

of_node optional DT node in case the device has been described in the DT

Description

This structure is used to attach board-level information to an I3C device. Not all I3C devices connected on the bus will have a boardinfo. It's only needed if you want to attach extra resources to a device or assign it a specific dynamic address.

struct **i3c_dev_desc**
I3C device descriptor

Definition

```
struct i3c_dev_desc {
  struct i3c_i2c_dev_desc common;
  struct i3c_device_info info;
  struct mutex ibi_lock;
  struct i3c_device_ibi_info *ibi;
  struct i3c_device *dev;
  const struct i3c_dev_boardinfo *boardinfo;
};
```

Members

common common part of the I3C device descriptor

info I3C device information. Will be automatically filled when you create your device with `i3c_master_add_i3c_dev_locked()`

ibi_lock lock used to protect the `struct_i3c_device->ibi`

ibi IBI info attached to a device. Should be NULL until `i3c_device_request_ibi()` is called

dev pointer to the I3C device object exposed to I3C device drivers. This should never be accessed from I3C master controller drivers. Only core code should manipulate it in when updating the dev <-> desc link or when propagating IBI events to the driver

boardinfo pointer to the boardinfo attached to this I3C device

Description

Internal representation of an I3C device. This object is only used by the core and passed to I3C master controller drivers when they're requested to do some operations on the device. The core maintains the link between the internal I3C dev descriptor and the object exposed to the I3C device drivers (`struct_i3c_device`).

struct **i3c_device**
I3C device object

Definition

```
struct i3c_device {
  struct device dev;
  struct i3c_dev_desc *desc;
  struct i3c_bus *bus;
};
```

Members

dev device object to register the I3C dev to the device model

desc pointer to an i3c device descriptor object. This link is updated every time the I3C device is rediscovered with a different dynamic address assigned

bus I3C bus this device is attached to

Description

I3C device object exposed to I3C device drivers. The takes care of linking this object to the relevant `struct_i3c_dev_desc` one. All I3C devs on the I3C bus are represented, including I3C masters. For each of them, we have an instance of `struct i3c_device`.

enum **i3c_bus_mode**
I3C bus mode

Constants

I3C_BUS_MODE_PURE only I3C devices are connected to the bus. No limitation expected

I3C_BUS_MODE_MIXED_FAST I2C devices with 50ns spike filter are present on the bus. The only impact in this mode is that the high SCL pulse has to stay below 50ns to trick I2C devices when transmitting I3C frames

I3C_BUS_MODE_MIXED_LIMITED I2C devices without 50ns spike filter are present on the bus. However they allow compliance up to the maximum SDR SCL clock frequency.

I3C_BUS_MODE_MIXED_SLOW I2C devices without 50ns spike filter are present on the bus

enum **i3c_addr_slot_status**
I3C address slot status

Constants

I3C_ADDR_SLOT_FREE address is free

I3C_ADDR_SLOT_RSVD address is reserved

I3C_ADDR_SLOT_I2C_DEV address is assigned to an I2C device

I3C_ADDR_SLOT_I3C_DEV address is assigned to an I3C device

I3C_ADDR_SLOT_STATUS_MASK address slot mask

Description

On an I3C bus, addresses are assigned dynamically, and we need to know which addresses are free to use and which ones are already assigned.

Addresses marked as reserved are those reserved by the I3C protocol (broadcast address, ⋯).

struct **i3c_bus**
I3C bus object

Definition

```
struct i3c_bus {
  struct i3c_dev_desc *cur_master;
  int id;
  unsigned long addrslots[((I2C_MAX_ADDR + 1) * 2) / BITS_PER_LONG];
  enum i3c_bus_mode mode;
  struct {
    unsigned long i3c;
    unsigned long i2c;
  } scl_rate;
  struct {
    struct list_head i3c;
    struct list_head i2c;
  } devs;
  struct rw_semaphore lock;
};
```

Members

cur_master I3C master currently driving the bus. Since I3C is multi-master this can change over the time. Will be used to let a master know whether it needs to request bus ownership before sending a frame or not

id bus ID. Assigned by the framework when register the bus

addrslots a bitmap with 2-bits per-slot to encode the address status and ease the DAA (Dynamic Address Assignment) procedure (see `enum i3c_addr_slot_status`)

mode bus mode (see `enum i3c_bus_mode`)

scl_rate SCL signal rate for I3C and I2C mode

scl_rate.i3c maximum rate for the clock signal when doing I3C SDR/priv transfers

scl_rate.i2c maximum rate for the clock signal when doing I2C transfers

devs 2 lists containing all I3C/I2C devices connected to the bus

devs.i3c contains a list of I3C device descriptors representing I3C devices connected on the bus and successfully attached to the I3C master

devs.i2c contains a list of I2C device descriptors representing I2C devices connected on the bus and successfully attached to the I3C master

lock read/write lock on the bus. This is needed to protect against operations that have an impact on the whole bus and the devices connected to it. For example, when asking slaves to drop their dynamic address (RSTDAA CCC), we need to

make sure no one is trying to send I3C frames to these devices. Note that this lock does not protect against concurrency between devices: several drivers can send different I3C/I2C frames through the same master in parallel. This is the responsibility of the master to guarantee that frames are actually sent sequentially and not interlaced

Description

The I3C bus is represented with its own object and not implicitly described by the I3C master to cope with the multi-master functionality, where one bus can be shared amongst several masters, each of them requesting bus ownership when they need to.

struct **i3c_master_controller_ops**
I3C master methods

Definition

```
struct i3c_master_controller_ops {
  int (*bus_init)(struct i3c_master_controller *master);
  void (*bus_cleanup)(struct i3c_master_controller *master);
  int (*attach_i3c_dev)(struct i3c_dev_desc *dev);
  int (*reattach_i3c_dev)(struct i3c_dev_desc *dev, u8 old_dyn_addr);
  void (*detach_i3c_dev)(struct i3c_dev_desc *dev);
  int (*do_daa)(struct i3c_master_controller *master);
  bool (*supports_ccc_cmd)(struct i3c_master_controller *master, const␣
↪struct i3c_ccc_cmd *cmd);
  int (*send_ccc_cmd)(struct i3c_master_controller *master, struct i3c_ccc_
↪cmd *cmd);
  int (*priv_xfers)(struct i3c_dev_desc *dev,struct i3c_priv_xfer *xfers,␣
↪int nxfers);
  int (*attach_i2c_dev)(struct i2c_dev_desc *dev);
  void (*detach_i2c_dev)(struct i2c_dev_desc *dev);
  int (*i2c_xfers)(struct i2c_dev_desc *dev, const struct i2c_msg *xfers,␣
↪int nxfers);
  int (*request_ibi)(struct i3c_dev_desc *dev, const struct i3c_ibi_setup␣
↪*req);
  void (*free_ibi)(struct i3c_dev_desc *dev);
  int (*enable_ibi)(struct i3c_dev_desc *dev);
  int (*disable_ibi)(struct i3c_dev_desc *dev);
  void (*recycle_ibi_slot)(struct i3c_dev_desc *dev, struct i3c_ibi_slot␣
↪*slot);
};
```

Members

bus_init hook responsible for the I3C bus initialization. You should at least call master_set_info() from there and set the bus mode. You can also put controller specific initialization in there. This method is mandatory.

bus_cleanup cleanup everything done in `i3c_master_controller_ops->bus_init()`. This method is optional.

attach_i3c_dev called every time an I3C device is attached to the bus. It can be after a DAA or when a device is statically declared by the FW, in which case it will only have a static address and the dynamic address will be 0. When this function is called, device information have not been retrieved yet. This

is a good place to attach master controller specific data to I3C devices. This method is optional.

reattach_i3c_dev called every time an I3C device has its addressed changed. It can be because the device has been powered down and has lost its address, or it can happen when a device had a static address and has been assigned a dynamic address with SETDASA. This method is optional.

detach_i3c_dev called when an I3C device is detached from the bus. Usually happens when the master device is unregistered. This method is optional.

do_daa do a DAA (Dynamic Address Assignment) procedure. This is procedure should send an ENTDAA CCC command and then add all devices discovered sure the DAA using `i3c_master_add_i3c_dev_locked()`. Add devices added with `i3c_master_add_i3c_dev_locked()` will then be attached or reattached to the controller. This method is mandatory.

supports_ccc_cmd should return true if the CCC command is supported, false otherwise. This method is optional, if not provided the core assumes all CCC commands are supported.

send_ccc_cmd send a CCC command This method is mandatory.

priv_xfers do one or several private I3C SDR transfers This method is mandatory.

attach_i2c_dev called every time an I2C device is attached to the bus. This is a good place to attach master controller specific data to I2C devices. This method is optional.

detach_i2c_dev called when an I2C device is detached from the bus. Usually happens when the master device is unregistered. This method is optional.

i2c_xfers do one or several I2C transfers. Note that, unlike i3c transfers, the core does not guarantee that buffers attached to the transfers are DMA-safe. If drivers want to have DMA-safe buffers, they should use the `i2c_get_dma_safe_msg_buf()` and `i2c_put_dma_safe_msg_buf()` helpers provided by the I2C framework. This method is mandatory.

request_ibi attach an IBI handler to an I3C device. This implies defining an IBI handler and the constraints of the IBI (maximum payload length and number of pre-allocated slots). Some controllers support less IBI-capable devices than regular devices, so this method might return `-EBUSY` if there' s no more space for an extra IBI registration This method is optional.

free_ibi free an IBI previously requested with ->request_ibi(). The IBI should have been disabled with ->disable_irq() prior to that This method is mandatory only if ->request_ibi is not NULL.

enable_ibi enable the IBI. Only valid if ->request_ibi() has been called prior to ->enable_ibi(). The controller should first enable the IBI on the controller end (for example, unmask the hardware IRQ) and then send the ENEC CCC command (with the IBI flag set) to the I3C device. This method is mandatory only if ->request_ibi is not NULL.

disable_ibi disable an IBI. First send the DISEC CCC command with the IBI flag set and then deactivate the hardware IRQ on the controller end. This method is mandatory only if ->request_ibi is not NULL.

recycle_ibi_slot recycle an IBI slot. Called every time an IBI has been processed by its handler. The IBI slot should be put back in the IBI slot pool so that the controller can re-use it for a future IBI This method is mandatory only if ->request_ibi is not NULL.

struct **i3c_master_controller**
I3C master controller object

Definition

```
struct i3c_master_controller {
  struct device dev;
  struct i3c_dev_desc *this;
  struct i2c_adapter i2c;
  const struct i3c_master_controller_ops *ops;
  unsigned int secondary : 1;
  unsigned int init_done : 1;
  struct {
    struct list_head i3c;
    struct list_head i2c;
  } boardinfo;
  struct i3c_bus bus;
  struct workqueue_struct *wq;
};
```

Members

dev device to be registered to the device-model

this an I3C device object representing this master. This device will be added to the list of I3C devs available on the bus

i2c I2C adapter used for backward compatibility. This adapter is registered to the I2C subsystem to be as transparent as possible to existing I2C drivers

ops master operations. See `struct i3c_master_controller_ops`

secondary true if the master is a secondary master

init_done true when the bus initialization is done

boardinfo board-level information attached to devices connected on the bus

boardinfo.i3c list of I3C boardinfo objects

boardinfo.i2c list of I2C boardinfo objects

bus I3C bus exposed by this master

wq workqueue used to execute IBI handlers. Can also be used by master drivers if they need to postpone operations that need to take place in a thread context. Typical examples are Hot Join processing which requires taking the bus lock in maintenance, which in turn, can only be done from a sleep-able context

Description

A `struct i3c_master_controller` has to be registered to the I3C subsystem through `i3c_master_register()`. None of `struct i3c_master_controller` fields should be set manually, just pass appropriate values to `i3c_master_register()`.

i3c_bus_for_each_i2cdev(bus, dev)
iterate over all I2C devices present on the bus

Parameters

bus the I3C bus

dev an I2C device descriptor pointer updated to point to the current slot at each iteration of the loop

Description

Iterate over all I2C devs present on the bus.

i3c_bus_for_each_i3cdev(bus, dev)
iterate over all I3C devices present on the bus

Parameters

bus the I3C bus

dev and I3C device descriptor pointer updated to point to the current slot at each iteration of the loop

Description

Iterate over all I3C devs present on the bus.

void * **i3c_dev_get_master_data**(const struct i3c_dev_desc * dev)
get master private data attached to an I3C device descriptor

Parameters

const struct i3c_dev_desc * dev the I3C device descriptor to get private data from

Return

the private data previously attached with i3c_dev_set_master_data() or NULL if no data has been attached to the device.

void **i3c_dev_set_master_data**(struct i3c_dev_desc * dev, void * data)
attach master private data to an I3C device descriptor

Parameters

struct i3c_dev_desc * dev the I3C device descriptor to attach private data to

void * data private data

Description

This functions allows a master controller to attach per-device private data which can then be retrieved with `i3c_dev_get_master_data()`.

void * **i2c_dev_get_master_data**(const struct i2c_dev_desc * dev)
get master private data attached to an I2C device descriptor

Parameters

const struct i2c_dev_desc * dev the I2C device descriptor to get private data from

Return

the private data previously attached with i2c_dev_set_master_data() or NULL if no data has been attached to the device.

void **i2c_dev_set_master_data**(struct i2c_dev_desc * dev, void * data)
attach master private data to an I2C device descriptor

Parameters

struct i2c_dev_desc * dev the I2C device descriptor to attach private data to

void * data private data

Description

This functions allows a master controller to attach per-device private data which can then be retrieved with i2c_device_get_master_data().

struct i3c_master_controller * **i3c_dev_get_master**(struct i3c_dev_desc * dev)
get master used to communicate with a device

Parameters

struct i3c_dev_desc * dev I3C dev

Return

the master controller driving **dev**

struct i3c_master_controller * **i2c_dev_get_master**(struct i2c_dev_desc * dev)
get master used to communicate with a device

Parameters

struct i2c_dev_desc * dev I2C dev

Return

the master controller driving **dev**

struct i3c_bus * **i3c_master_get_bus**(struct i3c_master_controller * master)
get the bus attached to a master

Parameters

struct i3c_master_controller * master master object

Return

the I3C bus **master** is connected to

CHAPTER

TWENTYEIGHT

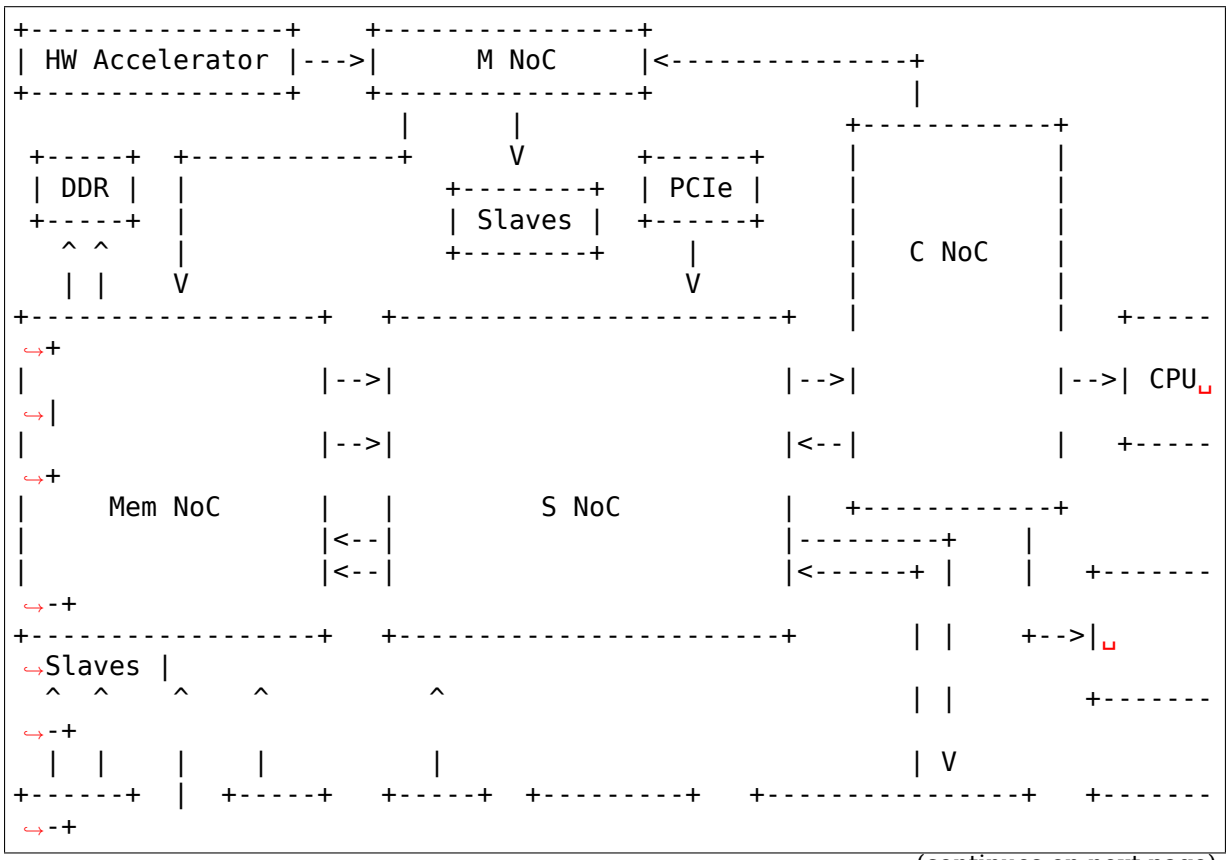
GENERIC SYSTEM INTERCONNECT SUBSYSTEM

28.1 Introduction

This framework is designed to provide a standard kernel interface to control the settings of the interconnects on an SoC. These settings can be throughput, latency and priority between multiple interconnected devices or functional blocks. This can be controlled dynamically in order to save power or provide maximum performance.

The interconnect bus is hardware with configurable parameters, which can be set on a data path according to the requests received from various drivers. An example of interconnect buses are the interconnects between various components or functional blocks in chipsets. There can be multiple interconnects on an SoC that can be multi-tiered.

Below is a simplified diagram of a real-world SoC interconnect bus topology.



(continues on next page)

(continued from previous page)

```
| CPUs |  |  | GPU |   | DSP |  | Masters |-->|       P NoC    |-->|␣
↪Slaves |
+------+  |  +-----+   +-----+  +---------+   +----------------+   +-------
↪-+
          |
      +-------+
      | Modem |
      +-------+
```

28.2 Terminology

Interconnect provider is the software definition of the interconnect hardware. The interconnect providers on the above diagram are M NoC, S NoC, C NoC, P NoC and Mem NoC.

Interconnect node is the software definition of the interconnect hardware port. Each interconnect provider consists of multiple interconnect nodes, which are connected to other SoC components including other interconnect providers. The point on the diagram where the CPUs connect to the memory is called an interconnect node, which belongs to the Mem NoC interconnect provider.

Interconnect endpoints are the first or the last element of the path. Every endpoint is a node, but not every node is an endpoint.

Interconnect path is everything between two endpoints including all the nodes that have to be traversed to reach from a source to destination node. It may include multiple master-slave pairs across several interconnect providers.

Interconnect consumers are the entities which make use of the data paths exposed by the providers. The consumers send requests to providers requesting various throughput, latency and priority. Usually the consumers are device drivers, that send request based on their needs. An example for a consumer is a video decoder that supports various formats and image sizes.

28.3 Interconnect providers

Interconnect provider is an entity that implements methods to initialize and configure interconnect bus hardware. The interconnect provider drivers should be registered with the interconnect provider core.

struct **icc_onecell_data**
driver data for onecell interconnect providers

Definition

```
struct icc_onecell_data {
  unsigned int num_nodes;
  struct icc_node *nodes[];
};
```

Members

num_nodes number of nodes in this device

nodes array of pointers to the nodes in this device

struct **icc_provider**
interconnect provider (controller) entity that might provide multiple interconnect controls

Definition

```
struct icc_provider {
  struct list_head        provider_list;
  struct list_head        nodes;
  int (*set)(struct icc_node *src, struct icc_node *dst);
  int (*aggregate)(struct icc_node *node, u32 tag, u32 avg_bw, u32 peak_bw,
↪ u32 *agg_avg, u32 *agg_peak);
  void (*pre_aggregate)(struct icc_node *node);
  struct icc_node* (*xlate)(struct of_phandle_args *spec, void *data);
  struct device           *dev;
  int users;
  void *data;
};
```

Members

provider_list list of the registered interconnect providers

nodes internal list of the interconnect provider nodes

set pointer to device specific set operation function

aggregate pointer to device specific aggregate operation function

pre_aggregate pointer to device specific function that is called before the aggregation begins (optional)

xlate provider-specific callback for mapping nodes from phandle arguments

dev the device this interconnect provider belongs to

users count of active users

data pointer to private data

struct **icc_node**
entity that is part of the interconnect topology

Definition

```
struct icc_node {
  int id;
  const char              *name;
  struct icc_node         **links;
  size_t num_links;
  struct icc_provider     *provider;
  struct list_head        node_list;
  struct list_head        search_list;
  struct icc_node         *reverse;
  u8 is_traversed:1;
  struct hlist_head       req_list;
  u32 avg_bw;
```

(continues on next page)

(continued from previous page)

```
  u32 peak_bw;
  void *data;
};
```

Members

id platform specific node id

name node name used in debugfs

links a list of targets pointing to where we can go next when traversing

num_links number of links to other interconnect nodes

provider points to the interconnect provider of this node

node_list the list entry in the parent provider's "nodes" list

search_list list used when walking the nodes graph

reverse pointer to previous node when walking the nodes graph

is_traversed flag that is used when walking the nodes graph

req_list a list of QoS constraint requests associated with this node

avg_bw aggregated value of average bandwidth requests from all consumers

peak_bw aggregated value of peak bandwidth requests from all consumers

data pointer to private data

28.4 Interconnect consumers

Interconnect consumers are the clients which use the interconnect APIs to get paths between endpoints and set their bandwidth/latency/QoS requirements for these interconnect paths. These interfaces are not currently documented.

28.5 Interconnect debugfs interfaces

Like several other subsystems interconnect will create some files for debugging and introspection. Files in debugfs are not considered ABI so application software shouldn't rely on format details change between kernel versions.

`/sys/kernel/debug/interconnect/interconnect_summary`:

Show all interconnect nodes in the system with their aggregated bandwidth request. Indented under each node show bandwidth requests from each device.

`/sys/kernel/debug/interconnect/interconnect_graph`:

Show the interconnect graph in the graphviz dot format. It shows all interconnect nodes and links in the system and groups together nodes from the same provider as subgraphs. The format is human-readable and can also be piped through dot to generate diagrams in many graphical formats:

```
$ cat /sys/kernel/debug/interconnect/interconnect_graph | \
        dot -Tsvg > interconnect_graph.svg
```

CHAPTER

TWENTYNINE

DEVICE FREQUENCY SCALING

29.1 Introduction

This framework provides a standard kernel interface for Dynamic Voltage and Frequency Switching on arbitrary devices.

It exposes controls for adjusting frequency through sysfs files which are similar to the cpufreq subsystem.

Devices for which current usage can be measured can have their frequency automatically adjusted by governors.

29.2 API

Device drivers need to initialize a `devfreq_profile` and call the `devfreq_add_device()` function to create a `devfreq` instance.

struct **devfreq_dev_status**
: Data given from devfreq user device to governors. Represents the performance statistics.

Definition

```
struct devfreq_dev_status {
  unsigned long total_time;
  unsigned long busy_time;
  unsigned long current_frequency;
  void *private_data;
};
```

Members

total_time The total time represented by this instance of devfreq_dev_status

busy_time The time that the device was working among the total_time.

current_frequency The operating frequency.

private_data An entry not specified by the devfreq framework. A device and a specific governor may have their own protocol with private_data. However, because this is governor-specific, a governor using this will be only compatible with devices aware of it.

struct **devfreq_dev_profile**
Devfreq's user device profile

Definition

```
struct devfreq_dev_profile {
  unsigned long initial_freq;
  unsigned int polling_ms;
  int (*target)(struct device *dev, unsigned long *freq, u32 flags);
  int (*get_dev_status)(struct device *dev, struct devfreq_dev_status␣
↪*stat);
  int (*get_cur_freq)(struct device *dev, unsigned long *freq);
  void (*exit)(struct device *dev);
  unsigned long *freq_table;
  unsigned int max_state;
};
```

Members

initial_freq The operating frequency when `devfreq_add_device()` is called.

polling_ms The polling interval in ms. 0 disables polling.

target The device should set its operating frequency at freq or lowest-upper-than-freq value. If freq is higher than any operable frequency, set maximum. Before returning, target function should set freq at the current frequency. The "flags" parameter's possible values are explained above with "DEVFREQ_FLAG_*" macros.

get_dev_status The device should provide the current performance status to devfreq. Governors are recommended not to use this directly. Instead, governors are recommended to use devfreq_update_stats() along with devfreq.last_status.

get_cur_freq The device should provide the current frequency at which it is operating.

exit An optional callback that is called when devfreq is removing the devfreq object due to error or from `devfreq_remove_device()` call. If the user has registered devfreq->nb at a notifier-head, this is the time to unregister it.

freq_table Optional list of frequencies to support statistics and freq_table must be generated in ascending order.

max_state The size of freq_table.

struct **devfreq_stats**
Statistics of devfreq device behavior

Definition

```
struct devfreq_stats {
  unsigned int total_trans;
  unsigned int *trans_table;
  u64 *time_in_state;
  u64 last_update;
};
```

Members

total_trans Number of devfreq transitions.

trans_table Statistics of devfreq transitions.

time_in_state Statistics of devfreq states.

last_update The last time stats were updated.

struct **devfreq**
Device devfreq structure

Definition

```
struct devfreq {
  struct list_head node;
  struct mutex lock;
  struct device dev;
  struct devfreq_dev_profile *profile;
  const struct devfreq_governor *governor;
  char governor_name[DEVFREQ_NAME_LEN];
  struct notifier_block nb;
  struct delayed_work work;
  unsigned long previous_freq;
  struct devfreq_dev_status last_status;
  void *data;
  struct dev_pm_qos_request user_min_freq_req;
  struct dev_pm_qos_request user_max_freq_req;
  unsigned long scaling_min_freq;
  unsigned long scaling_max_freq;
  bool stop_polling;
  unsigned long suspend_freq;
  unsigned long resume_freq;
  atomic_t suspend_count;
  struct devfreq_stats stats;
  struct srcu_notifier_head transition_notifier_list;
  struct notifier_block nb_min;
  struct notifier_block nb_max;
};
```

Members

node list node - contains the devices with devfreq that have been registered.

lock a mutex to protect accessing devfreq.

dev device registered by devfreq class. dev.parent is the device using devfreq.

profile device-specific devfreq profile

governor method how to choose frequency based on the usage.

governor_name devfreq governor name for use with this devfreq

nb notifier block used to notify devfreq object that it should reevaluate operable frequencies. Devfreq users may use devfreq.nb to the corresponding register notifier call chain.

work delayed work for load monitoring.

previous_freq previously configured frequency value.

last_status devfreq user device info, performance statistics

data Private data of the governor. The devfreq framework does not touch this.

user_min_freq_req PM QoS minimum frequency request from user (via sysfs)

user_max_freq_req PM QoS maximum frequency request from user (via sysfs)

scaling_min_freq Limit minimum frequency requested by OPP interface

scaling_max_freq Limit maximum frequency requested by OPP interface

stop_polling devfreq polling status of a device.

suspend_freq frequency of a device set during suspend phase.

resume_freq frequency of a device set in resume phase.

suspend_count suspend requests counter for a device.

stats Statistics of devfreq device behavior

transition_notifier_list list head of DEVFREQ_TRANSITION_NOTIFIER notifier

nb_min Notifier block for DEV_PM_QOS_MIN_FREQUENCY

nb_max Notifier block for DEV_PM_QOS_MAX_FREQUENCY

Description

This structure stores the devfreq information for a given device.

Note that when a governor accesses entries in struct devfreq in its functions except for the context of callbacks defined in struct devfreq_governor, the governor should protect its access with the struct mutex lock in struct devfreq. A governor may use this mutex to protect its own private data in `void *data` as well.

int **update_devfreq**(struct devfreq * devfreq)
Reevaluate the device and configure frequency

Parameters

struct devfreq * devfreq the devfreq device

Note

devfreq->lock must be held

struct **devfreq_simple_ondemand_data**
`void *data` fed to struct devfreq and devfreq_add_device

Definition

```
struct devfreq_simple_ondemand_data {
  unsigned int upthreshold;
  unsigned int downdifferential;
};
```

Members

upthreshold If the load is over this value, the frequency jumps. Specify 0 to use the default. Valid value = 0 to 100.

downdifferential If the load is under upthreshold - downdifferential, the governor may consider slowing the frequency down. Specify 0 to use the default. Valid value = 0 to 100. downdifferential < upthreshold must hold.

Description

If the fed devfreq_simple_ondemand_data pointer is NULL to the governor, the governor uses the default values.

struct **devfreq_passive_data**
`void *data` fed to struct devfreq and devfreq_add_device

Definition

```
struct devfreq_passive_data {
  struct devfreq *parent;
  int (*get_target_freq)(struct devfreq *this, unsigned long *freq);
  struct devfreq *this;
  struct notifier_block nb;
};
```

Members

parent the devfreq instance of parent device.

get_target_freq Optional callback, Returns desired operating frequency for the device using passive governor. That is called when passive governor should decide the next frequency by using the new frequency of parent devfreq device using governors except for passive governor. If the devfreq device has the specific method to decide the next frequency, should use this callback.

this the devfreq instance of own device.

nb the notifier block for DEVFREQ_TRANSITION_NOTIFIER list

Description

The devfreq_passive_data have to set the devfreq instance of parent device with governors except for the passive governor. But, don't need to initialize the 'this' and 'nb' field because the devfreq core will handle them.

struct **devfreq_event_dev**
the devfreq-event device

Definition

```
struct devfreq_event_dev {
  struct list_head node;
  struct device dev;
  struct mutex lock;
  u32 enable_count;
  const struct devfreq_event_desc *desc;
};
```

Members

node Contain the devfreq-event device that have been registered.

dev the device registered by devfreq-event class. dev.parent is the device using devfreq-event.

lock a mutex to protect accessing devfreq-event.

enable_count the number of enable function have been called.

desc the description for devfreq-event device.

Description

This structure contains devfreq-event device information.

struct **devfreq_event_data**
the devfreq-event data

Definition

```
struct devfreq_event_data {
  unsigned long load_count;
  unsigned long total_count;
};
```

Members

load_count load count of devfreq-event device for the given period.

total_count total count of devfreq-event device for the given period. each count may represent a clock cycle, a time unit (ns/us/…), or anything the device driver wants. Generally, utilization is load_count / total_count.

Description

This structure contains the data of devfreq-event device for polling period.

struct **devfreq_event_ops**
the operations of devfreq-event device

Definition

```
struct devfreq_event_ops {
  int (*enable)(struct devfreq_event_dev *edev);
  int (*disable)(struct devfreq_event_dev *edev);
  int (*reset)(struct devfreq_event_dev *edev);
  int (*set_event)(struct devfreq_event_dev *edev);
  int (*get_event)(struct devfreq_event_dev *edev, struct devfreq_event_
↪data *edata);
};
```

Members

enable Enable the devfreq-event device.

disable Disable the devfreq-event device.

reset Reset all setting of the devfreq-event device.

set_event Set the specific event type for the devfreq-event device.

get_event Get the result of the devfreq-event devie with specific event type.

Description

This structure contains devfreq-event device operations which can be implemented by devfreq-event device drivers.

struct **devfreq_event_desc**
the descriptor of devfreq-event device

Definition

```
struct devfreq_event_desc {
  const char *name;
  u32 event_type;
  void *driver_data;
  const struct devfreq_event_ops *ops;
};
```

Members

name the name of devfreq-event device.

event_type the type of the event determined and used by driver

driver_data the private data for devfreq-event driver.

ops the operation to control devfreq-event device.

Description

Each devfreq-event device is described with a this structure. This structure contains the various data for devfreq-event device. The event_type describes what is going to be counted in the register. It might choose to count e.g. read requests, write data in bytes, etc. The full supported list of types is present in specyfic header in: include/dt-bindings/pmu/.

int **devfreq_update_status**(struct devfreq * devfreq, unsigned long freq)
Update statistics of devfreq behavior

Parameters

struct devfreq * devfreq the devfreq instance

unsigned long freq the update target frequency

int **update_devfreq**(struct devfreq * devfreq)
Reevaluate the device and configure frequency.

Parameters

struct devfreq * devfreq the devfreq instance.

Note

Lock devfreq->lock before calling update_devfreq This function is exported for governors.

void **devfreq_monitor_start**(struct devfreq * devfreq)
Start load monitoring of devfreq instance

Parameters

struct devfreq * devfreq the devfreq instance.

Description

Helper function for starting devfreq device load monitoring. By default delayed work based monitoring is supported. Function to be called from governor in re-

sponse to DEVFREQ_GOV_START event when device is added to devfreq framework.

void **devfreq_monitor_stop**(struct devfreq * devfreq)
Stop load monitoring of a devfreq instance

Parameters

struct devfreq * devfreq the devfreq instance.

Description

Helper function to stop devfreq device load monitoring. Function to be called from governor in response to DEVFREQ_GOV_STOP event when device is removed from devfreq framework.

void **devfreq_monitor_suspend**(struct devfreq * devfreq)
Suspend load monitoring of a devfreq instance

Parameters

struct devfreq * devfreq the devfreq instance.

Description

Helper function to suspend devfreq device load monitoring. Function to be called from governor in response to DEVFREQ_GOV_SUSPEND event or when polling interval is set to zero.

Note

Though this function is same as `devfreq_monitor_stop()`, intentionally kept separate to provide hooks for collecting transition statistics.

void **devfreq_monitor_resume**(struct devfreq * devfreq)
Resume load monitoring of a devfreq instance

Parameters

struct devfreq * devfreq the devfreq instance.

Description

Helper function to resume devfreq device load monitoring. Function to be called from governor in response to DEVFREQ_GOV_RESUME event or when polling interval is set to non-zero.

void **devfreq_update_interval**(struct devfreq * devfreq, unsigned int * delay)
Update device devfreq monitoring interval

Parameters

struct devfreq * devfreq the devfreq instance.

unsigned int * delay new polling interval to be set.

Description

Helper function to set new load monitoring polling interval. Function to be called from governor in response to DEVFREQ_GOV_UPDATE_INTERVAL event.

struct devfreq * **devfreq_add_device**(struct device * dev, struct devfreq_dev_profile * profile, const char * governor_name, void * data)
Add devfreq feature to the device

Parameters

struct device * dev the device to add devfreq feature.

struct devfreq_dev_profile * profile device-specific profile to run devfreq.

const char * governor_name name of the policy to choose frequency.

void * data private data for the governor. The devfreq framework does not touch this value.

int **devfreq_remove_device**(struct devfreq * devfreq)
Remove devfreq feature from a device.

Parameters

struct devfreq * devfreq the devfreq instance to be removed

Description

The opposite of `devfreq_add_device()`.

struct devfreq * **devm_devfreq_add_device**(struct device * dev, struct devfreq_dev_profile * profile, const char * governor_name, void * data)
Resource-managed `devfreq_add_device()`

Parameters

struct device * dev the device to add devfreq feature.

struct devfreq_dev_profile * profile device-specific profile to run devfreq.

const char * governor_name name of the policy to choose frequency.

void * data private data for the governor. The devfreq framework does not touch this value.

Description

This function manages automatically the memory of devfreq device using device resource management and simplify the free operation for memory of devfreq device.

void **devm_devfreq_remove_device**(struct device * dev, struct devfreq * devfreq)
Resource-managed `devfreq_remove_device()`

Parameters

struct device * dev the device from which to remove devfreq feature.

struct devfreq * devfreq the devfreq instance to be removed

int **devfreq_suspend_device**(struct devfreq * devfreq)
Suspend devfreq of a device.

Parameters

struct devfreq * devfreq the devfreq instance to be suspended

Description

This function is intended to be called by the pm callbacks (e.g., runtime_suspend, suspend) of the device driver that holds the devfreq.

int **devfreq_resume_device**(struct devfreq * devfreq)
Resume devfreq of a device.

Parameters

struct devfreq * devfreq the devfreq instance to be resumed

Description

This function is intended to be called by the pm callbacks (e.g., runtime_resume, resume) of the device driver that holds the devfreq.

int **devfreq_add_governor**(struct devfreq_governor * governor)
Add devfreq governor

Parameters

struct devfreq_governor * governor the devfreq governor to be added

int **devfreq_remove_governor**(struct devfreq_governor * governor)
Remove devfreq feature from a device.

Parameters

struct devfreq_governor * governor the devfreq governor to be removed

struct dev_pm_opp * **devfreq_recommended_opp**(struct device * dev, unsigned long * freq, u32 flags)
Helper function to get proper OPP for the freq value given to target callback.

Parameters

struct device * dev The devfreq user device. (parent of devfreq)

unsigned long * freq The frequency given to target function

u32 flags Flags handed from devfreq framework.

Description

The callers are required to call dev_pm_opp_put() for the returned OPP after use.

int **devfreq_register_opp_notifier**(struct device * dev, struct devfreq * devfreq)
Helper function to get devfreq notified for any changes in the OPP availability changes

Parameters

struct device * dev The devfreq user device. (parent of devfreq)

struct devfreq * devfreq The devfreq object.

int **devfreq_unregister_opp_notifier**(struct device * dev, struct devfreq * devfreq)

Helper function to stop getting devfreq notified for any changes in the OPP availability changes anymore.

Parameters

struct device * dev The devfreq user device. (parent of devfreq)

struct devfreq * devfreq The devfreq object.

Description

At exit() callback of devfreq_dev_profile, this must be included if devfreq_recommended_opp is used.

int **devm_devfreq_register_opp_notifier**(struct device * dev, struct devfreq * devfreq)

Resource-managed `devfreq_register_opp_notifier()`

Parameters

struct device * dev The devfreq user device. (parent of devfreq)

struct devfreq * devfreq The devfreq object.

void **devm_devfreq_unregister_opp_notifier**(struct device * dev, struct devfreq * devfreq)

Resource-managed `devfreq_unregister_opp_notifier()`

Parameters

struct device * dev The devfreq user device. (parent of devfreq)

struct devfreq * devfreq The devfreq object.

int **devfreq_register_notifier**(struct devfreq * devfreq, struct notifier_block * nb, unsigned int list)

Register a driver with devfreq

Parameters

struct devfreq * devfreq The devfreq object.

struct notifier_block * nb The notifier block to register.

unsigned int list DEVFREQ_TRANSITION_NOTIFIER.

int **devm_devfreq_register_notifier**(struct device * dev, struct devfreq * devfreq, struct notifier_block * nb, unsigned int list)

Parameters

struct device * dev The devfreq user device. (parent of devfreq)

struct devfreq * devfreq The devfreq object.

struct notifier_block * nb The notifier block to be unregistered.

unsigned int list DEVFREQ_TRANSITION_NOTIFIER.

Description

- Resource-managed `devfreq_register_notifier()`

void **devm_devfreq_unregister_notifier**(struct device * dev, struct devfreq * devfreq, struct notifier_block * nb, unsigned int list)

Parameters

struct device * dev The devfreq user device. (parent of devfreq)

struct devfreq * devfreq The devfreq object.

struct notifier_block * nb The notifier block to be unregistered.

unsigned int list DEVFREQ_TRANSITION_NOTIFIER.

Description

- Resource-managed devfreq_unregister_notifier()

int **devfreq_event_enable_edev**(struct devfreq_event_dev * edev)
Enable the devfreq-event dev and increase the enable_count of devfreq-event dev.

Parameters

struct devfreq_event_dev * edev the devfreq-event device

Description

Note that this function increase the enable_count and enable the devfreq-event device. The devfreq-event device should be enabled before using it by devfreq device.

int **devfreq_event_disable_edev**(struct devfreq_event_dev * edev)
Disable the devfreq-event dev and decrease the enable_count of the devfreq-event dev.

Parameters

struct devfreq_event_dev * edev the devfreq-event device

Description

Note that this function decrease the enable_count and disable the devfreq-event device. After the devfreq-event device is disabled, devfreq device can't use the devfreq-event device for get/set/reset operations.

bool **devfreq_event_is_enabled**(struct devfreq_event_dev * edev)
Check whether devfreq-event dev is enabled or not.

Parameters

struct devfreq_event_dev * edev the devfreq-event device

Description

Note that this function check whether devfreq-event dev is enabled or not. If return true, the devfreq-event dev is enabeld. If return false, the devfreq-event dev is disabled.

int **devfreq_event_set_event**(struct devfreq_event_dev * edev)
Set event to devfreq-event dev to start.

Parameters

struct devfreq_event_dev * edev the devfreq-event device

Description

Note that this function set the event to the devfreq-event device to start for getting the event data which could be various event type.

int **devfreq_event_get_event**(struct devfreq_event_dev * edev, struct devfreq_event_data * edata)
Get {load|total}_count from devfreq-event dev.

Parameters

struct devfreq_event_dev * edev the devfreq-event device

struct devfreq_event_data * edata the calculated data of devfreq-event device

Description

Note that this function get the calculated event data from devfreq-event dev after stoping the progress of whole sequence of devfreq-event dev.

int **devfreq_event_reset_event**(struct devfreq_event_dev * edev)
Reset all opeations of devfreq-event dev.

Parameters

struct devfreq_event_dev * edev the devfreq-event device

Description

Note that this function stop all operations of devfreq-event dev and reset the current event data to make the devfreq-event device into initial state.

struct devfreq_event_dev * **devfreq_event_get_edev_by_phandle**(struct device * dev, int index)
Get the devfreq-event dev from devicetree.

Parameters

struct device * dev the pointer to the given device

int index the index into list of devfreq-event device

Description

Note that this function return the pointer of devfreq-event device.

int **devfreq_event_get_edev_count**(struct device * dev)
Get the count of devfreq-event dev

Parameters

struct device * dev the pointer to the given device

Description

Note that this function return the count of devfreq-event devices.

struct devfreq_event_dev * **devfreq_event_add_edev**(struct device * dev, struct devfreq_event_desc * desc)
Add new devfreq-event device.

Parameters

struct device * dev the device owning the devfreq-event device being created

struct devfreq_event_desc * desc the devfreq-event device's decriptor which include essential data for devfreq-event device.

Description

Note that this function add new devfreq-event device to devfreq-event class list and register the device of the devfreq-event device.

int **devfreq_event_remove_edev**(struct devfreq_event_dev * edev)
Remove the devfreq-event device registered.

Parameters

struct devfreq_event_dev * edev the devfreq-event device

Description

Note that this function removes the registered devfreq-event device.

struct devfreq_event_dev * **devm_devfreq_event_add_edev**(struct device * dev, struct devfreq_event_desc * desc)
Resource-managed `devfreq_event_add_edev()`

Parameters

struct device * dev the device owning the devfreq-event device being created

struct devfreq_event_desc * desc the devfreq-event device's decriptor which include essential data for devfreq-event device.

Description

Note that this function manages automatically the memory of devfreq-event device using device resource management and simplify the free operation for memory of devfreq-event device.

void **devm_devfreq_event_remove_edev**(struct device * dev, struct devfreq_event_dev * edev)
Resource-managed `devfreq_event_remove_edev()`

Parameters

struct device * dev the device owning the devfreq-event device being created

struct devfreq_event_dev * edev the devfreq-event device

Description

Note that this function manages automatically the memory of devfreq-event device using device resource management.

CHAPTER

THIRTY

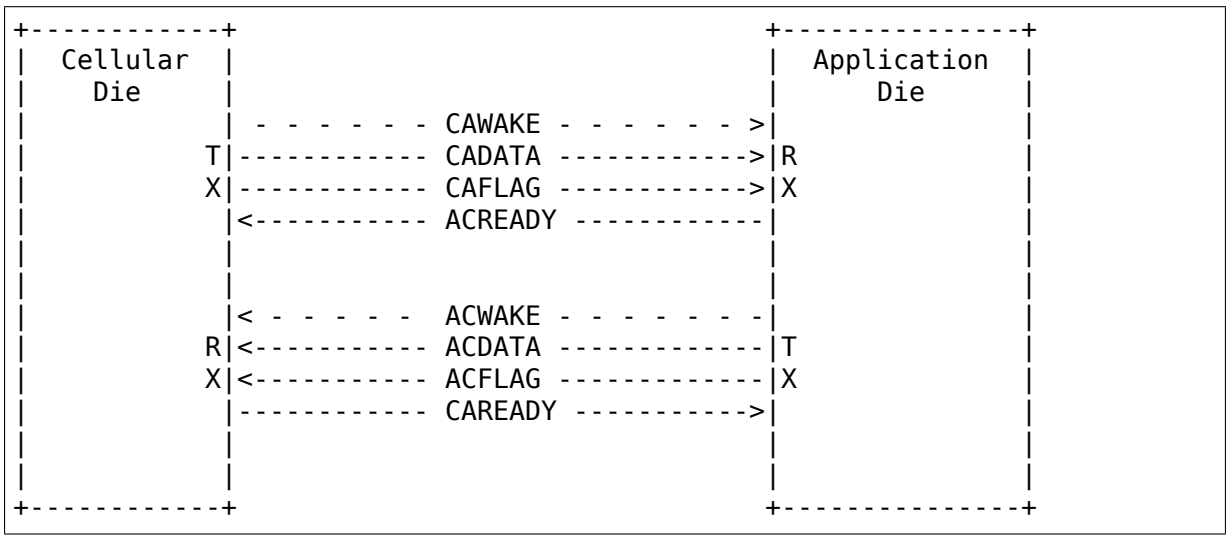
HIGH SPEED SYNCHRONOUS SERIAL INTERFACE (HSI)

30.1 Introduction

High Speed Syncronous Interface (HSI) is a fullduplex, low latency protocol, that is optimized for die-level interconnect between an Application Processor and a Baseband chipset. It has been specified by the MIPI alliance in 2003 and implemented by multiple vendors since then.

The HSI interface supports full duplex communication over multiple channels (typically 8) and is capable of reaching speeds up to 200 Mbit/s.

The serial protocol uses two signals, DATA and FLAG as combined data and clock signals and an additional READY signal for flow control. An additional WAKE signal can be used to wakeup the chips from standby modes. The signals are commonly prefixed by AC for signals going from the application die to the cellular die and CA for signals going the other way around.



30.2 HSI Subsystem in Linux

In the Linux kernel the hsi subsystem is supposed to be used for HSI devices. The hsi subsystem contains drivers for hsi controllers including support for multi-port controllers and provides a generic API for using the HSI ports.

It also contains HSI client drivers, which make use of the generic API to implement a protocol used on the HSI interface. These client drivers can use an arbitrary number of channels.

30.3 hsi-char Device

Each port automatically registers a generic client driver called hsi_char, which provides a charecter device for userspace representing the HSI port. It can be used to communicate via HSI from userspace. Userspace may configure the hsi_char device using the following ioctl commands:

HSC_RESET flush the HSI port

HSC_SET_PM enable or disable the client.

HSC_SEND_BREAK send break

HSC_SET_RX set RX configuration

HSC_GET_RX get RX configuration

HSC_SET_TX set TX configuration

HSC_GET_TX get TX configuration

30.4 The kernel HSI API

struct **hsi_channel**
    channel resource used by the hsi clients

Definition

```
struct hsi_channel {
  unsigned int    id;
  const char      *name;
};
```

Members

id Channel number

name Channel name

struct **hsi_config**
    Configuration for RX/TX HSI modules

Definition

```
struct hsi_config {
  unsigned int            mode;
  struct hsi_channel      *channels;
  unsigned int            num_channels;
  unsigned int            num_hw_channels;
  unsigned int            speed;
  union {
    unsigned int    flow;
    unsigned int    arb_mode;
  };
};
```

Members

mode Bit transmission mode (STREAM or FRAME)

channels Channel resources used by the client

num_channels Number of channel resources

num_hw_channels Number of channels the transceiver is configured for [1..16]

speed Max bit transmission speed (Kbit/s)

{unnamed_union} anonymous

flow RX flow type (SYNCHRONIZED or PIPELINE)

arb_mode Arbitration mode for TX frame (Round robin, priority)

struct **hsi_board_info**
HSI client board info

Definition

```
struct hsi_board_info {
  const char              *name;
  unsigned int            hsi_id;
  unsigned int            port;
  struct hsi_config       tx_cfg;
  struct hsi_config       rx_cfg;
  void *platform_data;
  struct dev_archdata     *archdata;
};
```

Members

name Name for the HSI device

hsi_id HSI controller id where the client sits

port Port number in the controller where the client sits

tx_cfg HSI TX configuration

rx_cfg HSI RX configuration

platform_data Platform related data

archdata Architecture-dependent device data

struct **hsi_client**
HSI client attached to an HSI port

Definition

```
struct hsi_client {
  struct device           device;
  struct hsi_config       tx_cfg;
  struct hsi_config       rx_cfg;
};
```

Members

device Driver model representation of the device

tx_cfg HSI TX configuration

rx_cfg HSI RX configuration

struct **hsi_client_driver**
Driver associated to an HSI client

Definition

```
struct hsi_client_driver {
  struct device_driver    driver;
};
```

Members

driver Driver model representation of the driver

struct **hsi_msg**
HSI message descriptor

Definition

```
struct hsi_msg {
  struct list_head        link;
  struct hsi_client       *cl;
  struct sg_table         sgt;
  void *context;
  void (*complete)(struct hsi_msg *msg);
  void (*destructor)(struct hsi_msg *msg);
  int status;
  unsigned int            actual_len;
  unsigned int            channel;
  unsigned int            ttype:1;
  unsigned int            break_frame:1;
};
```

Members

link Free to use by the current descriptor owner

cl HSI device client that issues the transfer

sgt Head of the scatterlist array

context Client context data associated to the transfer

complete Transfer completion callback

destructor Destructor to free resources when flushing

status Status of the transfer when completed

actual_len Actual length of data transferred on completion

channel Channel were to TX/RX the message

ttype Transfer type (TX if set, RX otherwise)

break_frame if true HSI will send/receive a break frame. Data buffers are ignored in the request.

struct **hsi_port**
HSI port device

Definition

```
struct hsi_port {
  struct device                 device;
  struct hsi_config             tx_cfg;
  struct hsi_config             rx_cfg;
  unsigned int                  num;
  unsigned int                  shared:1;
  int claimed;
  struct mutex                  lock;
  int (*async)(struct hsi_msg *msg);
  int (*setup)(struct hsi_client *cl);
  int (*flush)(struct hsi_client *cl);
  int (*start_tx)(struct hsi_client *cl);
  int (*stop_tx)(struct hsi_client *cl);
  int (*release)(struct hsi_client *cl);
  struct blocking_notifier_head   n_head;
};
```

Members

device Driver model representation of the device

tx_cfg Current TX path configuration

rx_cfg Current RX path configuration

num Port number

shared Set when port can be shared by different clients

claimed Reference count of clients which claimed the port

lock Serialize port claim

async Asynchronous transfer callback

setup Callback to set the HSI client configuration

flush Callback to clean the HW state and destroy all pending transfers

start_tx Callback to inform that a client wants to TX data

stop_tx Callback to inform that a client no longer wishes to TX data

release Callback to inform that a client no longer uses the port

n_head Notifier chain for signaling port events to the clients.

struct **hsi_controller**
HSI controller device

Definition

```
struct hsi_controller {
  struct device           device;
  struct module           *owner;
  unsigned int            id;
  unsigned int            num_ports;
  struct hsi_port         **port;
};
```

Members

device Driver model representation of the device

owner Pointer to the module owning the controller

id HSI controller ID

num_ports Number of ports in the HSI controller

port Array of HSI ports

unsigned int **hsi_id**(struct hsi_client * cl)
Get HSI controller ID associated to a client

Parameters

struct hsi_client * cl Pointer to a HSI client

Description

Return the controller id where the client is attached to

unsigned int **hsi_port_id**(struct hsi_client * cl)
Gets the port number a client is attached to

Parameters

struct hsi_client * cl Pointer to HSI client

Description

Return the port number associated to the client

int **hsi_setup**(struct hsi_client * cl)
Configure the client' s port

Parameters

struct hsi_client * cl Pointer to the HSI client

Description

When sharing ports, clients should either relay on a single client setup or have the same setup for all of them.

Return -errno on failure, 0 on success

int **hsi_flush**(struct hsi_client * cl)
Flush all pending transactions on the client's port

Parameters

struct hsi_client * cl Pointer to the HSI client

Description

This function will destroy all pending hsi_msg in the port and reset the HW port so it is ready to receive and transmit from a clean state.

Return -errno on failure, 0 on success

int **hsi_async_read**(struct hsi_client * cl, struct hsi_msg * msg)
Submit a read transfer

Parameters

struct hsi_client * cl Pointer to the HSI client

struct hsi_msg * msg HSI message descriptor of the transfer

Description

Return -errno on failure, 0 on success

int **hsi_async_write**(struct hsi_client * cl, struct hsi_msg * msg)
Submit a write transfer

Parameters

struct hsi_client * cl Pointer to the HSI client

struct hsi_msg * msg HSI message descriptor of the transfer

Description

Return -errno on failure, 0 on success

int **hsi_start_tx**(struct hsi_client * cl)
Signal the port that the client wants to start a TX

Parameters

struct hsi_client * cl Pointer to the HSI client

Description

Return -errno on failure, 0 on success

int **hsi_stop_tx**(struct hsi_client * cl)
Signal the port that the client no longer wants to transmit

Parameters

struct hsi_client * cl Pointer to the HSI client

Description

Return -errno on failure, 0 on success

void **hsi_port_unregister_clients**(struct hsi_port * port)
Unregister an HSI port

Parameters

struct hsi_port * port The HSI port to unregister

void **hsi_unregister_controller**(struct hsi_controller * hsi)
Unregister an HSI controller

Parameters

struct hsi_controller * hsi The HSI controller to register

int **hsi_register_controller**(struct hsi_controller * hsi)
Register an HSI controller and its ports

Parameters

struct hsi_controller * hsi The HSI controller to register

Description

Returns -errno on failure, 0 on success.

int **hsi_register_client_driver**(struct hsi_client_driver * drv)
Register an HSI client to the HSI bus

Parameters

struct hsi_client_driver * drv HSI client driver to register

Description

Returns -errno on failure, 0 on success.

void **hsi_put_controller**(struct hsi_controller * hsi)
Free an HSI controller

Parameters

struct hsi_controller * hsi Pointer to the HSI controller to freed

Description

HSI controller drivers should only use this function if they need to free their allocated hsi_controller structures before a successful call to hsi_register_controller. Other use is not allowed.

struct hsi_controller * **hsi_alloc_controller**(unsigned int n_ports, gfp_t flags)
Allocate an HSI controller and its ports

Parameters

unsigned int n_ports Number of ports on the HSI controller

gfp_t flags Kernel allocation flags

Description

Return NULL on failure or a pointer to an hsi_controller on success.

void **hsi_free_msg**(struct hsi_msg * msg)
Free an HSI message

Parameters

struct hsi_msg * msg Pointer to the HSI message

Description

Client is responsible to free the buffers pointed by the scatterlists.

struct hsi_msg * **hsi_alloc_msg**(unsigned int nents, gfp_t flags)
Allocate an HSI message

Parameters

unsigned int nents Number of memory entries

gfp_t flags Kernel allocation flags

Description

nents can be 0. This mainly makes sense for read transfer. In that case, HSI drivers will call the complete callback when there is data to be read without consuming it.

Return NULL on failure or a pointer to an hsi_msg on success.

int **hsi_async**(struct hsi_client * cl, struct hsi_msg * msg)
Submit an HSI transfer to the controller

Parameters

struct hsi_client * cl HSI client sending the transfer

struct hsi_msg * msg The HSI transfer passed to controller

Description

The HSI message must have the channel, ttype, complete and destructor fields set beforehand. If nents > 0 then the client has to initialize also the scatterlists to point to the buffers to write to or read from.

HSI controllers relay on pre-allocated buffers from their clients and they do not allocate buffers on their own.

Once the HSI message transfer finishes, the HSI controller calls the complete callback with the status and actual_len fields of the HSI message updated. The complete callback can be called before returning from hsi_async.

Returns -errno on failure or 0 on success

int **hsi_claim_port**(struct hsi_client * cl, unsigned int share)
Claim the HSI client's port

Parameters

struct hsi_client * cl HSI client that wants to claim its port

unsigned int share Flag to indicate if the client wants to share the port or not.

Description

Returns -errno on failure, 0 on success.

void **hsi_release_port**(struct hsi_client * cl)
Release the HSI client's port

Parameters

struct hsi_client * cl HSI client which previously claimed its port

int **hsi_register_port_event**(struct hsi_client * cl, void (*handler)(struct hsi_client *, unsigned long))
Register a client to receive port events

Parameters

struct hsi_client * cl HSI client that wants to receive port events

void (*)(struct hsi_client *, unsigned long) handler Event handler callback

Description

Clients should register a callback to be able to receive events from the ports. Registration should happen after claiming the port. The handler can be called in interrupt context.

Returns -errno on error, or 0 on success.

int **hsi_unregister_port_event**(struct hsi_client * cl)
Stop receiving port events for a client

Parameters

struct hsi_client * cl HSI client that wants to stop receiving port events

Description

Clients should call this function before releasing their associated port.

Returns -errno on error, or 0 on success.

int **hsi_event**(struct hsi_port * port, unsigned long event)
Notifies clients about port events

Parameters

struct hsi_port * port Port where the event occurred

unsigned long event The event type

Description

Clients should not be concerned about wake line behavior. However, due to a race condition in HSI HW protocol, clients need to be notified about wake line changes, so they can implement a workaround for it.

Events: HSI_EVENT_START_RX - Incoming wake line high HSI_EVENT_STOP_RX - Incoming wake line down

Returns -errno on error, or 0 on success.

int **hsi_get_channel_id_by_name**(struct hsi_client * cl, char * name)
acquire channel id by channel name

Parameters

struct hsi_client * cl HSI client, which uses the channel

char * name name the channel is known under

Description

Clients can call this function to get the hsi channel ids similar to requesting IRQs or GPIOs by name. This function assumes the same channel configuration is used for RX and TX.

Returns -errno on error or channel id on success.

CHAPTER

THIRTYONE

ERROR DETECTION AND CORRECTION (EDAC) DEVICES

31.1 Main Concepts used at the EDAC subsystem

There are several things to be aware of that aren't at all obvious, like sockets, *socket sets, banks, rows, chip-select rows, channels, etc…

These are some of the many terms that are thrown about that don't always mean what people think they mean (Inconceivable!). In the interest of creating a common ground for discussion, terms and their definitions will be established.

- Memory devices

The individual DRAM chips on a memory stick. These devices commonly output 4 and 8 bits each (x4, x8). Grouping several of these in parallel provides the number of bits that the memory controller expects: typically 72 bits, in order to provide 64 bits + 8 bits of ECC data.

- Memory Stick

A printed circuit board that aggregates multiple memory devices in parallel. In general, this is the Field Replaceable Unit (FRU) which gets replaced, in the case of excessive errors. Most often it is also called DIMM (Dual Inline Memory Module).

- Memory Socket

A physical connector on the motherboard that accepts a single memory stick. Also called as "slot" on several datasheets.

- Channel

A memory controller channel, responsible to communicate with a group of DIMMs. Each channel has its own independent control (command) and data bus, and can be used independently or grouped with other channels.

- Branch

It is typically the highest hierarchy on a Fully-Buffered DIMM memory controller. Typically, it contains two channels. Two channels at the same branch can be used in single mode or in lockstep mode. When lockstep is enabled, the cacheline is doubled, but it generally brings some performance penalty. Also, it is generally not possible to point to just one memory stick when an error occurs, as the error correction code is calculated using two DIMMs instead of one. Due to that, it is capable of correcting more errors than on single mode.

- Single-channel

The data accessed by the memory controller is contained into one dimm only. E. g. if the data is 64 bits-wide, the data flows to the CPU using one 64 bits parallel access. Typically used with SDR, DDR, DDR2 and DDR3 memories. FB-DIMM and RAMBUS use a different concept for channel, so this concept doesn't apply there.

- Double-channel

The data size accessed by the memory controller is interlaced into two dimms, accessed at the same time. E. g. if the DIMM is 64 bits-wide (72 bits with ECC), the data flows to the CPU using a 128 bits parallel access.

- Chip-select row

This is the name of the DRAM signal used to select the DRAM ranks to be accessed. Common chip-select rows for single channel are 64 bits, for dual channel 128 bits. It may not be visible by the memory controller, as some DIMM types have a memory buffer that can hide direct access to it from the Memory Controller.

- Single-Ranked stick

A Single-ranked stick has 1 chip-select row of memory. Motherboards commonly drive two chip-select pins to a memory stick. A single-ranked stick, will occupy only one of those rows. The other will be unused.

- Double-Ranked stick

A double-ranked stick has two chip-select rows which access different sets of memory devices. The two rows cannot be accessed concurrently.

- Double-sided stick

DEPRECATED TERM, see Double-Ranked stick.

A double-sided stick has two chip-select rows which access different sets of memory devices. The two rows cannot be accessed concurrently. "Double-sided" is irrespective of the memory devices being mounted on both sides of the memory stick.

- Socket set

All of the memory sticks that are required for a single memory access or all of the memory sticks spanned by a chip-select row. A single socket set has two chip-select rows and if double-sided sticks are used these will occupy those chip-select rows.

- Bank

This term is avoided because it is unclear when needing to distinguish between chip-select rows and socket sets.

31.2 Memory Controllers

Most of the EDAC core is focused on doing Memory Controller error detection. The `edac_mc_alloc()`. It uses internally the struct `mem_ctl_info` to describe the memory controllers, with is an opaque struct for the EDAC drivers. Only the EDAC core is allowed to touch it.

enum **dev_type**
describe the type of memory DRAM chips used at the stick

Constants

DEV_UNKNOWN Can't be determined, or MC doesn't support detect it

DEV_X1 1 bit for data

DEV_X2 2 bits for data

DEV_X4 4 bits for data

DEV_X8 8 bits for data

DEV_X16 16 bits for data

DEV_X32 32 bits for data

DEV_X64 64 bits for data

Description

Typical values are x4 and x8.

enum **hw_event_mc_err_type**
type of the detected error

Constants

HW_EVENT_ERR_CORRECTED Corrected Error - Indicates that an ECC corrected error was detected

HW_EVENT_ERR_UNCORRECTED Uncorrected Error - Indicates an error that can't be corrected by ECC, but it is not fatal (maybe it is on an unused memory area, or the memory controller could recover from it for example, by re-trying the operation).

HW_EVENT_ERR_DEFERRED Deferred Error - Indicates an uncorrectable error whose handling is not urgent. This could be due to hardware data poisoning where the system can continue operation until the poisoned data is consumed. Preemptive measures may also be taken, e.g. offlining pages, etc.

HW_EVENT_ERR_FATAL Fatal Error - Uncorrected error that could not be recovered.

HW_EVENT_ERR_INFO Informational - The CPER spec defines a forth type of error: informational logs.

enum **mem_type**
memory types. For a more detailed reference, please see http://en.wikipedia.org/wiki/DRAM

Constants

MEM_EMPTY Empty csrow

MEM_RESERVED Reserved csrow type

MEM_UNKNOWN Unknown csrow type

MEM_FPM FPM - Fast Page Mode, used on systems up to 1995.

MEM_EDO EDO - Extended data out, used on systems up to 1998.

MEM_BEDO BEDO - Burst Extended data out, an EDO variant.

MEM_SDR SDR - Single data rate SDRAM http://en.wikipedia.org/wiki/Synchronous_dynamic_random-access_memory They use 3 pins for chip select: Pins 0 and 2 are for rank 0; pins 1 and 3 are for rank 1, if the memory is dual-rank.

MEM_RDR Registered SDR SDRAM

MEM_DDR Double data rate SDRAM http://en.wikipedia.org/wiki/DDR_SDRAM

MEM_RDDR Registered Double data rate SDRAM This is a variant of the DDR memories. A registered memory has a buffer inside it, hiding part of the memory details to the memory controller.

MEM_RMBS Rambus DRAM, used on a few Pentium III/IV controllers.

MEM_DDR2 DDR2 RAM, as described at JEDEC JESD79-2F. Those memories are labeled as "PC2-" instead of "PC" to differentiate from DDR.

MEM_FB_DDR2 Fully-Buffered DDR2, as described at JEDEC Std No. 205 and JESD206. Those memories are accessed per DIMM slot, and not by a chip select signal.

MEM_RDDR2 Registered DDR2 RAM This is a variant of the DDR2 memories.

MEM_XDR Rambus XDR It is an evolution of the original RAMBUS memories, created to compete with DDR2. Weren't used on any x86 arch, but cell_edac PPC memory controller uses it.

MEM_DDR3 DDR3 RAM

MEM_RDDR3 Registered DDR3 RAM This is a variant of the DDR3 memories.

MEM_LRDDR3 Load-Reduced DDR3 memory.

MEM_DDR4 Unbuffered DDR4 RAM

MEM_RDDR4 Registered DDR4 RAM This is a variant of the DDR4 memories.

MEM_LRDDR4 Load-Reduced DDR4 memory.

MEM_NVDIMM Non-volatile RAM

enum **edac_type**
type - Error Detection and Correction capabilities and mode

Constants

EDAC_UNKNOWN Unknown if ECC is available

EDAC_NONE Doesn't support ECC

EDAC_RESERVED Reserved ECC type

EDAC_PARITY Detects parity errors

EDAC_EC Error Checking - no correction

EDAC_SECDED Single bit error correction, Double detection

EDAC_S2ECD2ED Chipkill x2 devices - do these exist?

EDAC_S4ECD4ED Chipkill x4 devices

EDAC_S8ECD8ED Chipkill x8 devices

EDAC_S16ECD16ED Chipkill x16 devices

enum **scrub_type**
scrubbing capabilities

Constants

SCRUB_UNKNOWN Unknown if scrubber is available

SCRUB_NONE No scrubber

SCRUB_SW_PROG SW progressive (sequential) scrubbing

SCRUB_SW_SRC Software scrub only errors

SCRUB_SW_PROG_SRC Progressive software scrub from an error

SCRUB_SW_TUNABLE Software scrub frequency is tunable

SCRUB_HW_PROG HW progressive (sequential) scrubbing

SCRUB_HW_SRC Hardware scrub only errors

SCRUB_HW_PROG_SRC Progressive hardware scrub from an error

SCRUB_HW_TUNABLE Hardware scrub frequency is tunable

enum **edac_mc_layer_type**
memory controller hierarchy layer

Constants

EDAC_MC_LAYER_BRANCH memory layer is named “branch”

EDAC_MC_LAYER_CHANNEL memory layer is named “channel”

EDAC_MC_LAYER_SLOT memory layer is named “slot”

EDAC_MC_LAYER_CHIP_SELECT memory layer is named “chip select”

EDAC_MC_LAYER_ALL_MEM memory layout is unknown. All memory is mapped as a single memory area. This is used when retrieving errors from a firmware driven driver.

Description

This enum is used by the drivers to tell edac_mc_sysfs what name should be used when describing a memory stick location.

struct **edac_mc_layer**
describes the memory controller hierarchy

Definition

```
struct edac_mc_layer {
  enum edac_mc_layer_type type;
  unsigned size;
  bool is_virt_csrow;
};
```

Members

type layer type

size number of components per layer. For example, if the channel layer has two channels, size = 2

is_virt_csrow This layer is part of the "csrow" when old API compatibility mode is enabled. Otherwise, it is a channel

struct **rank_info**
contains the information for one DIMM rank

Definition

```
struct rank_info {
  int chan_idx;
  struct csrow_info *csrow;
  struct dimm_info *dimm;
  u32 ce_count;
};
```

Members

chan_idx channel number where the rank is (typically, 0 or 1)

csrow A pointer to the chip select row structure (the parent structure). The location of the rank is given by the (csrow->csrow_idx, chan_idx) vector.

dimm A pointer to the DIMM structure, where the DIMM label information is stored.

ce_count number of correctable errors for this rank

Description

FIXME: Currently, the EDAC core model will assume one DIMM per rank.
This is a bad assumption, but it makes this patch easier. Later patches in this series will fix this issue.

struct **edac_raw_error_desc**
Raw error report structure

Definition

```
struct edac_raw_error_desc {
  char location[LOCATION_SIZE];
  char label[(EDAC_MC_LABEL_LEN + 1 + sizeof(OTHER_LABEL)) * EDAC_MAX_
↪LABELS];
  long grain;
  u16 error_count;
  enum hw_event_mc_err_type type;
  int top_layer;
```

(continues on next page)

(continued from previous page)

```
  int mid_layer;
  int low_layer;
  unsigned long page_frame_number;
  unsigned long offset_in_page;
  unsigned long syndrome;
  const char *msg;
  const char *other_detail;
};
```

Members

location location of the error

label label of the affected DIMM(s)

grain minimum granularity for an error report, in bytes

error_count number of errors of the same type

type severity of the error (CE/UE/Fatal)

top_layer top layer of the error (layer[0])

mid_layer middle layer of the error (layer[1])

low_layer low layer of the error (layer[2])

page_frame_number page where the error happened

offset_in_page page offset

syndrome syndrome of the error (or 0 if unknown or if the syndrome is not applicable)

msg error message

other_detail other driver-specific detail about the error

struct dimm_info * **edac_get_dimm_by_index**(struct mem_ctl_info * mci, int index)

Get DIMM info at **index** from a memory controller

Parameters

struct mem_ctl_info * mci MC descriptor struct mem_ctl_info

int index index in the memory controller's DIMM array

Description

Returns a struct dimm_info * or NULL on failure.

struct dimm_info * **edac_get_dimm**(struct mem_ctl_info * mci, int layer0, int layer1, int layer2)

Get DIMM info from a memory controller given by [layer0,layer1,layer2] position

Parameters

struct mem_ctl_info * mci MC descriptor struct mem_ctl_info

int layer0 layer0 position

int layer1 layer1 position. Unused if n_layers < 2

int layer2 layer2 position. Unused if n_layers < 3

Description

For 1 layer, this function returns “dimms[layer0]”;

For 2 layers, this function is similar to allocating a two-dimensional array and returning “dimms[layer0][layer1]”;

For 3 layers, this function is similar to allocating a tri-dimensional array and returning “dimms[layer0][layer1][layer2]”;

struct mem_ctl_info * **edac_mc_alloc**(unsigned int mc_num, unsigned int n_layers, struct edac_mc_layer * layers, unsigned int sz_pvt)

Allocate and partially fill a struct `mem_ctl_info`.

Parameters

unsigned int mc_num Memory controller number

unsigned int n_layers Number of MC hierarchy layers

struct edac_mc_layer * layers Describes each layer as seen by the Memory Controller

unsigned int sz_pvt size of private storage needed

Description

Everything is kmalloc’ed as one big chunk - more efficient. Only can be used if all structures have the same lifetime - otherwise you have to allocate and initialize your own structures.

Use `edac_mc_free()` to free mc structures allocated by this function.

Note: drivers handle multi-rank memories in different ways: in some drivers, one multi-rank memory stick is mapped as one entry, while, in others, a single multi-rank memory stick would be mapped into several entries. Currently, this function will allocate multiple struct dimm_info on such scenarios, as grouping the multiple ranks require drivers change.

Return

On success, return a pointer to struct mem_ctl_info pointer; `NULL` otherwise

const char * **edac_get_owner**(void)

Return the owner’s mod_name of EDAC MC

Parameters

void no arguments

Return

Pointer to mod_name string when EDAC MC is owned. NULL otherwise.

void **edac_mc_free**(struct mem_ctl_info * mci)
Frees a previously allocated **mci** structure

Parameters

struct mem_ctl_info * mci pointer to a struct mem_ctl_info structure

bool **edac_has_mcs**(void)
Check if any MCs have been allocated.

Parameters

void no arguments

Return

True if MC instances have been registered successfully. False otherwise.

struct mem_ctl_info * **edac_mc_find**(int idx)
Search for a mem_ctl_info structure whose index is **idx**.

Parameters

int idx index to be seek

Description

If found, return a pointer to the structure. Else return NULL.

struct mem_ctl_info * **find_mci_by_dev**(struct device * dev)
Scan list of controllers looking for the one that manages the **dev** device.

Parameters

struct device * dev pointer to a struct device related with the MCI

Return

on success, returns a pointer to struct `mem_ctl_info`; `NULL` otherwise.

struct mem_ctl_info * **edac_mc_del_mc**(struct device * dev)
Remove sysfs entries for mci structure associated with **dev** and remove mci structure from global list.

Parameters

struct device * dev Pointer to struct `device` representing mci structure to remove.

Return

pointer to removed mci structure, or `NULL` if device not found.

int **edac_mc_find_csrow_by_page**(struct mem_ctl_info * mci, unsigned long page)
Ancillary routine to identify what csrow contains a memory page.

Parameters

struct mem_ctl_info * mci pointer to a struct mem_ctl_info structure

unsigned long page memory page to find

Return

on success, returns the csrow. -1 if not found.

void **edac_raw_mc_handle_error**(struct edac_raw_error_desc * e)
Reports a memory event to userspace without doing anything to discover the error location.

Parameters

struct edac_raw_error_desc * e error description

Description

This raw function is used internally by `edac_mc_handle_error()`. It should only be called directly when the hardware error come directly from BIOS, like in the case of APEI GHES driver.

void **edac_mc_handle_error**(const enum hw_event_mc_err_type type, struct mem_ctl_info * mci, const u16 error_count, const unsigned long page_frame_number, const unsigned long offset_in_page, const unsigned long syndrome, const int top_layer, const int mid_layer, const int low_layer, const char * msg, const char * other_detail)
Reports a memory event to userspace.

Parameters

const enum hw_event_mc_err_type type severity of the error (CE/UE/Fatal)

struct mem_ctl_info * mci a struct mem_ctl_info pointer

const u16 error_count Number of errors of the same type

const unsigned long page_frame_number mem page where the error occurred

const unsigned long offset_in_page offset of the error inside the page

const unsigned long syndrome ECC syndrome

const int top_layer Memory layer[0] position

const int mid_layer Memory layer[1] position

const int low_layer Memory layer[2] position

const char * msg Message meaningful to the end users that explains the event

const char * other_detail Technical details about the event that may help hardware manufacturers and EDAC developers to analyse the event

31.3 PCI Controllers

The EDAC subsystem provides a mechanism to handle PCI controllers by calling the `edac_pci_alloc_ctl_info()`. It will use the struct `edac_pci_ctl_info` to describe the PCI controllers.

struct edac_pci_ctl_info * **edac_pci_alloc_ctl_info**(unsigned int sz_pvt, const char * edac_pci_name)

Parameters

unsigned int sz_pvt size of the private info at struct `edac_pci_ctl_info`

const char * edac_pci_name name of the PCI device

Description

The alloc() function for the 'edac_pci' control info structure.

The chip driver will allocate one of these for each edac_pci it is going to control/register with the EDAC CORE.

Return

a pointer to struct `edac_pci_ctl_info` on success; `NULL` otherwise.

void **edac_pci_free_ctl_info**(struct edac_pci_ctl_info * pci)

Parameters

struct edac_pci_ctl_info * pci pointer to struct `edac_pci_ctl_info`

Description

Last action on the pci control structure.

Calls the remove sysfs information, which will unregister this control struct's kobj. When that kobj's ref count goes to zero, its release function will be call and then kfree() the memory.

int **edac_pci_alloc_index**(void)

Parameters

void no arguments

Return

allocated index number

int **edac_pci_add_device**(struct edac_pci_ctl_info * pci, int edac_idx)

Parameters

struct edac_pci_ctl_info * pci pointer to the edac_device structure to be added to the list

int edac_idx A unique numeric identifier to be assigned to the 'edac_pci' structure.

Description

edac_pci global list and create sysfs entries associated with edac_pci structure.

Return

0 on Success, or an error code on failure

struct edac_pci_ctl_info * **edac_pci_del_device**(struct device * dev)

Parameters

struct device * dev Pointer to 'struct device' representing edac_pci structure to remove

Description

Remove sysfs entries for specified edac_pci structure and then remove edac_pci structure from global list

Return

Pointer to removed edac_pci structure, or NULL if device not found

struct edac_pci_ctl_info * **edac_pci_create_generic_ctl**(struct device * dev, const char * mod_name)

Parameters

struct device * dev pointer to struct device;

const char * mod_name name of the PCI device

Description

A generic constructor for a PCI parity polling device Some systems have more than one domain of PCI busses. For systems with one domain, then this API will provide for a generic poller.

This routine calls the edac_pci_alloc_ctl_info() for the generic device, with default values

Return

Pointer to struct edac_pci_ctl_info on success, NULL on failure.

void **edac_pci_release_generic_ctl**(struct edac_pci_ctl_info * pci)

Parameters

struct edac_pci_ctl_info * pci pointer to struct edac_pci_ctl_info

Description

The release function of a generic EDAC PCI polling device

int **edac_pci_create_sysfs**(struct edac_pci_ctl_info * pci)

Parameters

struct edac_pci_ctl_info * pci pointer to struct edac_pci_ctl_info

Description

Create the controls/attributes for the specified EDAC PCI device

void **edac_pci_remove_sysfs**(struct edac_pci_ctl_info * pci)

Parameters

struct edac_pci_ctl_info * pci pointer to struct edac_pci_ctl_info

Description

remove the controls and attributes for this EDAC PCI device

31.4 EDAC Blocks

The EDAC subsystem also provides a generic mechanism to report errors on other parts of the hardware via `edac_device_alloc_ctl_info()` function.

The structures `edac_dev_sysfs_block_attribute`, `edac_device_block`, `edac_device_instance` and `edac_device_ctl_info` provide a generic or abstract 'edac_device' representation at sysfs.

This set of structures and the code that implements the APIs for the same, provide for registering EDAC type devices which are NOT standard memory or PCI, like:

- CPU caches (L1 and L2)
- DMA engines
- Core CPU switches
- Fabric switch units
- PCIe interface controllers
- other EDAC/ECC type devices that can be monitored for errors, etc.

It allows for a 2 level set of hierarchy.

For example, a cache could be composed of L1, L2 and L3 levels of cache. Each CPU core would have its own L1 cache, while sharing L2 and maybe L3 caches. On such case, those can be represented via the following sysfs nodes:

```
/sys/devices/system/edac/..

pci/            <existing pci directory (if available)>
mc/             <existing memory device directory>
cpu/cpu0/..     <L1 and L2 block directory>
        /L1-cache/ce_count
                 /ue_count
        /L2-cache/ce_count
                 /ue_count
cpu/cpu1/..     <L1 and L2 block directory>
        /L1-cache/ce_count
                 /ue_count
        /L2-cache/ce_count
                 /ue_count
...

the L1 and L2 directories would be "edac_device_block's"
```

int **edac_device_add_device**(struct edac_device_ctl_info * edac_dev)

Parameters

struct edac_device_ctl_info * edac_dev pointer to edac_device structure to be added to the list 'edac_device' structure.

Description

edac_device global list and create sysfs entries associated with edac_device structure.

Return

0 on Success, or an error code on failure

struct edac_device_ctl_info * **edac_device_del_device**(struct device * dev)

Parameters

struct device * dev Pointer to struct `device` representing the edac device structure to remove.

Description

Remove sysfs entries for specified edac_device structure and then remove edac_device structure from global list

Return

Pointer to removed edac_device structure, or `NULL` if device not found.

void **edac_device_handle_ce_count**(struct edac_device_ctl_info * edac_dev, unsigned int count, int inst_nr, int block_nr, const char * msg)

Parameters

struct edac_device_ctl_info * edac_dev pointer to struct `edac_device_ctl_info`

unsigned int count Number of errors to log.

int inst_nr number of the instance where the CE error happened

int block_nr number of the block where the CE error happened

const char * msg message to be printed

void **edac_device_handle_ue_count**(struct edac_device_ctl_info * edac_dev, unsigned int count, int inst_nr, int block_nr, const char * msg)

Parameters

struct edac_device_ctl_info * edac_dev pointer to struct `edac_device_ctl_info`

unsigned int count Number of errors to log.

int inst_nr number of the instance where the CE error happened

int block_nr number of the block where the CE error happened

const char * msg message to be printed

void **edac_device_handle_ce**(struct edac_device_ctl_info * edac_dev, int inst_nr, int block_nr, const char * msg)

Parameters

struct edac_device_ctl_info * edac_dev pointer to struct edac_device_ctl_info

int inst_nr number of the instance where the CE error happened

int block_nr number of the block where the CE error happened

const char * msg message to be printed

void **edac_device_handle_ue**(struct edac_device_ctl_info * edac_dev, int inst_nr, int block_nr, const char * msg)

Parameters

struct edac_device_ctl_info * edac_dev pointer to struct edac_device_ctl_info

int inst_nr number of the instance where the UE error happened

int block_nr number of the block where the UE error happened

const char * msg message to be printed

int **edac_device_alloc_index**(void)

Parameters

void no arguments

Return

allocated index number

CHAPTER

THIRTYTWO

SCSI INTERFACES GUIDE

Author James Bottomley

Author Rob Landley

32.1 Introduction

32.1.1 Protocol vs bus

Once upon a time, the Small Computer Systems Interface defined both a parallel I/O bus and a data protocol to connect a wide variety of peripherals (disk drives, tape drives, modems, printers, scanners, optical drives, test equipment, and medical devices) to a host computer.

Although the old parallel (fast/wide/ultra) SCSI bus has largely fallen out of use, the SCSI command set is more widely used than ever to communicate with devices over a number of different busses.

The SCSI protocol is a big-endian peer-to-peer packet based protocol. SCSI commands are 6, 10, 12, or 16 bytes long, often followed by an associated data payload.

SCSI commands can be transported over just about any kind of bus, and are the default protocol for storage devices attached to USB, SATA, SAS, Fibre Channel, FireWire, and ATAPI devices. SCSI packets are also commonly exchanged over Infiniband, I2O, TCP/IP (iSCSI), even Parallel ports.

32.1.2 Design of the Linux SCSI subsystem

The SCSI subsystem uses a three layer design, with upper, mid, and low layers. Every operation involving the SCSI subsystem (such as reading a sector from a disk) uses one driver at each of the 3 levels: one upper layer driver, one lower layer driver, and the SCSI midlayer.

The SCSI upper layer provides the interface between userspace and the kernel, in the form of block and char device nodes for I/O and ioctl(). The SCSI lower layer contains drivers for specific hardware devices.

In between is the SCSI mid-layer, analogous to a network routing layer such as the IPv4 stack. The SCSI mid-layer routes a packet based data protocol between the upper layer’ s /dev nodes and the corresponding devices in the lower layer.

It manages command queues, provides error handling and power management functions, and responds to ioctl() requests.

32.2 SCSI upper layer

The upper layer supports the user-kernel interface by providing device nodes.

32.2.1 sd (SCSI Disk)

sd (sd_mod.o)

32.2.2 sr (SCSI CD-ROM)

sr (sr_mod.o)

32.2.3 st (SCSI Tape)

st (st.o)

32.2.4 sg (SCSI Generic)

sg (sg.o)

32.2.5 ch (SCSI Media Changer)

ch (ch.c)

32.3 SCSI mid layer

32.3.1 SCSI midlayer implementation

include/scsi/scsi_device.h

struct **scsi_vpd**
SCSI Vital Product Data

Definition

```
struct scsi_vpd {
  struct rcu_head rcu;
  int len;
  unsigned char   data[];
};
```

Members

rcu For kfree_rcu().

len Length in bytes of **data**.

data VPD data as defined in various T10 SCSI standard documents.

shost_for_each_device(sdev, shost)
iterate over all devices of a host

Parameters

sdev the `struct scsi_device` to use as a cursor

shost the `struct scsi_host` to iterate over

Description

Iterator that returns each device attached to **shost**. This loop takes a reference on each device and releases it at the end. If you break out of the loop, you must call scsi_device_put(sdev).

__shost_for_each_device(sdev, shost)
iterate over all devices of a host (UNLOCKED)

Parameters

sdev the `struct scsi_device` to use as a cursor

shost the `struct scsi_host` to iterate over

Description

Iterator that returns each device attached to **shost**. It does _not_ take a reference on the scsi_device, so the whole loop must be protected by shost->host_lock.

Note

The only reason to use this is because you need to access the device list in interrupt context. Otherwise you really want to use shost_for_each_device instead.

int **scsi_device_supports_vpd**(struct scsi_device * sdev)
test if a device supports VPD pages

Parameters

struct scsi_device * sdev the `struct scsi_device` to test

Description

If the 'try_vpd_pages' flag is set it takes precedence. Otherwise we will assume VPD pages are supported if the SCSI level is at least SPC-3 and 'skip_vpd_pages' is not set.

drivers/scsi/scsi.c

Main file for the SCSI midlayer.

int **scsi_change_queue_depth**(struct scsi_device * sdev, int depth)
change a device's queue depth

Parameters

struct scsi_device * sdev SCSI Device in question

int depth number of commands allowed to be queued to the driver

Description

Sets the device queue depth and returns the new value.

int **scsi_track_queue_full**(struct scsi_device * sdev, int depth)
track QUEUE_FULL events to adjust queue depth

Parameters

struct scsi_device * sdev SCSI Device in question

int depth Current number of outstanding SCSI commands on this device, not counting the one returned as QUEUE_FULL.

Description

This function will track successive QUEUE_FULL events on a specific SCSI device to determine if and when there is a need to adjust the queue depth on the device.

Lock Status: None held on entry

Return

0 - No change needed, >0 - Adjust queue depth to this new depth,

-1 - Drop back to untagged operation using host->cmd_per_lun as the untagged command depth

Notes

Low level drivers may call this at any time and we will do "The Right Thing." We are interrupt context safe.

int **scsi_get_vpd_page**(struct scsi_device * sdev, u8 page, unsigned char * buf, int buf_len)
Get Vital Product Data from a SCSI device

Parameters

struct scsi_device * sdev The device to ask

u8 page Which Vital Product Data to return

unsigned char * buf where to store the VPD

int buf_len number of bytes in the VPD buffer area

Description

SCSI devices may optionally supply Vital Product Data. Each 'page' of VPD is defined in the appropriate SCSI document (eg SPC, SBC). If the device supports this VPD page, this routine returns a pointer to a buffer containing the data from that page. The caller is responsible for calling kfree() on this pointer when it is no longer needed. If we cannot retrieve the VPD page this routine returns `NULL`.

int **scsi_report_opcode**(struct scsi_device * sdev, unsigned char * buffer, unsigned int len, unsigned char opcode)
Find out if a given command opcode is supported

Parameters

struct scsi_device * sdev scsi device to query

unsigned char * buffer scratch buffer (must be at least 20 bytes long)

unsigned int len length of buffer

unsigned char opcode opcode for command to look up

Description

Uses the REPORT SUPPORTED OPERATION CODES to look up the given opcode. Returns -EINVAL if RSOC fails, 0 if the command opcode is unsupported and 1 if the device claims to support the command.

int **scsi_device_get**(struct scsi_device * sdev)
get an additional reference to a scsi_device

Parameters

struct scsi_device * sdev device to get a reference to

Description

Gets a reference to the scsi_device and increments the use count of the underlying LLDD module. You must hold host_lock of the parent Scsi_Host or already have a reference when calling this.

This will fail if a device is deleted or cancelled, or when the LLD module is in the process of being unloaded.

void **scsi_device_put**(struct scsi_device * sdev)
release a reference to a scsi_device

Parameters

struct scsi_device * sdev device to release a reference on.

Description

Release a reference to the scsi_device and decrements the use count of the underlying LLDD module. The device is freed once the last user vanishes.

void **starget_for_each_device**(struct scsi_target * starget, void * data,
void (*fn)(struct scsi_device *, void *))
helper to walk all devices of a target

Parameters

struct scsi_target * starget target whose devices we want to iterate over.

void * data Opaque passed to each function call.

void (*)(struct scsi_device *, void *) fn Function to call on each device

Description

This traverses over each device of **starget**. The devices have a reference that must be released by scsi_host_put when breaking out of the loop.

void **__starget_for_each_device**(struct scsi_target * starget, void * data,
void (*fn)(struct scsi_device *, void *))
helper to walk all devices of a target (UNLOCKED)

Parameters

struct scsi_target * starget target whose devices we want to iterate over.

void * data parameter for callback **fn()**

void (*)(struct scsi_device *, void *) fn callback function that is invoked for each device

Description

This traverses over each device of **starget**. It does _not_ take a reference on the scsi_device, so the whole loop must be protected by shost->host_lock.

Note

The only reason why drivers would want to use this is because they need to access the device list in irq context. Otherwise you really want to use starget_for_each_device instead.

struct scsi_device * **__scsi_device_lookup_by_target**(struct scsi_target * starget, u64 lun)

find a device given the target (UNLOCKED)

Parameters

struct scsi_target * starget SCSI target pointer

u64 lun SCSI Logical Unit Number

Description

Looks up the scsi_device with the specified **lun** for a given **starget**. The returned scsi_device does not have an additional reference. You must hold the host's host_lock over this call and any access to the returned scsi_device. A scsi_device in state SDEV_DEL is skipped.

Note

The only reason why drivers should use this is because they need to access the device list in irq context. Otherwise you really want to use scsi_device_lookup_by_target instead.

struct scsi_device * **scsi_device_lookup_by_target**(struct scsi_target * starget, u64 lun)

find a device given the target

Parameters

struct scsi_target * starget SCSI target pointer

u64 lun SCSI Logical Unit Number

Description

Looks up the scsi_device with the specified **lun** for a given **starget**. The returned scsi_device has an additional reference that needs to be released with scsi_device_put once you're done with it.

struct scsi_device * **__scsi_device_lookup**(struct Scsi_Host * shost, uint channel, uint id, u64 lun)

find a device given the host (UNLOCKED)

Parameters

struct Scsi_Host * shost SCSI host pointer

uint channel SCSI channel (zero if only one channel)

uint id SCSI target number (physical unit number)

u64 lun SCSI Logical Unit Number

Description

Looks up the scsi_device with the specified **channel**, **id**, **lun** for a given host. The returned scsi_device does not have an additional reference. You must hold the host's host_lock over this call and any access to the returned scsi_device.

Note

The only reason why drivers would want to use this is because they need to access the device list in irq context. Otherwise you really want to use scsi_device_lookup instead.

struct scsi_device * **scsi_device_lookup**(struct Scsi_Host * shost, uint channel, uint id, u64 lun)
find a device given the host

Parameters

struct Scsi_Host * shost SCSI host pointer

uint channel SCSI channel (zero if only one channel)

uint id SCSI target number (physical unit number)

u64 lun SCSI Logical Unit Number

Description

Looks up the scsi_device with the specified **channel**, **id**, **lun** for a given host. The returned scsi_device has an additional reference that needs to be released with scsi_device_put once you're done with it.

drivers/scsi/scsicam.c

SCSI Common Access Method support functions, for use with HDIO_GETGEO, etc.

unsigned char * **scsi_bios_ptable**(struct block_device * dev)
Read PC partition table out of first sector of device.

Parameters

struct block_device * dev from this device

Description

Reads the first sector from the device and returns 0x42 bytes starting at offset `0x1be`.

Return

partition table in kmalloc(GFP_KERNEL) memory, or NULL on error.

bool **scsi_partsize**(struct block_device * bdev, sector_t capacity, int geom)
Parse cylinders/heads/sectors from PC partition table

Parameters

struct block_device * bdev block device to parse

sector_t capacity size of the disk in sectors

int geom output in form of [hds, cylinders, sectors]

Description

Determine the BIOS mapping/geometry used to create the partition table, storing the results in **geom**.

Return

`false` on failure, `true` on success.

int **scsicam_bios_param**(struct block_device * bdev, sector_t capacity, int * ip)
Determine geometry of a disk in cylinders/heads/sectors.

Parameters

struct block_device * bdev which device

sector_t capacity size of the disk in sectors

int * ip return value: ip[0]=heads, ip[1]=sectors, ip[2]=cylinders

Description

determine the BIOS mapping/geometry used for a drive in a SCSI-CAM system, storing the results in ip as required by the HDIO_GETGEO ioctl().

Return

-1 on failure, 0 on success.

drivers/scsi/scsi_error.c

Common SCSI error/timeout handling routines.

void **scsi_schedule_eh**(struct Scsi_Host * shost)
schedule EH for SCSI host

Parameters

struct Scsi_Host * shost SCSI host to invoke error handling on.

Description

Schedule SCSI EH without scmd.

int **scsi_block_when_processing_errors**(struct scsi_device * sdev)
Prevent cmds from being queued.

Parameters

struct scsi_device * sdev Device on which we are performing recovery.

Description

We block until the host is out of error recovery, and then check to see whether the host or the device is offline.

Return value: 0 when dev was taken offline by error recovery. 1 OK to proceed.

int **scsi_check_sense**(struct scsi_cmnd * scmd)
Examine scsi cmd sense

Parameters

struct scsi_cmnd * scmd Cmd to have sense checked.

Description

Return value: SUCCESS or FAILED or NEEDS_RETRY or ADD_TO_MLQUEUE

Notes

When a deferred error is detected the current command has not been executed and needs retrying.

void **scsi_eh_prep_cmnd**(struct scsi_cmnd * scmd, struct scsi_eh_save * ses, unsigned char * cmnd, int cmnd_size, unsigned sense_bytes)
Save a scsi command info as part of error recovery

Parameters

struct scsi_cmnd * scmd SCSI command structure to hijack

struct scsi_eh_save * ses structure to save restore information

unsigned char * cmnd CDB to send. Can be NULL if no new cmnd is needed

int cmnd_size size in bytes of **cmnd** (must be <= BLK_MAX_CDB)

unsigned sense_bytes size of sense data to copy. or 0 (if != 0 **cmnd** is ignored)

Description

This function is used to save a scsi command information before re-execution as part of the error recovery process. If **sense_bytes** is 0 the command sent must be one that does not transfer any data. If **sense_bytes** != 0 **cmnd** is ignored and this functions sets up a REQUEST_SENSE command and cmnd buffers to read **sense_bytes** into **scmd->sense_buffer**.

void **scsi_eh_restore_cmnd**(struct scsi_cmnd * scmd, struct scsi_eh_save * ses)
Restore a scsi command info as part of error recovery

Parameters

struct scsi_cmnd * scmd SCSI command structure to restore

struct scsi_eh_save * ses saved information from a coresponding call to scsi_eh_prep_cmnd

Description

Undo any damage done by above `scsi_eh_prep_cmnd()`.

void **scsi_eh_finish_cmd**(struct scsi_cmnd * scmd, struct list_head * done_q)
Handle a cmd that eh is finished with.

Parameters

struct scsi_cmnd * scmd Original SCSI cmd that eh has finished.

struct list_head * done_q Queue for processed commands.

Notes

We don't want to use the normal command completion while we are are still handling errors - it may cause other commands to be queued, and that would disturb what we are doing. Thus we really want to keep a list of pending commands for final completion, and once we are ready to leave error handling we handle completion for real.

int **scsi_eh_get_sense**(struct list_head * work_q, struct list_head * done_q)
Get device sense data.

Parameters

struct list_head * work_q Queue of commands to process.

struct list_head * done_q Queue of processed commands.

Description

See if we need to request sense information. if so, then get it now, so we have a better idea of what to do.

Notes

This has the unfortunate side effect that if a shost adapter does not automatically request sense information, we end up shutting it down before we request it.

All drivers should request sense information internally these days, so for now all I have to say is tough noogies if you end up in here.

XXX: Long term this code should go away, but that needs an audit of all LLDDs first.

void **scsi_eh_ready_devs**(struct Scsi_Host * shost, struct list_head * work_q, struct list_head * done_q)
check device ready state and recover if not.

Parameters

struct Scsi_Host * shost host to be recovered.

struct list_head * work_q `list_head` for pending commands.

struct list_head * done_q `list_head` for processed commands.

void **scsi_eh_flush_done_q**(struct list_head * done_q)
finish processed commands or retry them.

Parameters

struct list_head * done_q list_head of processed commands.

bool **scsi_get_sense_info_fld**(const u8 * sense_buffer, int sb_len, u64 * info_out)
get information field from sense data (either fixed or descriptor format)

Parameters

const u8 * sense_buffer byte array of sense data

int sb_len number of valid bytes in sense_buffer

u64 * info_out pointer to 64 integer where 8 or 4 byte information field will be placed if found.

Description

Return value: true if information field found, false if not found.

drivers/scsi/scsi_devinfo.c

Manage scsi_dev_info_list, which tracks blacklisted and whitelisted devices.

int **scsi_dev_info_list_add**(int compatible, char * vendor, char * model, char * strflags, blist_flags_t flags)

add one dev_info list entry.

Parameters

int compatible if true, null terminate short strings. Otherwise space pad.

char * vendor vendor string

char * model model (product) string

char * strflags integer string

blist_flags_t flags if strflags NULL, use this flag value

Description

Create and add one dev_info entry for **vendor**, **model**, **strflags** or **flag**. If **compatible**, add to the tail of the list, do not space pad, and set devinfo->compatible. The scsi_static_device_list entries are added with **compatible** 1 and **clfags** NULL.

Return

0 OK, -error on failure.

struct scsi_dev_info_list * **scsi_dev_info_list_find**(const char * vendor, const char * model, enum scsi_devinfo_key key)

find a matching dev_info list entry.

Parameters

const char * vendor full vendor string

const char * model full model (product) string

enum scsi_devinfo_key key specify list to use

Description

Finds the first dev_info entry matching **vendor**, **model** in list specified by **key**.

Return

pointer to matching entry, or ERR_PTR on failure.

int **scsi_dev_info_list_add_str**(char * dev_list)
parse dev_list and add to the scsi_dev_info_list.

Parameters

char * dev_list string of device flags to add

Description

Parse dev_list, and add entries to the scsi_dev_info_list. dev_list is of the form "vendor:product:flag,vendor:product:flag". dev_list is modified via strsep. Can be called for command line addition, for proc or mabye a sysfs interface.

Return

0 if OK, -error on failure.

blist_flags_t **scsi_get_device_flags**(struct scsi_device * sdev, const unsigned char * vendor, const unsigned char * model)
get device specific flags from the dynamic device list.

Parameters

struct scsi_device * sdev scsi_device to get flags for

const unsigned char * vendor vendor name

const unsigned char * model model name

Description

Search the global scsi_dev_info_list (specified by list zero) for an entry matching **vendor** and **model**, if found, return the matching flags value, else return the host or global default settings. Called during scan time.

void **scsi_exit_devinfo**(void)
remove /proc/scsi/device_info & the scsi_dev_info_list

Parameters

void no arguments

int **scsi_init_devinfo**(void)
set up the dynamic device list.

Parameters

void no arguments

Description

Add command line entries from scsi_dev_flags, then add scsi_static_device_list entries to the scsi device info list.

drivers/scsi/scsi_ioctl.c

Handle ioctl() calls for SCSI devices.

int **scsi_ioctl**(struct scsi_device * sdev, int cmd, void __user * arg)
Dispatch ioctl to scsi device

Parameters

struct scsi_device * sdev scsi device receiving ioctl

int cmd which ioctl is it

void __user * arg data associated with ioctl

Description

The `scsi_ioctl()` function differs from most ioctls in that it does not take a major/minor number as the dev field. Rather, it takes a pointer to a `struct scsi_device`.

drivers/scsi/scsi_lib.c

SCSI queuing library.

int **__scsi_execute**(struct scsi_device * sdev, const unsigned char * cmd, int data_direction, void * buffer, unsigned bufflen, unsigned char * sense, struct scsi_sense_hdr * sshdr, int timeout, int retries, u64 flags, req_flags_t rq_flags, int * resid)
insert request and wait for the result

Parameters

struct scsi_device * sdev scsi device

const unsigned char * cmd scsi command

int data_direction data direction

void * buffer data buffer

unsigned bufflen len of buffer

unsigned char * sense optional sense buffer

struct scsi_sense_hdr * sshdr optional decoded sense header

int timeout request timeout in seconds

int retries number of times to retry request

u64 flags flags for ->cmd_flags

req_flags_t rq_flags flags for ->rq_flags

int * resid optional residual length

Description

Returns the scsi_cmnd result field if a command was executed, or a negative Linux error code if we didn’t get that far.

blk_status_t **scsi_init_io**(struct scsi_cmnd * cmd)
SCSI I/O initialization function.

Parameters

struct scsi_cmnd * cmd command descriptor we wish to initialize

Return

- BLK_STS_OK - on success
- BLK_STS_RESOURCE - if the failure is retryable
- BLK_STS_IOERR - if the failure is fatal

struct scsi_device * **scsi_device_from_queue**(struct request_queue * q)
return sdev associated with a request_queue

Parameters

struct request_queue * q The request queue to return the sdev from

Description

Return the sdev associated with a request queue or NULL if the request_queue does not reference a SCSI device.

void **scsi_block_requests**(struct Scsi_Host * shost)
Utility function used by low-level drivers to prevent further commands from being queued to the device.

Parameters

struct Scsi_Host * shost host in question

Description

There is no timer nor any other means by which the requests get unblocked other than the low-level driver calling `scsi_unblock_requests()`.

void **scsi_unblock_requests**(struct Scsi_Host * shost)
Utility function used by low-level drivers to allow further commands to be queued to the device.

Parameters

struct Scsi_Host * shost host in question

Description

There is no timer nor any other means by which the requests get unblocked other than the low-level driver calling `scsi_unblock_requests()`. This is done as an API function so that changes to the internals of the scsi mid-layer won't require wholesale changes to drivers that use this feature.

int **scsi_mode_select**(struct scsi_device * sdev, int pf, int sp, int modepage, unsigned char * buffer, int len, int timeout, int retries, struct scsi_mode_data * data, struct scsi_sense_hdr * sshdr)
issue a mode select

Parameters

struct scsi_device * sdev SCSI device to be queried

int pf Page format bit (1 == standard, 0 == vendor specific)

int sp Save page bit (0 == don't save, 1 == save)

int modepage mode page being requested

unsigned char * buffer request buffer (may not be smaller than eight bytes)

int len length of request buffer.

int timeout command timeout

int retries number of retries before failing

struct scsi_mode_data * data returns a structure abstracting the mode header data

struct scsi_sense_hdr * sshdr place to put sense data (or NULL if no sense to be collected). must be SCSI_SENSE_BUFFERSIZE big.

Returns zero if successful; negative error number or scsi status on error

int **scsi_mode_sense**(struct scsi_device * sdev, int dbd, int modepage, unsigned char * buffer, int len, int timeout, int retries, struct scsi_mode_data * data, struct scsi_sense_hdr * sshdr)

issue a mode sense, falling back from 10 to six bytes if necessary.

Parameters

struct scsi_device * sdev SCSI device to be queried

int dbd set if mode sense will allow block descriptors to be returned

int modepage mode page being requested

unsigned char * buffer request buffer (may not be smaller than eight bytes)

int len length of request buffer.

int timeout command timeout

int retries number of retries before failing

struct scsi_mode_data * data returns a structure abstracting the mode header data

struct scsi_sense_hdr * sshdr place to put sense data (or NULL if no sense to be collected). must be SCSI_SENSE_BUFFERSIZE big.

Returns zero if unsuccessful, or the header offset (either 4 or 8 depending on whether a six or ten byte command was issued) if successful.

int **scsi_test_unit_ready**(struct scsi_device * sdev, int timeout, int retries, struct scsi_sense_hdr * sshdr)

test if unit is ready

Parameters

struct scsi_device * sdev scsi device to change the state of.

int timeout command timeout

int retries number of retries before failing

struct scsi_sense_hdr * sshdr outpout pointer for decoded sense information.

Returns zero if unsuccessful or an error if TUR failed. For removable media, UNIT_ATTENTION sets ->changed flag.

int **scsi_device_set_state**(struct scsi_device * sdev, enum scsi_device_state state)
Take the given device through the device state model.

Parameters

struct scsi_device * sdev scsi device to change the state of.

enum scsi_device_state state state to change to.

Returns zero if successful or an error if the requested transition is illegal.

void **sdev_evt_send**(struct scsi_device * sdev, struct scsi_event * evt)
send asserted event to uevent thread

Parameters

struct scsi_device * sdev scsi_device event occurred on

struct scsi_event * evt event to send

Assert scsi device event asynchronously.

struct scsi_event * **sdev_evt_alloc**(enum scsi_device_event evt_type, gfp_t gfpflags)
allocate a new scsi event

Parameters

enum scsi_device_event evt_type type of event to allocate

gfp_t gfpflags GFP flags for allocation

Allocates and returns a new scsi_event.

void **sdev_evt_send_simple**(struct scsi_device * sdev, enum scsi_device_event evt_type, gfp_t gfpflags)
send asserted event to uevent thread

Parameters

struct scsi_device * sdev scsi_device event occurred on

enum scsi_device_event evt_type type of event to send

gfp_t gfpflags GFP flags for allocation

Assert scsi device event asynchronously, given an event type.

int **scsi_device_quiesce**(struct scsi_device * sdev)
Block user issued commands.

Parameters

struct scsi_device * sdev scsi device to quiesce.

This works by trying to transition to the SDEV_QUIESCE state (which must be a legal transition). When the device is in this state, only special requests will be accepted, all others will be deferred. Since special requests may also be requeued requests, a successful return doesn't guarantee the device will be totally quiescent.

Must be called with user context, may sleep.

Returns zero if unsuccessful or an error if not.

void **scsi_device_resume**(struct scsi_device * sdev)
Restart user issued commands to a quiesced device.

Parameters

struct scsi_device * sdev scsi device to resume.

Moves the device from quiesced back to running and restarts the queues.

Must be called with user context, may sleep.

int **scsi_internal_device_block_nowait**(struct scsi_device * sdev)
try to transition to the SDEV_BLOCK state

Parameters

struct scsi_device * sdev device to block

Description

Pause SCSI command processing on the specified device. Does not sleep.

Returns zero if successful or a negative error code upon failure.

Notes

This routine transitions the device to the SDEV_BLOCK state (which must be a legal transition). When the device is in this state, command processing is paused until the device leaves the SDEV_BLOCK state. See also `scsi_internal_device_unblock_nowait()`.

int **scsi_internal_device_unblock_nowait**(struct scsi_device * sdev, enum scsi_device_state new_state)
resume a device after a block request

Parameters

struct scsi_device * sdev device to resume

enum scsi_device_state new_state state to set the device to after unblocking

Description

Restart the device queue for a previously suspended SCSI device. Does not sleep.

Returns zero if successful or a negative error code upon failure.

Notes

This routine transitions the device to the SDEV_RUNNING state or to one of the offline states (which must be a legal transition) allowing the midlayer to goose the queue for this device.

void * **scsi_kmap_atomic_sg**(struct scatterlist * sgl, int sg_count, size_t * offset, size_t * len)
find and atomically map an sg-elemnt

Parameters

struct scatterlist * sgl scatter-gather list

int sg_count number of segments in sg

size_t * offset offset in bytes into sg, on return offset into the mapped area

size_t * len bytes to map, on return number of bytes mapped

Description

Returns virtual address of the start of the mapped page

void **scsi_kunmap_atomic_sg**(void * virt)
atomically unmap a virtual address, previously mapped with scsi_kmap_atomic_sg

Parameters

void * virt virtual address to be unmapped

int **scsi_vpd_lun_id**(struct scsi_device * sdev, char * id, size_t id_len)
return a unique device identification

Parameters

struct scsi_device * sdev SCSI device

char * id buffer for the identification

size_t id_len length of the buffer

Description

Copies a unique device identification into **id** based on the information in the VPD page 0x83 of the device. The string will be formatted as a SCSI name string.

Returns the length of the identification or error on failure. If the identifier is longer than the supplied buffer the actual identifier length is returned and the buffer is not zero-padded.

drivers/scsi/scsi_lib_dma.c

SCSI library functions depending on DMA (map and unmap scatter-gather lists).

int **scsi_dma_map**(struct scsi_cmnd * cmd)
perform DMA mapping against command's sg lists

Parameters

struct scsi_cmnd * cmd scsi command

Description

Returns the number of sg lists actually used, zero if the sg lists is NULL, or -ENOMEM if the mapping failed.

void **scsi_dma_unmap**(struct scsi_cmnd * cmd)
unmap command' s sg lists mapped by scsi_dma_map

Parameters

struct scsi_cmnd * cmd scsi command

drivers/scsi/scsi_proc.c

The functions in this file provide an interface between the PROC file system and the SCSI device drivers It is mainly used for debugging, statistics and to pass information directly to the lowlevel driver. I.E. plumbing to manage /proc/scsi/*

void **scsi_proc_hostdir_add**(struct scsi_host_template * sht)
Create directory in /proc for a scsi host

Parameters

struct scsi_host_template * sht owner of this directory

Description

Sets sht->proc_dir to the new directory.

void **scsi_proc_hostdir_rm**(struct scsi_host_template * sht)
remove directory in /proc for a scsi host

Parameters

struct scsi_host_template * sht owner of directory

void **scsi_proc_host_add**(struct Scsi_Host * shost)
Add entry for this host to appropriate /proc dir

Parameters

struct Scsi_Host * shost host to add

void **scsi_proc_host_rm**(struct Scsi_Host * shost)
remove this host' s entry from /proc

Parameters

struct Scsi_Host * shost which host

int **proc_print_scsidevice**(struct device * dev, void * data)
return data about this host

Parameters

struct device * dev A scsi device

void * data `struct seq_file` to output to.

Description

prints Host, Channel, Id, Lun, Vendor, Model, Rev, Type, and revision.

int **scsi_add_single_device**(uint host, uint channel, uint id, uint lun)
Respond to user request to probe for/add device

Parameters

uint host user-supplied decimal integer

uint channel user-supplied decimal integer

uint id user-supplied decimal integer

uint lun user-supplied decimal integer

Description

called by writing "scsi add-single-device" to /proc/scsi/scsi.

does `scsi_host_lookup()` and either user_scan() if that transport type supports it, or else scsi_scan_host_selected()

Note

this seems to be aimed exclusively at SCSI parallel busses.

int **scsi_remove_single_device**(uint host, uint channel, uint id, uint lun)
Respond to user request to remove a device

Parameters

uint host user-supplied decimal integer

uint channel user-supplied decimal integer

uint id user-supplied decimal integer

uint lun user-supplied decimal integer

Description

called by writing "scsi remove-single-device" to /proc/scsi/scsi. Does a `scsi_device_lookup()` and `scsi_remove_device()`

ssize_t **proc_scsi_write**(struct file * file, const char __user * buf,
size_t length, loff_t * ppos)
handle writes to /proc/scsi/scsi

Parameters

struct file * file not used

const char __user * buf buffer to write

size_t length length of buf, at most PAGE_SIZE

loff_t * ppos not used

Description

this provides a legacy mechanism to add or remove devices by Host, Channel, ID, and Lun. To use, "echo 'scsi add-single-device 0 1 2 3' > /proc/scsi/scsi" or "echo 'scsi remove-single-device 0 1 2 3' > /proc/scsi/scsi" with "0 1 2 3" replaced by the Host, Channel, Id, and Lun.

Note

this seems to be aimed at parallel SCSI. Most modern busses (USB, SATA, Firewire, Fibre Channel, etc) dynamically assign these values to provide a unique identifier and nothing more.

int **proc_scsi_open**(struct inode * inode, struct file * file)
glue function

Parameters

struct inode * inode not used

struct file * file passed to single_open()

Description

Associates proc_scsi_show with this file

int **scsi_init_procfs**(void)
create scsi and scsi/scsi in procfs

Parameters

void no arguments

void **scsi_exit_procfs**(void)
Remove scsi/scsi and scsi from procfs

Parameters

void no arguments

drivers/scsi/scsi_netlink.c

Infrastructure to provide async events from transports to userspace via netlink, using a single NETLINK_SCSITRANSPORT protocol for all transports. See the original patch submission for more details.

void **scsi_nl_rcv_msg**(struct sk_buff * skb)
Receive message handler.

Parameters

struct sk_buff * skb socket receive buffer

Description

Extracts message from a receive buffer. Validates message header and calls appropriate transport message handler

void **scsi_netlink_init**(void)
Called by SCSI subsystem to initialize the SCSI transport netlink interface

Parameters

void no arguments

void **scsi_netlink_exit**(void)
Called by SCSI subsystem to disable the SCSI transport netlink interface

Parameters

void no arguments

drivers/scsi/scsi_scan.c

Scan a host to determine which (if any) devices are attached. The general scanning/probing algorithm is as follows, exceptions are made to it depending on device specific flags, compilation options, and global variable (boot or module load time) settings. A specific LUN is scanned via an INQUIRY command; if the LUN has a device attached, a scsi_device is allocated and setup for it. For every id of every channel on the given host, start by scanning LUN 0. Skip hosts that don't respond at all to a scan of LUN 0. Otherwise, if LUN 0 has a device attached, allocate and setup a scsi_device for it. If target is SCSI-3 or up, issue a REPORT LUN, and scan all of the LUNs returned by the REPORT LUN; else, sequentially scan LUNs up until some maximum is reached, or a LUN is seen that cannot have a device attached to it.

int **scsi_complete_async_scans**(void)
Wait for asynchronous scans to complete

Parameters

void no arguments

Description

When this function returns, any host which started scanning before this function was called will have finished its scan. Hosts which started scanning after this function was called may or may not have finished.

void **scsi_unlock_floptical**(struct scsi_device * sdev, unsigned char * result)
unlock device via a special MODE SENSE command

Parameters

struct scsi_device * sdev scsi device to send command to

unsigned char * result area to store the result of the MODE SENSE

Description

Send a vendor specific MODE SENSE (not a MODE SELECT) command. Called for BLIST_KEY devices.

struct scsi_device * **scsi_alloc_sdev**(struct scsi_target * starget, u64 lun, void * hostdata)
allocate and setup a scsi_Device

Parameters

struct scsi_target * starget which target to allocate a `scsi_device` for

u64 lun which lun

void * hostdata usually NULL and set by ->slave_alloc instead

Description

Allocate, initialize for io, and return a pointer to a scsi_Device. Stores the **shost**, **channel**, **id**, and **lun** in the scsi_Device, and adds scsi_Device to the appropriate list.

Return value: scsi_Device pointer, or NULL on failure.

void **scsi_target_reap_ref_release**(struct kref * kref)
remove target from visibility

Parameters

struct kref * kref the reap_ref in the target being released

Description

Called on last put of reap_ref, which is the indication that no device under this target is visible anymore, so render the target invisible in sysfs. Note: we have to be in user context here because the target reaps should be done in places where the scsi device visibility is being removed.

struct scsi_target * **scsi_alloc_target**(struct device * parent, int channel, uint id)
allocate a new or find an existing target

Parameters

struct device * parent parent of the target (need not be a scsi host)

int channel target channel number (zero if no channels)

uint id target id number

Description

Return an existing target if one exists, provided it hasn't already gone into STARGET_DEL state, otherwise allocate a new target.

The target is returned with an incremented reference, so the caller is responsible for both reaping and doing a last put

void **scsi_target_reap**(struct scsi_target * starget)
check to see if target is in use and destroy if not

Parameters

struct scsi_target * starget target to be checked

Description

This is used after removing a LUN or doing a last put of the target it checks atomically that nothing is using the target and removes it if so.

int **scsi_probe_lun**(struct scsi_device * sdev, unsigned char * inq_result, int result_len, blist_flags_t * bflags)
probe a single LUN using a SCSI INQUIRY

Parameters

struct scsi_device * sdev scsi_device to probe

unsigned char * inq_result area to store the INQUIRY result

int result_len len of inq_result

blist_flags_t * bflags store any bflags found here

Description

Probe the lun associated with **req** using a standard SCSI INQUIRY;

If the INQUIRY is successful, zero is returned and the INQUIRY data is in **inq_result**; the scsi_level and INQUIRY length are copied to the scsi_device any flags value is stored in ***bflags**.

int **scsi_add_lun**(struct scsi_device * sdev, unsigned char * inq_result, blist_flags_t * bflags, int async)
allocate and fully initialze a scsi_device

Parameters

struct scsi_device * sdev holds information to be stored in the new scsi_device

unsigned char * inq_result holds the result of a previous INQUIRY to the LUN

blist_flags_t * bflags black/white list flag

int async 1 if this device is being scanned asynchronously

Description

Initialize the scsi_device **sdev**. Optionally set fields based on values in ***bflags**.

Return

SCSI_SCAN_NO_RESPONSE: could not allocate or setup a scsi_device SCSI_SCAN_LUN_PRESENT: a new scsi_device was allocated and initialized

unsigned char * **scsi_inq_str**(unsigned char * buf, unsigned char * inq, unsigned first, unsigned end)
print INQUIRY data from min to max index, strip trailing whitespace

Parameters

unsigned char * buf Output buffer with at least end-first+1 bytes of space

unsigned char * inq Inquiry buffer (input)

unsigned first Offset of string into inq

unsigned end Index after last character in inq

int **scsi_probe_and_add_lun**(struct scsi_target * starget, u64 lun, blist_flags_t * bflagsp, struct scsi_device ** sdevp, enum scsi_scan_mode rescan, void * hostdata)
probe a LUN, if a LUN is found add it

Parameters

struct scsi_target * starget pointer to target device structure

u64 lun LUN of target device

blist_flags_t * bflagsp store bflags here if not NULL

struct scsi_device ** sdevp probe the LUN corresponding to this scsi_device

enum scsi_scan_mode rescan if not equal to SCSI_SCAN_INITIAL skip some code only needed on first scan

void * hostdata passed to `scsi_alloc_sdev()`

Description

Call scsi_probe_lun, if a LUN with an attached device is found, allocate and set it up by calling scsi_add_lun.

Return

- SCSI_SCAN_NO_RESPONSE: could not allocate or setup a scsi_device
- **SCSI_SCAN_TARGET_PRESENT: target responded, but no device is** attached at the LUN
- SCSI_SCAN_LUN_PRESENT: a new scsi_device was allocated and initialized

void **scsi_sequential_lun_scan**(struct scsi_target * starget, blist_flags_t bflags, int scsi_level, enum scsi_scan_mode rescan)
sequentially scan a SCSI target

Parameters

struct scsi_target * starget pointer to target structure to scan

blist_flags_t bflags black/white list flag for LUN 0

int scsi_level Which version of the standard does this device adhere to

enum scsi_scan_mode rescan passed to scsi_probe_add_lun()

Description

Generally, scan from LUN 1 (LUN 0 is assumed to already have been scanned) to some maximum lun until a LUN is found with no device attached. Use the bflags to figure out any oddities.

Modifies sdevscan->lun.

int **scsi_report_lun_scan**(struct scsi_target * starget, blist_flags_t bflags, enum scsi_scan_mode rescan)
Scan using SCSI REPORT LUN results

Parameters

struct scsi_target * starget which target

blist_flags_t bflags Zero or a mix of BLIST_NOLUN, BLIST_REPORTLUN2, or BLIST_NOREPORTLUN

enum scsi_scan_mode rescan nonzero if we can skip code only needed on first scan

Description

Fast scanning for modern (SCSI-3) devices by sending a REPORT LUN command. Scan the resulting list of LUNs by calling scsi_probe_and_add_lun.

If BLINK_REPORTLUN2 is set, scan a target that supports more than 8 LUNs even if it's older than SCSI-3. If BLIST_NOREPORTLUN is set, return 1 always. If BLIST_NOLUN is set, return 0 always. If starget->no_report_luns is set, return 1 always.

Return

0: scan completed (or no memory, so further scanning is futile) 1: could not scan with REPORT LUN

struct async_scan_data * **scsi_prep_async_scan**(struct Scsi_Host * shost)
prepare for an async scan

Parameters

struct Scsi_Host * shost the host which will be scanned

Return

a cookie to be passed to `scsi_finish_async_scan()`

Description

Tells the midlayer this host is going to do an asynchronous scan. It reserves the host's position in the scanning list and ensures that other asynchronous scans started after this one won't affect the ordering of the discovered devices.

void **scsi_finish_async_scan**(struct async_scan_data * data)
asynchronous scan has finished

Parameters

struct async_scan_data * data cookie returned from earlier call to `scsi_prep_async_scan()`

Description

All the devices currently attached to this host have been found. This function announces all the devices it has found to the rest of the system.

drivers/scsi/scsi_sysctl.c

Set up the sysctl entry: "/dev/scsi/logging_level" (DEV_SCSI_LOGGING_LEVEL) which sets/returns scsi_logging_level.

drivers/scsi/scsi_sysfs.c

SCSI sysfs interface routines.

void **scsi_remove_device**(struct scsi_device * sdev)
unregister a device from the scsi bus

Parameters

struct scsi_device * sdev scsi_device to unregister

void **scsi_remove_target**(struct device * dev)
try to remove a target and all its devices

Parameters

struct device * dev generic starget or parent of generic stargets to be removed

Note

This is slightly racy. It is possible that if the user requests the addition of another device then the target won't be removed.

drivers/scsi/hosts.c

mid to lowlevel SCSI driver interface

void **scsi_remove_host**(struct Scsi_Host * shost)
remove a scsi host

Parameters

struct Scsi_Host * shost a pointer to a scsi host to remove

int **scsi_add_host_with_dma**(struct Scsi_Host * shost, struct device * dev, struct device * dma_dev)
add a scsi host with dma device

Parameters

struct Scsi_Host * shost scsi host pointer to add

struct device * dev a struct device of type scsi class

struct device * dma_dev dma device for the host

Note

You rarely need to worry about this unless you' re in a virtualised host environments, so use the simpler scsi_add_host() function instead.

Description

Return value: 0 on success / != 0 for error

struct Scsi_Host * **scsi_host_alloc**(struct scsi_host_template * sht, int privsize)
register a scsi host adapter instance.

Parameters

struct scsi_host_template * sht pointer to scsi host template

int privsize extra bytes to allocate for driver

Note

Allocate a new Scsi_Host and perform basic initialization. The host is not published to the scsi midlayer until scsi_add_host is called.

Description

Return value: Pointer to a new Scsi_Host

struct Scsi_Host * **scsi_host_lookup**(unsigned short hostnum)
get a reference to a Scsi_Host by host no

Parameters

unsigned short hostnum host number to locate

Description

Return value: A pointer to located Scsi_Host or NULL.

The caller must do a `scsi_host_put()` to drop the reference that `scsi_host_get()` took. The `put_device()` below dropped the reference from `class_find_device()`.

struct Scsi_Host * **scsi_host_get**(struct Scsi_Host * shost)
inc a Scsi_Host ref count

Parameters

struct Scsi_Host * shost Pointer to Scsi_Host to inc.

int **scsi_host_busy**(struct Scsi_Host * shost)
Return the host busy counter

Parameters

struct Scsi_Host * shost Pointer to Scsi_Host to inc.

void **scsi_host_put**(struct Scsi_Host * shost)
dec a Scsi_Host ref count

Parameters

struct Scsi_Host * shost Pointer to Scsi_Host to dec.

int **scsi_queue_work**(struct Scsi_Host * shost, struct work_struct * work)
Queue work to the Scsi_Host workqueue.

Parameters

struct Scsi_Host * shost Pointer to Scsi_Host.

struct work_struct * work Work to queue for execution.

Description

Return value: 1 - work queued for execution 0 - work is already queued -EINVAL - work queue doesn't exist

void **scsi_flush_work**(struct Scsi_Host * shost)
Flush a Scsi_Host's workqueue.

Parameters

struct Scsi_Host * shost Pointer to Scsi_Host.

void **scsi_host_complete_all_commands**(struct Scsi_Host * shost, int status)
Terminate all running commands

Parameters

struct Scsi_Host * shost Scsi Host on which commands should be terminated

int status Status to be set for the terminated commands

Description

There is no protection against modification of the number of outstanding commands. It is the responsibility of the caller to ensure that concurrent I/O submission and/or completion is stopped when calling this function.

void **scsi_host_busy_iter**(struct Scsi_Host * shost, bool (*fn)(struct scsi_cmnd *, void *, bool), void * priv)
Iterate over all busy commands

Parameters

struct Scsi_Host * shost Pointer to Scsi_Host.

bool (*)(struct scsi_cmnd *, void *, bool) fn Function to call on each busy command

void * priv Data pointer passed to **fn**

Description

If locking against concurrent command completions is required ithas to be provided by the caller

drivers/scsi/scsi_common.c

general support functions

const char * **scsi_device_type**(unsigned type)
Return 17-char string indicating device type.

Parameters

unsigned type type number to look up

u64 **scsilun_to_int**(struct scsi_lun * scsilun)
convert a scsi_lun to an int

Parameters

struct scsi_lun * scsilun struct scsi_lun to be converted.

Description

Convert **scsilun** from a struct scsi_lun to a four-byte host byte-ordered integer, and return the result. The caller must check for truncation before using this function.

Notes

For a description of the LUN format, post SCSI-3 see the SCSI Architecture Model, for SCSI-3 see the SCSI Controller Commands.

Given a struct scsi_lun of: d2 04 0b 03 00 00 00 00, this function returns the integer: 0x0b03d204

This encoding will return a standard integer LUN for LUNs smaller than 256, which typically use a single level LUN structure with addressing method 0.

void **int_to_scsilun**(u64 lun, struct scsi_lun * scsilun)
reverts an int into a scsi_lun

Parameters

u64 lun integer to be reverted

struct scsi_lun * scsilun struct scsi_lun to be set.

Description

Reverts the functionality of the scsilun_to_int, which packed an 8-byte lun value into an int. This routine unpacks the int back into the lun value.

Notes

Given an integer : 0x0b03d204, this function returns a struct scsi_lun of: d2 04 0b 03 00 00 00 00

bool **scsi_normalize_sense**(const u8 * sense_buffer, int sb_len, struct scsi_sense_hdr * sshdr)
normalize main elements from either fixed or descriptor sense data format into a common format.

Parameters

const u8 * sense_buffer byte array containing sense data returned by device

int sb_len number of valid bytes in sense_buffer

struct scsi_sense_hdr * sshdr pointer to instance of structure that common elements are written to.

Notes

The “main elements” from sense data are: response_code, sense_key, asc, ascq and additional_length (only for descriptor format).

Typically this function can be called after a device has responded to a SCSI command with the CHECK_CONDITION status.

Description

Return value: true if valid sense data information found, else false;

const u8 * **scsi_sense_desc_find**(const u8 * sense_buffer, int sb_len, int desc_type)
search for a given descriptor type in descriptor sense data format.

Parameters

const u8 * sense_buffer byte array of descriptor format sense data

int sb_len number of valid bytes in sense_buffer

int desc_type value of descriptor type to find (e.g. 0 -> information)

Notes

only valid when sense data is in descriptor format

Description

Return value: pointer to start of (first) descriptor if found else NULL

void **scsi_build_sense_buffer**(int desc, u8 * buf, u8 key, u8 asc, u8 ascq)
build sense data in a buffer

Parameters

int desc Sense format (non-zero == descriptor format, 0 == fixed format)

u8 * buf Where to build sense data

u8 key Sense key

u8 asc Additional sense code

u8 ascq Additional sense code qualifier

int **scsi_set_sense_information**(u8 * buf, int buf_len, u64 info)
set the information field in a formatted sense data buffer

Parameters

u8 * buf Where to build sense data

int buf_len buffer length

u64 info 64-bit information value to be set

Description

Return value: 0 on success or -EINVAL for invalid sense buffer length

int **scsi_set_sense_field_pointer**(u8 * buf, int buf_len, u16 fp, u8 bp, bool cd)
set the field pointer sense key specific information in a formatted sense data buffer

Parameters

u8 * buf Where to build sense data

int buf_len buffer length

u16 fp field pointer to be set

u8 bp bit pointer to be set

bool cd command/data bit

Description

Return value: 0 on success or -EINVAL for invalid sense buffer length

32.3.2 Transport classes

Transport classes are service libraries for drivers in the SCSI lower layer, which expose transport attributes in sysfs.

Fibre Channel transport

The file drivers/scsi/scsi_transport_fc.c defines transport attributes for Fibre Channel.

u32 **fc_get_event_number**(void)
Obtain the next sequential FC event number

Parameters

void no arguments

Notes

We could have inlined this, but it would have required fc_event_seq to be exposed. For now, live with the subroutine call. Atomic used to avoid lock/unlock…

void **fc_host_post_fc_event**(struct Scsi_Host * shost, u32 event_number, enum fc_host_event_code event_code, u32 data_len, char * data_buf, u64 vendor_id)

routine to do the work of posting an event on an fc_host.

Parameters

struct Scsi_Host * shost host the event occurred on

u32 event_number fc event number obtained from get_fc_event_number()

enum fc_host_event_code event_code fc_host event being posted

u32 data_len amount, in bytes, of event data

char * data_buf pointer to event data

u64 vendor_id value for Vendor id

Notes

This routine assumes no locks are held on entry.

void **fc_host_post_event**(struct Scsi_Host * shost, u32 event_number, enum fc_host_event_code event_code, u32 event_data)

called to post an even on an fc_host.

Parameters

struct Scsi_Host * shost host the event occurred on

u32 event_number fc event number obtained from get_fc_event_number()

enum fc_host_event_code event_code fc_host event being posted

u32 event_data 32bits of data for the event being posted

Notes

This routine assumes no locks are held on entry.

void **fc_host_post_vendor_event**(struct Scsi_Host * shost, u32 event_number, u32 data_len, char * data_buf, u64 vendor_id)

called to post a vendor unique event on an fc_host

Parameters

struct Scsi_Host * shost host the event occurred on

u32 event_number fc event number obtained from get_fc_event_number()

u32 data_len amount, in bytes, of vendor unique data

char * data_buf pointer to vendor unique data

u64 vendor_id Vendor id

Notes

This routine assumes no locks are held on entry.

void **fc_host_fpin_rcv**(struct Scsi_Host * shost, u32 fpin_len, char * fpin_buf)
routine to process a received FPIN.

Parameters

struct Scsi_Host * shost host the FPIN was received on

u32 fpin_len length of FPIN payload, in bytes

char * fpin_buf pointer to FPIN payload

Notes

This routine assumes no locks are held on entry.

enum blk_eh_timer_return **fc_eh_timed_out**(struct scsi_cmnd * scmd)
FC Transport I/O timeout intercept handler

Parameters

struct scsi_cmnd * scmd The SCSI command which timed out

Description

This routine protects against error handlers getting invoked while a rport is in a blocked state, typically due to a temporarily loss of connectivity. If the error handlers are allowed to proceed, requests to abort i/o, reset the target, etc will likely fail as there is no way to communicate with the device to perform the requested function. These failures may result in the midlayer taking the device offline, requiring manual intervention to restore operation.

This routine, called whenever an i/o times out, validates the state of the underlying rport. If the rport is blocked, it returns EH_RESET_TIMER, which will continue to reschedule the timeout. Eventually, either the device will return, or devloss_tmo will fire, and when the timeout then fires, it will be handled normally. If the rport is not blocked, normal error handling continues.

Notes

This routine assumes no locks are held on entry.

void **fc_remove_host**(struct Scsi_Host * shost)
called to terminate any fc_transport-related elements for a scsi host.

Parameters

struct Scsi_Host * shost Which `Scsi_Host`

Description

This routine is expected to be called immediately preceding the a driver's call to `scsi_remove_host()`.

WARNING: A driver utilizing the fc_transport, which fails to call this routine prior to `scsi_remove_host()`, will leave dangling objects in /sys/class/fc_remote_ports. Access to any of these objects can result in a system crash !!!

Notes

This routine assumes no locks are held on entry.

struct fc_rport * **fc_remote_port_add**(struct Scsi_Host * shost, int channel, struct fc_rport_identifiers * ids)
notify fc transport of the existence of a remote FC port.

Parameters

struct Scsi_Host * shost scsi host the remote port is connected to.

int channel Channel on shost port connected to.

struct fc_rport_identifiers * ids The world wide names, fc address, and FC4 port roles for the remote port.

Description

The LLDD calls this routine to notify the transport of the existence of a remote port. The LLDD provides the unique identifiers (wwpn,wwn) of the port, it's FC address (port_id), and the FC4 roles that are active for the port.

For ports that are FCP targets (aka scsi targets), the FC transport maintains consistent target id bindings on behalf of the LLDD. A consistent target id binding is an assignment of a target id to a remote port identifier, which persists while the scsi host is attached. The remote port can disappear, then later reappear, and it's target id assignment remains the same. This allows for shifts in FC addressing (if binding by wwpn or wwnn) with no apparent changes to the scsi subsystem which is based on scsi host number and target id values. Bindings are only valid during the attachment of the scsi host. If the host detaches, then later re-attaches, target id bindings may change.

This routine is responsible for returning a remote port structure. The routine will search the list of remote ports it maintains internally on behalf of consistent target id mappings. If found, the remote port structure will be reused. Otherwise, a new remote port structure will be allocated.

Whenever a remote port is allocated, a new fc_remote_port class device is created.

Should not be called from interrupt context.

Notes

This routine assumes no locks are held on entry.

void **fc_remote_port_delete**(struct fc_rport * rport)
notifies the fc transport that a remote port is no longer in existence.

Parameters

struct fc_rport * rport The remote port that no longer exists

Description

The LLDD calls this routine to notify the transport that a remote port is no longer part of the topology. Note: Although a port may no longer be part of the topology, it may persist in the remote ports displayed by the fc_host. We do this under 2 conditions:

1) If the port was a scsi target, we delay its deletion by "blocking" it. This allows the port to temporarily disappear, then reappear without disrupting the SCSI device tree attached to it. During the "blocked" period the port will still exist.

2) If the port was a scsi target and disappears for longer than we expect, we'll delete the port and the tear down the SCSI device tree attached to it. However, we want to semi-persist the target id assigned to that port if it eventually does exist. The port structure will remain (although with minimal information) so that the target id bindings also remain.

If the remote port is not an FCP Target, it will be fully torn down and deallocated, including the fc_remote_port class device.

If the remote port is an FCP Target, the port will be placed in a temporary blocked state. From the LLDD's perspective, the rport no longer exists. From the SCSI midlayer's perspective, the SCSI target exists, but all sdevs on it are blocked from further I/O. The following is then expected.

If the remote port does not return (signaled by a LLDD call to `fc_remote_port_add()`) within the dev_loss_tmo timeout, then the scsi target is removed - killing all outstanding i/o and removing the scsi devices attached to it. The port structure will be marked Not Present and be partially cleared, leaving only enough information to recognize the remote port relative to the scsi target id binding if it later appears. The port will remain as long as there is a valid binding (e.g. until the user changes the binding type or unloads the scsi host with the binding).

If the remote port returns within the dev_loss_tmo value (and matches according to the target id binding type), the port structure will be reused. If it is no longer a SCSI target, the target will be torn down. If it continues to be a SCSI target, then the target will be unblocked (allowing i/o to be resumed), and a scan will be activated to ensure that all luns are detected.

Called from normal process context only - cannot be called from interrupt.

Notes

This routine assumes no locks are held on entry.

void **fc_remote_port_rolechg**(struct fc_rport * rport, u32 roles)
notifies the fc transport that the roles on a remote may have changed.

Parameters

struct fc_rport * rport The remote port that changed.

u32 roles New roles for this port.

Description

The LLDD calls this routine to notify the transport that the roles on a remote port may have changed. The largest effect of this is if a port now becomes a FCP Target, it must be allocated a scsi target id. If the port is no longer a FCP target, any scsi target id value assigned to it will persist in case the role changes back to include FCP Target. No changes in the scsi midlayer will be invoked if the role changes (in the expectation that the role will be resumed. If it doesn't normal error processing will take place).

Should not be called from interrupt context.

Notes

This routine assumes no locks are held on entry.

int **fc_block_rport**(struct fc_rport * rport)
Block SCSI eh thread for blocked fc_rport.

Parameters

struct fc_rport * rport Remote port that scsi_eh is trying to recover.

Description

This routine can be called from a FC LLD scsi_eh callback. It blocks the scsi_eh thread until the fc_rport leaves the FC_PORTSTATE_BLOCKED, or the fast_io_fail_tmo fires. This is necessary to avoid the scsi_eh failing recovery actions for blocked rports which would lead to offlined SCSI devices.

Return

0 if the fc_rport left the state FC_PORTSTATE_BLOCKED. FAST_IO_FAIL if the fast_io_fail_tmo fired, this should be passed back to scsi_eh.

int **fc_block_scsi_eh**(struct scsi_cmnd * cmnd)
Block SCSI eh thread for blocked fc_rport

Parameters

struct scsi_cmnd * cmnd SCSI command that scsi_eh is trying to recover

Description

This routine can be called from a FC LLD scsi_eh callback. It blocks the scsi_eh thread until the fc_rport leaves the FC_PORTSTATE_BLOCKED, or the fast_io_fail_tmo fires. This is necessary to avoid the scsi_eh failing recovery actions for blocked rports which would lead to offlined SCSI devices.

Return

0 if the fc_rport left the state FC_PORTSTATE_BLOCKED. FAST_IO_FAIL if the fast_io_fail_tmo fired, this should be passed back to scsi_eh.

struct fc_vport * **fc_vport_create**(struct Scsi_Host * shost, int channel,
struct fc_vport_identifiers * ids)
Admin App or LLDD requests creation of a vport

Parameters

struct Scsi_Host * shost scsi host the virtual port is connected to.

int channel channel on shost port connected to.

struct fc_vport_identifiers * ids The world wide names, FC4 port roles, etc for the virtual port.

Notes

This routine assumes no locks are held on entry.

int **fc_vport_terminate**(struct fc_vport * vport)
Admin App or LLDD requests termination of a vport

Parameters

struct fc_vport * vport fc_vport to be terminated

Description

Calls the LLDD vport_delete() function, then deallocates and removes the vport from the shost and object tree.

Notes

This routine assumes no locks are held on entry.

iSCSI transport class

The file drivers/scsi/scsi_transport_iscsi.c defines transport attributes for the iSCSI class, which sends SCSI packets over TCP/IP connections.

struct iscsi_bus_flash_session * **iscsi_create_flashnode_sess**(struct Scsi_Host * shost, int index, struct iscsi_transport * transport, int dd_size)

Add flashnode session entry in sysfs

Parameters

struct Scsi_Host * shost pointer to host data

int index index of flashnode to add in sysfs

struct iscsi_transport * transport pointer to transport data

int dd_size total size to allocate

Description

Adds a sysfs entry for the flashnode session attributes

Return

pointer to allocated flashnode sess on success NULL on failure

struct iscsi_bus_flash_conn * **iscsi_create_flashnode_conn**(struct Scsi_Host * shost, struct iscsi_bus_flash_session * fnode_sess, struct iscsi_transport * transport, int dd_size)

Add flashnode conn entry in sysfs

Parameters

struct Scsi_Host * shost pointer to host data

struct iscsi_bus_flash_session * fnode_sess pointer to the parent flashnode session entry

struct iscsi_transport * transport pointer to transport data

int dd_size total size to allocate

Description

Adds a sysfs entry for the flashnode connection attributes

Return

pointer to allocated flashnode conn on success NULL on failure

struct device * **iscsi_find_flashnode_sess**(struct Scsi_Host * shost, void * data, int (*fn)(struct device *dev, void *data))

finds flashnode session entry

Parameters

struct Scsi_Host * shost pointer to host data

void * data pointer to data containing value to use for comparison

int (*)(struct device *dev, void *data) fn function pointer that does actual comparison

Description

Finds the flashnode session object comparing the data passed using logic defined in passed function pointer

Return

pointer to found flashnode session device object on success NULL on failure

struct device * **iscsi_find_flashnode_conn**(struct iscsi_bus_flash_session * fnode_sess)

finds flashnode connection entry

Parameters

struct iscsi_bus_flash_session * fnode_sess pointer to parent flashnode session entry

Description

Finds the flashnode connection object comparing the data passed using logic defined in passed function pointer

Return

pointer to found flashnode connection device object on success NULL on failure

void **iscsi_destroy_flashnode_sess**(struct iscsi_bus_flash_session * fnode_sess)

destroy flashnode session entry

Parameters

struct iscsi_bus_flash_session * fnode_sess pointer to flashnode session entry to be destroyed

Description

Deletes the flashnode session entry and all children flashnode connection entries from sysfs

void **iscsi_destroy_all_flashnode**(struct Scsi_Host * shost)
destroy all flashnode session entries

Parameters

struct Scsi_Host * shost pointer to host data

Description

Destroys all the flashnode session entries and all corresponding children flashnode connection entries from sysfs

int **iscsi_scan_finished**(struct Scsi_Host * shost, unsigned long time)
helper to report when running scans are done

Parameters

struct Scsi_Host * shost scsi host

unsigned long time scan run time

Description

This function can be used by drives like qla4xxx to report to the scsi layer when the scans it kicked off at module load time are done.

int **iscsi_block_scsi_eh**(struct scsi_cmnd * cmd)
block scsi eh until session state has transistioned

Parameters

struct scsi_cmnd * cmd scsi cmd passed to scsi eh handler

Description

If the session is down this function will wait for the recovery timer to fire or for the session to be logged back in. If the recovery timer fires then FAST_IO_FAIL is returned. The caller should pass this error value to the scsi eh.

void **iscsi_unblock_session**(struct iscsi_cls_session * session)
set a session as logged in and start IO.

Parameters

struct iscsi_cls_session * session iscsi session

Description

Mark a session as ready to accept IO.

struct iscsi_cls_session * **iscsi_create_session**(struct Scsi_Host * shost, struct iscsi_transport * transport, int dd_size, unsigned int target_id)
create iscsi class session

Parameters

struct Scsi_Host * shost scsi host

struct iscsi_transport * transport iscsi transport

int dd_size private driver data size

unsigned int target_id which target

Description

This can be called from a LLD or iscsi_transport.

struct iscsi_cls_conn * **iscsi_create_conn**(struct iscsi_cls_session * session, int dd_size, uint32_t cid)
create iscsi class connection

Parameters

struct iscsi_cls_session * session iscsi cls session

int dd_size private driver data size

uint32_t cid connection id

Description

This can be called from a LLD or iscsi_transport. The connection is child of the session so cid must be unique for all connections on the session.

Since we do not support MCS, cid will normally be zero. In some cases for software iscsi we could be trying to preallocate a connection struct in which case there could be two connection structs and cid would be non-zero.

int **iscsi_destroy_conn**(struct iscsi_cls_conn * conn)
destroy iscsi class connection

Parameters

struct iscsi_cls_conn * conn iscsi cls session

Description

This can be called from a LLD or iscsi_transport.

int **iscsi_session_event**(struct iscsi_cls_session * session, enum iscsi_uevent_e event)
send session destr. completion event

Parameters

struct iscsi_cls_session * session iscsi class session

enum iscsi_uevent_e event type of event

Serial Attached SCSI (SAS) transport class

The file drivers/scsi/scsi_transport_sas.c defines transport attributes for Serial Attached SCSI, a variant of SATA aimed at large high-end systems.

The SAS transport class contains common code to deal with SAS HBAs, an aproximated representation of SAS topologies in the driver model, and various sysfs attributes to expose these topologies and management interfaces to userspace.

In addition to the basic SCSI core objects this transport class introduces two additional intermediate objects: The SAS PHY as represented by struct sas_phy defines an "outgoing" PHY on a SAS HBA or Expander, and the SAS remote PHY represented by struct sas_rphy defines an "incoming" PHY on a SAS Expander or end device. Note that this is purely a software concept, the underlying hardware for a PHY and a remote PHY is the exactly the same.

There is no concept of a SAS port in this code, users can see what PHYs form a wide port based on the port_identifier attribute, which is the same for all PHYs in a port.

void **sas_remove_children**(struct device * dev)
tear down a devices SAS data structures

Parameters

struct device * dev device belonging to the sas object

Description

Removes all SAS PHYs and remote PHYs for a given object

void **sas_remove_host**(struct Scsi_Host * shost)
tear down a Scsi_Host's SAS data structures

Parameters

struct Scsi_Host * shost Scsi Host that is torn down

Description

Removes all SAS PHYs and remote PHYs for a given Scsi_Host and remove the Scsi_Host as well.

Note

Do not call `scsi_remove_host()` on the Scsi_Host any more, as it is already removed.

u64 **sas_get_address**(struct scsi_device * sdev)
return the SAS address of the device

Parameters

struct scsi_device * sdev scsi device

Description

Returns the SAS address of the scsi device

unsigned int **sas_tlr_supported**(struct scsi_device * sdev)
checking TLR bit in vpd 0x90

Parameters

struct scsi_device * sdev scsi device struct

Description

Check Transport Layer Retries are supported or not. If vpd page 0x90 is present, TRL is supported.

void **sas_disable_tlr**(struct scsi_device * sdev)
setting TLR flags

Parameters

struct scsi_device * sdev scsi device struct

Description

Seting tlr_enabled flag to 0.

void **sas_enable_tlr**(struct scsi_device * sdev)
setting TLR flags

Parameters

struct scsi_device * sdev scsi device struct

Description

Seting tlr_enabled flag 1.

struct sas_phy * **sas_phy_alloc**(struct device * parent, int number)
allocates and initialize a SAS PHY structure

Parameters

struct device * parent Parent device

int number Phy index

Description

Allocates an SAS PHY structure. It will be added in the device tree below the device specified by **parent**, which has to be either a Scsi_Host or sas_rphy.

Return

SAS PHY allocated or `NULL` if the allocation failed.

int **sas_phy_add**(struct sas_phy * phy)
add a SAS PHY to the device hierarchy

Parameters

struct sas_phy * phy The PHY to be added

Description

Publishes a SAS PHY to the rest of the system.

void **sas_phy_free**(struct sas_phy * phy)
free a SAS PHY

Parameters

struct sas_phy * phy SAS PHY to free

Description

Frees the specified SAS PHY.

Note

This function must only be called on a PHY that has not successfully been added using `sas_phy_add()`.

void **sas_phy_delete**(struct sas_phy * phy)
remove SAS PHY

Parameters

struct sas_phy * phy SAS PHY to remove

Description

Removes the specified SAS PHY. If the SAS PHY has an associated remote PHY it is removed before.

int **scsi_is_sas_phy**(const struct device * dev)
check if a struct device represents a SAS PHY

Parameters

const struct device * dev device to check

Return

`1` if the device represents a SAS PHY, `0` else

int **sas_port_add**(struct sas_port * port)
add a SAS port to the device hierarchy

Parameters

struct sas_port * port port to be added

Description

publishes a port to the rest of the system

void **sas_port_free**(struct sas_port * port)
free a SAS PORT

Parameters

struct sas_port * port SAS PORT to free

Description

Frees the specified SAS PORT.

Note

This function must only be called on a PORT that has not successfully been added using `sas_port_add()`.

void **sas_port_delete**(struct sas_port * port)
remove SAS PORT

Parameters

struct sas_port * port SAS PORT to remove

Description

Removes the specified SAS PORT. If the SAS PORT has an associated phys, unlink them from the port as well.

int **scsi_is_sas_port**(const struct device * dev)
check if a struct device represents a SAS port

Parameters

const struct device * dev device to check

Return

1 if the device represents a SAS Port, 0 else

struct sas_phy * **sas_port_get_phy**(struct sas_port * port)
try to take a reference on a port member

Parameters

struct sas_port * port port to check

void **sas_port_add_phy**(struct sas_port * port, struct sas_phy * phy)
add another phy to a port to form a wide port

Parameters

struct sas_port * port port to add the phy to

struct sas_phy * phy phy to add

Description

When a port is initially created, it is empty (has no phys). All ports must have at least one phy to operated, and all wide ports must have at least two. The current code makes no difference between ports and wide ports, but the only object that can be connected to a remote device is a port, so ports must be formed on all devices with phys if they' re connected to anything.

void **sas_port_delete_phy**(struct sas_port * port, struct sas_phy * phy)
remove a phy from a port or wide port

Parameters

struct sas_port * port port to remove the phy from

struct sas_phy * phy phy to remove

Description

This operation is used for tearing down ports again. It must be done to every port or wide port before calling sas_port_delete.

struct sas_rphy * **sas_end_device_alloc**(struct sas_port * parent)
allocate an rphy for an end device

Parameters

struct sas_port * parent which port

Description

Allocates an SAS remote PHY structure, connected to **parent**.

Return

SAS PHY allocated or `NULL` if the allocation failed.

struct sas_rphy * **sas_expander_alloc**(struct sas_port * parent, enum sas_device_type type)
allocate an rphy for an end device

Parameters

struct sas_port * parent which port

enum sas_device_type type SAS_EDGE_EXPANDER_DEVICE or SAS_FANOUT_EXPANDER_DEVICE

Description

Allocates an SAS remote PHY structure, connected to **parent**.

Return

SAS PHY allocated or `NULL` if the allocation failed.

int **sas_rphy_add**(struct sas_rphy * rphy)
add a SAS remote PHY to the device hierarchy

Parameters

struct sas_rphy * rphy The remote PHY to be added

Description

Publishes a SAS remote PHY to the rest of the system.

void **sas_rphy_free**(struct sas_rphy * rphy)
free a SAS remote PHY

Parameters

struct sas_rphy * rphy SAS remote PHY to free

Description

Frees the specified SAS remote PHY.

Note

This function must only be called on a remote PHY that has not successfully been added using `sas_rphy_add()` (or has been `sas_rphy_remove()`' d)

void **sas_rphy_delete**(struct sas_rphy * rphy)
remove and free SAS remote PHY

Parameters

struct sas_rphy * rphy SAS remote PHY to remove and free

Description

Removes the specified SAS remote PHY and frees it.

void **sas_rphy_unlink**(struct sas_rphy * rphy)
unlink SAS remote PHY

Parameters

struct sas_rphy * rphy SAS remote phy to unlink from its parent port

Description

Removes port reference to an rphy

void **sas_rphy_remove**(struct sas_rphy * rphy)
remove SAS remote PHY

Parameters

struct sas_rphy * rphy SAS remote phy to remove

Description

Removes the specified SAS remote PHY.

int **scsi_is_sas_rphy**(const struct device * dev)
check if a struct device represents a SAS remote PHY

Parameters

const struct device * dev device to check

Return

1 if the device represents a SAS remote PHY, 0 else

struct scsi_transport_template * **sas_attach_transport**(struct sas_function_template * ft)
instantiate SAS transport template

Parameters

struct sas_function_template * ft SAS transport class function template

void **sas_release_transport**(struct scsi_transport_template * t)
release SAS transport template instance

Parameters

struct scsi_transport_template * t transport template instance

SATA transport class

The SATA transport is handled by libata, which has its own book of documentation in this directory.

Parallel SCSI (SPI) transport class

The file drivers/scsi/scsi_transport_spi.c defines transport attributes for traditional (fast/wide/ultra) SCSI busses.

void **spi_schedule_dv_device**(struct scsi_device * sdev)
schedule domain validation to occur on the device

Parameters

struct scsi_device * sdev The device to validate

Identical to spi_dv_device() above, except that the DV will be scheduled to occur in a workqueue later. All memory allocations are atomic, so may be called from any context including those holding SCSI locks.

void **spi_display_xfer_agreement**(struct scsi_target * starget)
Print the current target transfer agreement

Parameters

struct scsi_target * starget The target for which to display the agreement

Description

Each SPI port is required to maintain a transfer agreement for each other port on the bus. This function prints a one-line summary of the current agreement; more detailed information is available in sysfs.

int **spi_populate_tag_msg**(unsigned char * msg, struct scsi_cmnd * cmd)
place a tag message in a buffer

Parameters

unsigned char * msg pointer to the area to place the tag

struct scsi_cmnd * cmd pointer to the scsi command for the tag

Notes

designed to create the correct type of tag message for the particular request. Returns the size of the tag message. May return 0 if TCQ is disabled for this device.

SCSI RDMA (SRP) transport class

The file drivers/scsi/scsi_transport_srp.c defines transport attributes for SCSI over Remote Direct Memory Access.

int **srp_tmo_valid**(int reconnect_delay, int fast_io_fail_tmo,
long dev_loss_tmo)
check timeout combination validity

Parameters

int reconnect_delay Reconnect delay in seconds.

int fast_io_fail_tmo Fast I/O fail timeout in seconds.

long dev_loss_tmo Device loss timeout in seconds.

Description

The combination of the timeout parameters must be such that SCSI commands are finished in a reasonable time. Hence do not allow the fast I/O fail timeout to exceed SCSI_DEVICE_BLOCK_MAX_TIMEOUT nor allow dev_loss_tmo to exceed that limit if failing I/O fast has been disabled. Furthermore, these parameters must be such that multipath can detect failed paths timely. Hence do not allow all three parameters to be disabled simultaneously.

void **srp_start_tl_fail_timers**(struct srp_rport * rport)
start the transport layer failure timers

Parameters

struct srp_rport * rport SRP target port.

Description

Start the transport layer fast I/O failure and device loss timers. Do not modify a timer that was already started.

int **srp_reconnect_rport**(struct srp_rport * rport)
reconnect to an SRP target port

Parameters

struct srp_rport * rport SRP target port.

Description

Blocks SCSI command queueing before invoking reconnect() such that queuecommand() won't be invoked concurrently with reconnect() from outside the SCSI EH. This is important since a reconnect() implementation may reallocate resources needed by queuecommand().

Notes

- This function neither waits until outstanding requests have finished nor tries to abort these. It is the responsibility of the reconnect() function to finish outstanding commands before reconnecting to the target port.
- It is the responsibility of the caller to ensure that the resources reallocated by the reconnect() function won't be used while this function is in progress. One possible strategy is to invoke this function from the context of the SCSI EH thread only. Another possible strategy is to lock the rport mutex inside each SCSI LLD callback that can be invoked by the SCSI EH (the scsi_host_template.eh_*() functions and also the scsi_host_template.queuecommand() function).

enum blk_eh_timer_return **srp_timed_out**(struct scsi_cmnd * scmd)
SRP transport intercept of the SCSI timeout EH

Parameters

struct scsi_cmnd * scmd SCSI command.

Description

If a timeout occurs while an rport is in the blocked state, ask the SCSI EH to continue waiting (BLK_EH_RESET_TIMER). Otherwise let the SCSI core handle the timeout (BLK_EH_DONE).

Note

This function is called from soft-IRQ context and with the request queue lock held.

void **srp_rport_get**(struct srp_rport * rport)
increment rport reference count

Parameters

struct srp_rport * rport SRP target port.

void **srp_rport_put**(struct srp_rport * rport)
decrement rport reference count

Parameters

struct srp_rport * rport SRP target port.

struct srp_rport * **srp_rport_add**(struct Scsi_Host * shost, struct srp_rport_identifiers * ids)
add a SRP remote port to the device hierarchy

Parameters

struct Scsi_Host * shost scsi host the remote port is connected to.

struct srp_rport_identifiers * ids The port id for the remote port.

Description

Publishes a port to the rest of the system.

void **srp_rport_del**(struct srp_rport * rport)
remove a SRP remote port

Parameters

struct srp_rport * rport SRP remote port to remove

Description

Removes the specified SRP remote port.

void **srp_remove_host**(struct Scsi_Host * shost)
tear down a Scsi_Host's SRP data structures

Parameters

struct Scsi_Host * shost Scsi Host that is torn down

Description

Removes all SRP remote ports for a given Scsi_Host. Must be called just before scsi_remove_host for SRP HBAs.

void **srp_stop_rport_timers**(struct srp_rport * rport)
stop the transport layer recovery timers

Parameters

struct srp_rport * rport SRP remote port for which to stop the timers.

Description

Must be called after `srp_remove_host()` and `scsi_remove_host()`. The caller must hold a reference on the rport (rport->dev) and on the SCSI host (rport->dev.parent).

struct scsi_transport_template * **srp_attach_transport**(struct srp_function_template * ft)
instantiate SRP transport template

Parameters

struct srp_function_template * ft SRP transport class function template

void **srp_release_transport**(struct scsi_transport_template * t)
release SRP transport template instance

Parameters

struct scsi_transport_template * t transport template instance

32.4 SCSI lower layer

32.4.1 Host Bus Adapter transport types

Many modern device controllers use the SCSI command set as a protocol to communicate with their devices through many different types of physical connections.

In SCSI language a bus capable of carrying SCSI commands is called a “transport”, and a controller connecting to such a bus is called a “host bus adapter” (HBA).

Debug transport

The file drivers/scsi/scsi_debug.c simulates a host adapter with a variable number of disks (or disk like devices) attached, sharing a common amount of RAM. Does a lot of checking to make sure that we are not getting blocks mixed up, and panics the kernel if anything out of the ordinary is seen.

To be more realistic, the simulated devices have the transport attributes of SAS disks.

For documentation see http://sg.danny.cz/sg/sdebug26.html

CHAPTER

THIRTYTHREE

LIBATA DEVELOPER'S GUIDE

Author Jeff Garzik

33.1 Introduction

libATA is a library used inside the Linux kernel to support ATA host controllers and devices. libATA provides an ATA driver API, class transports for ATA and ATAPI devices, and SCSI<->ATA translation for ATA devices according to the T10 SAT specification.

This Guide documents the libATA driver API, library functions, library internals, and a couple sample ATA low-level drivers.

33.2 libata Driver API

`struct ata_port_operations` is defined for every low-level libata hardware driver, and it controls how the low-level driver interfaces with the ATA and SCSI layers.

FIS-based drivers will hook into the system with `->qc_prep()` and `->qc_issue()` high-level hooks. Hardware which behaves in a manner similar to PCI IDE hardware may utilize several generic helpers, defining at a bare minimum the bus I/O addresses of the ATA shadow register blocks.

33.2.1 `struct ata_port_operations`

Disable ATA port

```
void (*port_disable) (struct ata_port *);
```

Called from `ata_bus_probe()` error path, as well as when unregistering from the SCSI module (rmmod, hot unplug). This function should do whatever needs to be done to take the port out of use. In most cases, `ata_port_disable()` can be used as this hook.

Called from `ata_bus_probe()` on a failed probe. Called from `ata_scsi_release()`.

Post-IDENTIFY device configuration

```
void (*dev_config) (struct ata_port *, struct ata_device *);
```

Called after IDENTIFY [PACKET] DEVICE is issued to each device found. Typically used to apply device-specific fixups prior to issue of SET FEATURES - XFER MODE, and prior to operation.

This entry may be specified as NULL in ata_port_operations.

Set PIO/DMA mode

```
void (*set_piomode) (struct ata_port *, struct ata_device *);
void (*set_dmamode) (struct ata_port *, struct ata_device *);
void (*post_set_mode) (struct ata_port *);
unsigned int (*mode_filter) (struct ata_port *, struct ata_device *,␣
↪unsigned int);
```

Hooks called prior to the issue of SET FEATURES - XFER MODE command. The optional `->mode_filter()` hook is called when libata has built a mask of the possible modes. This is passed to the `->mode_filter()` function which should return a mask of valid modes after filtering those unsuitable due to hardware limits. It is not valid to use this interface to add modes.

`dev->pio_mode` and `dev->dma_mode` are guaranteed to be valid when `->set_piomode()` and when `->set_dmamode()` is called. The timings for any other drive sharing the cable will also be valid at this point. That is the library records the decisions for the modes of each drive on a channel before it attempts to set any of them.

`->post_set_mode()` is called unconditionally, after the SET FEATURES - XFER MODE command completes successfully.

`->set_piomode()` is always called (if present), but `->set_dma_mode()` is only called if DMA is possible.

Taskfile read/write

```
void (*sff_tf_load) (struct ata_port *ap, struct ata_taskfile *tf);
void (*sff_tf_read) (struct ata_port *ap, struct ata_taskfile *tf);
```

`->tf_load()` is called to load the given taskfile into hardware registers / DMA buffers. `->tf_read()` is called to read the hardware registers / DMA buffers, to obtain the current set of taskfile register values. Most drivers for taskfile-based hardware (PIO or MMIO) use `ata_sff_tf_load()` and `ata_sff_tf_read()` for these hooks.

PIO data read/write

```
void (*sff_data_xfer) (struct ata_device *, unsigned char *, unsigned int,␣
↪int);
```

All bmdma-style drivers must implement this hook. This is the low-level operation that actually copies the data bytes during a PIO data transfer. Typically the driver will choose one of `ata_sff_data_xfer()`, or `ata_sff_data_xfer32()`.

ATA command execute

```
void (*sff_exec_command)(struct ata_port *ap, struct ata_taskfile *tf);
```

causes an ATA command, previously loaded with `->tf_load()`, to be initiated in hardware. Most drivers for taskfile-based hardware use `ata_sff_exec_command()` for this hook.

Per-cmd ATAPI DMA capabilities filter

```
int (*check_atapi_dma) (struct ata_queued_cmd *qc);
```

Allow low-level driver to filter ATA PACKET commands, returning a status indicating whether or not it is OK to use DMA for the supplied PACKET command.

This hook may be specified as NULL, in which case libata will assume that atapi dma can be supported.

Read specific ATA shadow registers

```
u8   (*sff_check_status)(struct ata_port *ap);
u8   (*sff_check_altstatus)(struct ata_port *ap);
```

Reads the Status/AltStatus ATA shadow register from hardware. On some hardware, reading the Status register has the side effect of clearing the interrupt condition. Most drivers for taskfile-based hardware use `ata_sff_check_status()` for this hook.

Write specific ATA shadow register

```
void (*sff_set_devctl)(struct ata_port *ap, u8 ctl);
```

Write the device control ATA shadow register to the hardware. Most drivers don't need to define this.

Select ATA device on bus

```
void (*sff_dev_select)(struct ata_port *ap, unsigned int device);
```

Issues the low-level hardware command(s) that causes one of N hardware devices to be considered 'selected' (active and available for use) on the ATA bus. This generally has no meaning on FIS-based devices.

Most drivers for taskfile-based hardware use `ata_sff_dev_select()` for this hook.

Private tuning method

```
void (*set_mode) (struct ata_port *ap);
```

By default libata performs drive and controller tuning in accordance with the ATA timing rules and also applies blacklists and cable limits. Some controllers need special handling and have custom tuning rules, typically raid controllers that use ATA commands but do not actually do drive timing.

> **Warning**
>
> This hook should not be used to replace the standard controller tuning logic when a controller has quirks. Replacing the default tuning logic in that case would bypass handling for drive and bridge quirks that may be important to data reliability. If a controller needs to filter the mode selection it should use the mode_filter hook instead.

Control PCI IDE BMDMA engine

```
void (*bmdma_setup) (struct ata_queued_cmd *qc);
void (*bmdma_start) (struct ata_queued_cmd *qc);
void (*bmdma_stop) (struct ata_port *ap);
u8   (*bmdma_status) (struct ata_port *ap);
```

When setting up an IDE BMDMA transaction, these hooks arm (`->bmdma_setup`), fire (`->bmdma_start`), and halt (`->bmdma_stop`) the hardware's DMA engine. `->bmdma_status` is used to read the standard PCI IDE DMA Status register.

These hooks are typically either no-ops, or simply not implemented, in FIS-based drivers.

Most legacy IDE drivers use `ata_bmdma_setup()` for the `bmdma_setup()` hook. `ata_bmdma_setup()` will write the pointer to the PRD table to the IDE PRD Table Address register, enable DMA in the DMA Command register, and call `exec_command()` to begin the transfer.

Most legacy IDE drivers use `ata_bmdma_start()` for the `bmdma_start()` hook. `ata_bmdma_start()` will write the ATA_DMA_START flag to the DMA Command register.

Many legacy IDE drivers use `ata_bmdma_stop()` for the `bmdma_stop()` hook. `ata_bmdma_stop()` clears the ATA_DMA_START flag in the DMA command register.

Many legacy IDE drivers use ata_bmdma_status() as the bmdma_status() hook.

High-level taskfile hooks

```
enum ata_completion_errors (*qc_prep) (struct ata_queued_cmd *qc);
int (*qc_issue) (struct ata_queued_cmd *qc);
```

Higher-level hooks, these two hooks can potentially supersede several of the above taskfile/DMA engine hooks. ->qc_prep is called after the buffers have been DMA-mapped, and is typically used to populate the hardware's DMA scatter-gather table. Some drivers use the standard ata_bmdma_qc_prep() and ata_bmdma_dumb_qc_prep() helper functions, but more advanced drivers roll their own.

->qc_issue is used to make a command active, once the hardware and S/G tables have been prepared. IDE BMDMA drivers use the helper function ata_sff_qc_issue() for taskfile protocol-based dispatch. More advanced drivers implement their own ->qc_issue.

ata_sff_qc_issue() calls ->sff_tf_load(), ->bmdma_setup(), and ->bmdma_start() as necessary to initiate a transfer.

Exception and probe handling (EH)

```
void (*eng_timeout) (struct ata_port *ap);
void (*phy_reset) (struct ata_port *ap);
```

Deprecated. Use ->error_handler() instead.

```
void (*freeze) (struct ata_port *ap);
void (*thaw) (struct ata_port *ap);
```

ata_port_freeze() is called when HSM violations or some other condition disrupts normal operation of the port. A frozen port is not allowed to perform any operation until the port is thawed, which usually follows a successful reset.

The optional ->freeze() callback can be used for freezing the port hardware-wise (e.g. mask interrupt and stop DMA engine). If a port cannot be frozen hardware-wise, the interrupt handler must ack and clear interrupts unconditionally while the port is frozen.

The optional ->thaw() callback is called to perform the opposite of ->freeze(): prepare the port for normal operation once again. Unmask interrupts, start DMA engine, etc.

```
void (*error_handler) (struct ata_port *ap);
```

->error_handler() is a driver's hook into probe, hotplug, and recovery and other exceptional conditions. The primary responsibility of an implementation is to call ata_do_eh() or ata_bmdma_drive_eh() with a set of EH hooks as arguments:

'prereset' hook (may be NULL) is called during an EH reset, before any other actions are taken.

'postreset' hook (may be NULL) is called after the EH reset is performed. Based on existing conditions, severity of the problem, and hardware capabilities,

Either 'softreset' (may be NULL) or 'hardreset' (may be NULL) will be called to perform the low-level EH reset.

```
void (*post_internal_cmd) (struct ata_queued_cmd *qc);
```

Perform any hardware-specific actions necessary to finish processing after executing a probe-time or EH-time command via `ata_exec_internal()`.

Hardware interrupt handling

```
irqreturn_t (*irq_handler)(int, void *, struct pt_regs *);
void (*irq_clear) (struct ata_port *);
```

`->irq_handler` is the interrupt handling routine registered with the system, by libata. `->irq_clear` is called during probe just before the interrupt handler is registered, to be sure hardware is quiet.

The second argument, dev_instance, should be cast to a pointer to `struct ata_host_set`.

Most legacy IDE drivers use `ata_sff_interrupt()` for the irq_handler hook, which scans all ports in the host_set, determines which queued command was active (if any), and calls ata_sff_host_intr(ap,qc).

Most legacy IDE drivers use `ata_sff_irq_clear()` for the `irq_clear()` hook, which simply clears the interrupt and error flags in the DMA status register.

SATA phy read/write

```
int (*scr_read) (struct ata_port *ap, unsigned int sc_reg,
         u32 *val);
int (*scr_write) (struct ata_port *ap, unsigned int sc_reg,
                  u32 val);
```

Read and write standard SATA phy registers. Currently only used if `->phy_reset` hook called the `sata_phy_reset()` helper function. sc_reg is one of SCR_STATUS, SCR_CONTROL, SCR_ERROR, or SCR_ACTIVE.

Init and shutdown

```
int (*port_start) (struct ata_port *ap);
void (*port_stop) (struct ata_port *ap);
void (*host_stop) (struct ata_host_set *host_set);
```

`->port_start()` is called just after the data structures for each port are initialized. Typically this is used to alloc per-port DMA buffers / tables / rings, enable DMA engines, and similar tasks. Some drivers also use this entry point as a chance to allocate driver-private memory for `ap->private_data`.

Many drivers use `ata_port_start()` as this hook or call it from their own `port_start()` hooks. `ata_port_start()` allocates space for a legacy IDE PRD table and returns.

`->port_stop()` is called after `->host_stop()`. Its sole function is to release DMA/memory resources, now that they are no longer actively being used. Many drivers also free driver-private data from port at this time.

`->host_stop()` is called after all `->port_stop()` calls have completed. The hook must finalize hardware shutdown, release DMA and other resources, etc. This hook may be specified as NULL, in which case it is not called.

33.3 Error handling

This chapter describes how errors are handled under libata. Readers are advised to read SCSI EH (Documentation/scsi/scsi_eh.rst) and ATA exceptions doc first.

33.3.1 Origins of commands

In libata, a command is represented with `struct ata_queued_cmd` or qc. qc's are preallocated during port initialization and repetitively used for command executions. Currently only one qc is allocated per port but yet-to-be-merged NCQ branch allocates one for each tag and maps each qc to NCQ tag 1-to-1.

libata commands can originate from two sources - libata itself and SCSI midlayer. libata internal commands are used for initialization and error handling. All normal blk requests and commands for SCSI emulation are passed as SCSI commands through queuecommand callback of SCSI host template.

33.3.2 How commands are issued

Internal commands First, qc is allocated and initialized using `ata_qc_new_init()`. Although `ata_qc_new_init()` doesn't implement any wait or retry mechanism when qc is not available, internal commands are currently issued only during initialization and error recovery, so no other command is active and allocation is guaranteed to succeed.

Once allocated qc's taskfile is initialized for the command to be executed. qc currently has two mechanisms to notify completion. One is via `qc->complete_fn()` callback and the other is completion `qc->waiting`. `qc->complete_fn()` callback is the asynchronous path used by normal SCSI translated commands and `qc->waiting` is the synchronous (issuer sleeps in process context) path used by internal commands.

Once initialization is complete, host_set lock is acquired and the qc is issued.

SCSI commands All libata drivers use `ata_scsi_queuecmd()` as `hostt->queuecommand` callback. scmds can either be simulated or translated. No qc is involved in processing a simulated scmd. The result is computed right away and the scmd is completed.

For a translated scmd, `ata_qc_new_init()` is invoked to allocate a qc and the scmd is translated into the qc. SCSI midlayer's completion notification function pointer is stored into `qc->scsidone`.

`qc->complete_fn()` callback is used for completion notification. ATA commands use `ata_scsi_qc_complete()` while ATAPI commands use `atapi_qc_complete()`. Both functions end up calling `qc->scsidone` to notify upper layer when the qc is finished. After translation is completed, the qc is issued with `ata_qc_issue()`.

Note that SCSI midlayer invokes hostt->queuecommand while holding host_set lock, so all above occur while holding host_set lock.

33.3.3 How commands are processed

Depending on which protocol and which controller are used, commands are processed differently. For the purpose of discussion, a controller which uses taskfile interface and all standard callbacks is assumed.

Currently 6 ATA command protocols are used. They can be sorted into the following four categories according to how they are processed.

ATA NO DATA or DMA ATA_PROT_NODATA and ATA_PROT_DMA fall into this category. These types of commands don't require any software intervention once issued. Device will raise interrupt on completion.

ATA PIO ATA_PROT_PIO is in this category. libata currently implements PIO with polling. ATA_NIEN bit is set to turn off interrupt and pio_task on ata_wq performs polling and IO.

ATAPI NODATA or DMA ATA_PROT_ATAPI_NODATA and ATA_PROT_ATAPI_DMA are in this category. packet_task is used to poll BSY bit after issuing PACKET command. Once BSY is turned off by the device, packet_task transfers CDB and hands off processing to interrupt handler.

ATAPI PIO ATA_PROT_ATAPI is in this category. ATA_NIEN bit is set and, as in ATAPI NODATA or DMA, packet_task submits cdb. However, after submitting cdb, further processing (data transfer) is handed off to pio_task.

33.3.4 How commands are completed

Once issued, all qc's are either completed with `ata_qc_complete()` or time out. For commands which are handled by interrupts, `ata_host_intr()` invokes `ata_qc_complete()`, and, for PIO tasks, pio_task invokes `ata_qc_complete()`. In error cases, packet_task may also complete commands.

`ata_qc_complete()` does the following.

1. DMA memory is unmapped.
2. ATA_QCFLAG_ACTIVE is cleared from qc->flags.
3. `qc->complete_fn()` callback is invoked. If the return value of the callback is not zero. Completion is short circuited and `ata_qc_complete()` returns.

4. `__ata_qc_complete()` is called, which does
    1. `qc->flags` is cleared to zero.
    2. `ap->active_tag` and `qc->tag` are poisoned.
    3. `qc->waiting` is cleared & completed (in that order).
    4. qc is deallocated by clearing appropriate bit in `ap->qactive`.

So, it basically notifies upper layer and deallocates qc. One exception is short-circuit path in #3 which is used by `atapi_qc_complete()`.

For all non-ATAPI commands, whether it fails or not, almost the same code path is taken and very little error handling takes place. A qc is completed with success status if it succeeded, with failed status otherwise.

However, failed ATAPI commands require more handling as REQUEST SENSE is needed to acquire sense data. If an ATAPI command fails, `ata_qc_complete()` is invoked with error status, which in turn invokes `atapi_qc_complete()` via `qc->complete_fn()` callback.

This makes `atapi_qc_complete()` set `scmd->result` to SAM_STAT_CHECK_CONDITION, complete the scmd and return 1. As the sense data is empty but `scmd->result` is CHECK CONDITION, SCSI midlayer will invoke EH for the scmd, and returning 1 makes `ata_qc_complete()` to return without deallocating the qc. This leads us to `ata_scsi_error()` with partially completed qc.

33.3.5 ata_scsi_error()

`ata_scsi_error()` is the current `transportt->eh_strategy_handler()` for libata. As discussed above, this will be entered in two cases - timeout and ATAPI error completion. This function calls low level libata driver's `eng_timeout()` callback, the standard callback for which is `ata_eng_timeout()`. It checks if a qc is active and calls `ata_qc_timeout()` on the qc if so. Actual error handling occurs in `ata_qc_timeout()`.

If EH is invoked for timeout, `ata_qc_timeout()` stops BMDMA and completes the qc. Note that as we're currently in EH, we cannot call scsi_done. As described in SCSI EH doc, a recovered scmd should be either retried with `scsi_queue_insert()` or finished with `scsi_finish_command()`. Here, we override `qc->scsidone` with `scsi_finish_command()` and calls `ata_qc_complete()`.

If EH is invoked due to a failed ATAPI qc, the qc here is completed but not deallocated. The purpose of this half-completion is to use the qc as place holder to make EH code reach this place. This is a bit hackish, but it works.

Once control reaches here, the qc is deallocated by invoking `__ata_qc_complete()` explicitly. Then, internal qc for REQUEST SENSE is issued. Once sense data is acquired, scmd is finished by directly invoking `scsi_finish_command()` on the scmd. Note that as we already have completed and deallocated the qc which was associated with the scmd, we don't need to/cannot call `ata_qc_complete()` again.

33.3.6 Problems with the current EH

- Error representation is too crude. Currently any and all error conditions are represented with ATA STATUS and ERROR registers. Errors which aren't ATA device errors are treated as ATA device errors by setting ATA_ERR bit. Better error descriptor which can properly represent ATA and other errors/exceptions is needed.
- When handling timeouts, no action is taken to make device forget about the timed out command and ready for new commands.
- EH handling via `ata_scsi_error()` is not properly protected from usual command processing. On EH entrance, the device is not in quiescent state. Timed out commands may succeed or fail any time. pio_task and atapi_task may still be running.
- Too weak error recovery. Devices / controllers causing HSM mismatch errors and other errors quite often require reset to return to known state. Also, advanced error handling is necessary to support features like NCQ and hotplug.
- ATA errors are directly handled in the interrupt handler and PIO errors in pio_task. This is problematic for advanced error handling for the following reasons.

  First, advanced error handling often requires context and internal qc execution.

  Second, even a simple failure (say, CRC error) needs information gathering and could trigger complex error handling (say, resetting & reconfiguring). Having multiple code paths to gather information, enter EH and trigger actions makes life painful.

  Third, scattered EH code makes implementing low level drivers difficult. Low level drivers override libata callbacks. If EH is scattered over several places, each affected callbacks should perform its part of error handling. This can be error prone and painful.

33.4 libata Library

struct ata_link * **ata_link_next**(struct ata_link * link, struct ata_port * ap,
enum ata_link_iter_mode mode)

link iteration helper

Parameters

struct ata_link * link the previous link, NULL to start

struct ata_port * ap ATA port containing links to iterate

enum ata_link_iter_mode mode iteration mode, one of ATA_LITER_*

LOCKING: Host lock or EH context.

Return

Pointer to the next link.

struct ata_device * **ata_dev_next**(struct ata_device * dev, struct ata_link * link, enum ata_dev_iter_mode mode)
device iteration helper

Parameters

struct ata_device * dev the previous device, NULL to start

struct ata_link * link ATA link containing devices to iterate

enum ata_dev_iter_mode mode iteration mode, one of ATA_DITER_*

LOCKING: Host lock or EH context.

Return

Pointer to the next device.

int **atapi_cmd_type**(u8 opcode)
Determine ATAPI command type from SCSI opcode

Parameters

u8 opcode SCSI opcode

Determine ATAPI command type from **opcode**.

LOCKING: None.

Return

ATAPI_{READ|WRITE|READ_CD|PASS_THRU|MISC}

unsigned long **ata_pack_xfermask**(unsigned long pio_mask, unsigned long mwdma_mask, unsigned long udma_mask)
Pack pio, mwdma and udma masks into xfer_mask

Parameters

unsigned long pio_mask pio_mask

unsigned long mwdma_mask mwdma_mask

unsigned long udma_mask udma_mask

Pack **pio_mask**, **mwdma_mask** and **udma_mask** into a single unsigned int xfer_mask.

LOCKING: None.

Return

Packed xfer_mask.

u8 **ata_xfer_mask2mode**(unsigned long xfer_mask)
Find matching XFER_* for the given xfer_mask

Parameters

unsigned long xfer_mask xfer_mask of interest

Return matching XFER_* value for **xfer_mask**. Only the highest bit of **xfer_mask** is considered.

LOCKING: None.

Return

Matching XFER_* value, 0xff if no match found.

unsigned long **ata_xfer_mode2mask**(u8 xfer_mode)
Find matching xfer_mask for XFER_*

Parameters

u8 xfer_mode XFER_* of interest

Return matching xfer_mask for **xfer_mode**.

LOCKING: None.

Return

Matching xfer_mask, 0 if no match found.

int **ata_xfer_mode2shift**(unsigned long xfer_mode)
Find matching xfer_shift for XFER_*

Parameters

unsigned long xfer_mode XFER_* of interest

Return matching xfer_shift for **xfer_mode**.

LOCKING: None.

Return

Matching xfer_shift, -1 if no match found.

const char * **ata_mode_string**(unsigned long xfer_mask)
convert xfer_mask to string

Parameters

unsigned long xfer_mask mask of bits supported; only highest bit counts.

Determine string which represents the highest speed (highest bit in **mode_mask**).

LOCKING: None.

Return

Constant C string representing highest speed listed in **mode_mask**, or the constant C string “<n/a>”.

unsigned int **ata_dev_classify**(const struct ata_taskfile * tf)
determine device type based on ATA-spec signature

Parameters

const struct ata_taskfile * tf ATA taskfile register set for device to be identified

Determine from taskfile register contents whether a device is ATA or ATAPI, as per “Signature and persistence” section of ATA/PI spec (volume 1, sect 5.14).

LOCKING: None.

Return

Device type, `ATA_DEV_ATA`, `ATA_DEV_ATAPI`, `ATA_DEV_PMP`, `ATA_DEV_ZAC`, or `ATA_DEV_UNKNOWN` the event of failure.

void **ata_id_string**(const u16 * id, unsigned char * s, unsigned int ofs, unsigned int len)
Convert IDENTIFY DEVICE page into string

Parameters

const u16 * id IDENTIFY DEVICE results we will examine

unsigned char * s string into which data is output

unsigned int ofs offset into identify device page

unsigned int len length of string to return. must be an even number.

The strings in the IDENTIFY DEVICE page are broken up into 16-bit chunks. Run through the string, and output each 8-bit chunk linearly, regardless of platform.

LOCKING: caller.

void **ata_id_c_string**(const u16 * id, unsigned char * s, unsigned int ofs, unsigned int len)
Convert IDENTIFY DEVICE page into C string

Parameters

const u16 * id IDENTIFY DEVICE results we will examine

unsigned char * s string into which data is output

unsigned int ofs offset into identify device page

unsigned int len length of string to return. must be an odd number.

This function is identical to ata_id_string except that it trims trailing spaces and terminates the resulting string with null. **len** must be actual maximum length (even number) + 1.

LOCKING: caller.

unsigned long **ata_id_xfermask**(const u16 * id)
Compute xfermask from the given IDENTIFY data

Parameters

const u16 * id IDENTIFY data to compute xfer mask from

Compute the xfermask for this device. This is not as trivial as it seems if we must consider early devices correctly.

FIXME: pre IDE drive timing (do we care ?).

LOCKING: None.

Return

Computed xfermask

unsigned int **ata_pio_need_iordy**(const struct ata_device * adev)
check if iordy needed

Parameters

const struct ata_device * adev ATA device

Check if the current speed of the device requires IORDY. Used by various controllers for chip configuration.

unsigned int **ata_do_dev_read_id**(struct ata_device * dev, struct ata_taskfile * tf, u16 * id)
default ID read method

Parameters

struct ata_device * dev device

struct ata_taskfile * tf proposed taskfile

u16 * id data buffer

Issue the identify taskfile and hand back the buffer containing identify data. For some RAID controllers and for pre ATA devices this function is wrapped or replaced by the driver

int **ata_cable_40wire**(struct ata_port * ap)
return 40 wire cable type

Parameters

struct ata_port * ap port

Helper method for drivers which want to hardwire 40 wire cable detection.

int **ata_cable_80wire**(struct ata_port * ap)
return 80 wire cable type

Parameters

struct ata_port * ap port

Helper method for drivers which want to hardwire 80 wire cable detection.

int **ata_cable_unknown**(struct ata_port * ap)
return unknown PATA cable.

Parameters

struct ata_port * ap port

Helper method for drivers which have no PATA cable detection.

int **ata_cable_ignore**(struct ata_port * ap)
return ignored PATA cable.

Parameters

struct ata_port * ap port

Helper method for drivers which don't use cable type to limit transfer mode.

int **ata_cable_sata**(struct ata_port * ap)
return SATA cable type

Parameters

struct ata_port * ap port

Helper method for drivers which have SATA cables

struct ata_device * **ata_dev_pair**(struct ata_device * adev)
return other device on cable

Parameters

struct ata_device * adev device

Obtain the other device on the same cable, or if none is present NULL is returned

int **ata_do_set_mode**(struct ata_link * link, struct ata_device ** r_failed_dev)
Program timings and issue SET FEATURES - XFER

Parameters

struct ata_link * link link on which timings will be programmed

struct ata_device ** r_failed_dev out parameter for failed device

Standard implementation of the function used to tune and set ATA device disk transfer mode (PIO3, UDMA6, etc.). If ata_dev_set_mode() fails, pointer to the failing device is returned in **r_failed_dev**.

LOCKING: PCI/etc. bus probe sem.

Return

0 on success, negative errno otherwise

int **ata_wait_after_reset**(struct ata_link * link, unsigned long deadline, int (*check_ready)(struct ata_link *link))
wait for link to become ready after reset

Parameters

struct ata_link * link link to be waited on

unsigned long deadline deadline jiffies for the operation

int (*)(struct ata_link *link) check_ready callback to check link readiness

Wait for **link** to become ready after reset.

LOCKING: EH context.

Return

0 if **link** is ready before **deadline**; otherwise, -errno.

int **ata_std_prereset**(struct ata_link * link, unsigned long deadline)
prepare for reset

Parameters

struct ata_link * link ATA link to be reset

unsigned long deadline deadline jiffies for the operation

link is about to be reset. Initialize it. Failure from prereset makes libata abort whole reset sequence and give up that port, so prereset should be best-effort. It does its best to prepare for reset sequence but if things go wrong, it should just whine, not fail.

LOCKING: Kernel thread context (may sleep)

Return

0 on success, -errno otherwise.

int **sata_std_hardreset**(struct ata_link * link, unsigned int * class, unsigned long deadline)
COMRESET w/o waiting or classification

Parameters

struct ata_link * link link to reset

unsigned int * class resulting class of attached device

unsigned long deadline deadline jiffies for the operation

Standard SATA COMRESET w/o waiting or classification.

LOCKING: Kernel thread context (may sleep)

Return

0 if link offline, -EAGAIN if link online, -errno on errors.

void **ata_std_postreset**(struct ata_link * link, unsigned int * classes)
standard postreset callback

Parameters

struct ata_link * link the target ata_link

unsigned int * classes classes of attached devices

This function is invoked after a successful reset. Note that the device might have been reset more than once using different reset methods before postreset is invoked.

LOCKING: Kernel thread context (may sleep)

unsigned int **ata_dev_set_feature**(struct ata_device * dev, u8 enable, u8 feature)
Issue SET FEATURES - SATA FEATURES

Parameters

struct ata_device * dev Device to which command will be sent

u8 enable Whether to enable or disable the feature

u8 feature The sector count represents the feature to set

Issue SET FEATURES - SATA FEATURES command to device **dev** on port **ap** with sector count

LOCKING: PCI/etc. bus probe sem.

Return

0 on success, AC_ERR_* mask otherwise.

int **ata_std_qc_defer**(struct ata_queued_cmd * qc)
Check whether a qc needs to be deferred

Parameters

struct ata_queued_cmd * qc ATA command in question

Non-NCQ commands cannot run with any other command, NCQ or not. As upper layer only knows the queue depth, we are responsible for maintaining exclusion. This function checks whether a new command **qc** can be issued.

LOCKING: spin_lock_irqsave(host lock)

Return

ATA_DEFER_* if deferring is needed, 0 otherwise.

void **ata_qc_complete**(struct ata_queued_cmd * qc)
Complete an active ATA command

Parameters

struct ata_queued_cmd * qc Command to complete

Indicate to the mid and upper layers that an ATA command has completed, with either an ok or not-ok status.

Refrain from calling this function multiple times when successfully completing multiple NCQ commands. ata_qc_complete_multiple() should be used instead, which will properly update IRQ expect state.

LOCKING: spin_lock_irqsave(host lock)

u64 **ata_qc_get_active**(struct ata_port * ap)
get bitmask of active qcs

Parameters

struct ata_port * ap port in question

LOCKING: spin_lock_irqsave(host lock)

Return

Bitmask of active qcs

bool **ata_link_online**(struct ata_link * link)
test whether the given link is online

Parameters

struct ata_link * link ATA link to test

Test whether **link** is online. This is identical to `ata_phys_link_online()` when there's no slave link. When there's a slave link, this function should only be called on the master link and will return true if any of M/S links is online.

LOCKING: None.

Return

True if the port online status is available and online.

bool **ata_link_offline**(struct ata_link * link)
test whether the given link is offline

Parameters

struct ata_link * link ATA link to test

Test whether **link** is offline. This is identical to `ata_phys_link_offline()` when there's no slave link. When there's a slave link, this function should only be called on the master link and will return true if both M/S links are offline.

LOCKING: None.

Return

True if the port offline status is available and offline.

int **ata_host_suspend**(struct ata_host * host, pm_message_t mesg)
suspend host

Parameters

struct ata_host * host host to suspend

pm_message_t mesg PM message

Suspend **host**. Actual operation is performed by port suspend.

void **ata_host_resume**(struct ata_host * host)
resume host

Parameters

struct ata_host * host host to resume

Resume **host**. Actual operation is performed by port resume.

struct ata_host * **ata_host_alloc**(struct device * dev, int max_ports)
allocate and init basic ATA host resources

Parameters

struct device * dev generic device this host is associated with

int max_ports maximum number of ATA ports associated with this host

Allocate and initialize basic ATA host resources. LLD calls this function to allocate a host, initializes it fully and attaches it using `ata_host_register()`.

max_ports ports are allocated and host->n_ports is initialized to **max_ports**. The caller is allowed to decrease host->n_ports before calling `ata_host_register()`. The unused ports will be automatically freed on registration.

Return

Allocate ATA host on success, NULL on failure.

LOCKING: Inherited from calling layer (may sleep).

struct ata_host * **ata_host_alloc_pinfo**(struct device * dev, const struct ata_port_info *const * ppi, int n_ports)
alloc host and init with port_info array

Parameters

struct device * dev generic device this host is associated with

const struct ata_port_info *const * ppi array of ATA port_info to initialize host with

int n_ports number of ATA ports attached to this host

Allocate ATA host and initialize with info from **ppi**. If NULL terminated, **ppi** may contain fewer entries than **n_ports**. The last entry will be used for the remaining ports.

Return

Allocate ATA host on success, NULL on failure.

LOCKING: Inherited from calling layer (may sleep).

int **ata_host_start**(struct ata_host * host)
start and freeze ports of an ATA host

Parameters

struct ata_host * host ATA host to start ports for

Start and then freeze ports of **host**. Started status is recorded in host->flags, so this function can be called multiple times. Ports are guaranteed to get started only once. If host->ops isn't initialized yet, its set to the first non-dummy port ops.

LOCKING: Inherited from calling layer (may sleep).

Return

0 if all ports are started successfully, -errno otherwise.

void **ata_host_init**(struct ata_host * host, struct device * dev, struct ata_port_operations * ops)
Initialize a host struct for sas (ipr, libsas)

Parameters

struct ata_host * host host to initialize

struct device * dev device host is attached to

struct ata_port_operations * ops port_ops

int **ata_host_register**(struct ata_host * host, struct scsi_host_template * sht)
register initialized ATA host

Parameters

struct ata_host * host ATA host to register

struct scsi_host_template * sht template for SCSI host

Register initialized ATA host. **host** is allocated using `ata_host_alloc()` and fully initialized by LLD. This function starts ports, registers **host** with ATA and SCSI layers and probe registered devices.

LOCKING: Inherited from calling layer (may sleep).

Return

0 on success, -errno otherwise.

int **ata_host_activate**(struct ata_host * host, int irq, irq_handler_t irq_handler, unsigned long irq_flags, struct scsi_host_template * sht)
start host, request IRQ and register it

Parameters

struct ata_host * host target ATA host

int irq IRQ to request

irq_handler_t irq_handler irq_handler used when requesting IRQ

unsigned long irq_flags irq_flags used when requesting IRQ

struct scsi_host_template * sht scsi_host_template to use when registering the host

After allocating an ATA host and initializing it, most libata LLDs perform three steps to activate the host - start host, request IRQ and register it. This helper takes necessary arguments and performs the three steps in one go.

An invalid IRQ skips the IRQ registration and expects the host to have set polling mode on the port. In this case, **irq_handler** should be NULL.

LOCKING: Inherited from calling layer (may sleep).

Return

0 on success, -errno otherwise.

void **ata_host_detach**(struct ata_host * host)
Detach all ports of an ATA host

Parameters

struct ata_host * host Host to detach

Detach all ports of **host**.

LOCKING: Kernel thread context (may sleep).

void **ata_pci_remove_one**(struct pci_dev * pdev)
PCI layer callback for device removal

Parameters

struct pci_dev * pdev PCI device that was removed

PCI layer indicates to libata via this hook that hot-unplug or module unload event has occurred. Detach all ports. Resource release is handled via devres.

LOCKING: Inherited from PCI layer (may sleep).

int **ata_platform_remove_one**(struct platform_device * pdev)
Platform layer callback for device removal

Parameters

struct platform_device * pdev Platform device that was removed

Platform layer indicates to libata via this hook that hot-unplug or module unload event has occurred. Detach all ports. Resource release is handled via devres.

LOCKING: Inherited from platform layer (may sleep).

void **ata_msleep**(struct ata_port * ap, unsigned int msecs)
ATA EH owner aware msleep

Parameters

struct ata_port * ap ATA port to attribute the sleep to

unsigned int msecs duration to sleep in milliseconds

Sleeps **msecs**. If the current task is owner of **ap**'s EH, the ownership is released before going to sleep and reacquired after the sleep is complete. IOW, other ports sharing the **ap->host** will be allowed to own the EH while this task is sleeping.

LOCKING: Might sleep.

u32 **ata_wait_register**(struct ata_port * ap, void __iomem * reg, u32 mask, u32 val, unsigned long interval, unsigned long timeout)
wait until register value changes

Parameters

struct ata_port * ap ATA port to wait register for, can be NULL

void __iomem * reg IO-mapped register

u32 mask Mask to apply to read register value

u32 val Wait condition

unsigned long interval polling interval in milliseconds

unsigned long timeout timeout in milliseconds

Waiting for some bits of register to change is a common operation for ATA controllers. This function reads 32bit LE IO-mapped register **reg** and tests for the following condition.

(***reg** & mask) != val

If the condition is met, it returns; otherwise, the process is repeated after **interval_msec** until timeout.

LOCKING: Kernel thread context (may sleep)

Return

The final register value.

33.5 libata Core Internals

struct ata_link * **ata_dev_phys_link**(struct ata_device * dev)
find physical link for a device

Parameters

struct ata_device * dev ATA device to look up physical link for

Look up physical link which **dev** is attached to. Note that this is different from **dev->link** only when **dev** is on slave link. For all other cases, it's the same as **dev->link**.

LOCKING: Don't care.

Return

Pointer to the found physical link.

void **ata_force_cbl**(struct ata_port * ap)
force cable type according to libata.force

Parameters

struct ata_port * ap ATA port of interest

Force cable type according to libata.force and whine about it. The last entry which has matching port number is used, so it can be specified as part of device force parameters. For example, both "a:40c,1.00:udma4" and "1.00:40c,udma4" have the same effect.

LOCKING: EH context.

void **ata_force_link_limits**(struct ata_link * link)
force link limits according to libata.force

Parameters

struct ata_link * link ATA link of interest

Force link flags and SATA spd limit according to libata.force and whine about it. When only the port part is specified (e.g. 1:), the limit applies to all links connected to both the host link and all fan-out ports connected via PMP. If the device part is specified as 0 (e.g. 1.00:), it specifies the first fan-out link not the host link. Device number 15 always points to the host link whether PMP is attached or not. If the controller has slave link, device number 16 points to it.

LOCKING: EH context.

void **ata_force_xfermask**(struct ata_device * dev)
force xfermask according to libata.force

Parameters

struct ata_device * dev ATA device of interest

Force xfer_mask according to libata.force and whine about it. For consistency with link selection, device number 15 selects the first device connected to the host link.

LOCKING: EH context.

void **ata_force_horkage**(struct ata_device * dev)
force horkage according to libata.force

Parameters

struct ata_device * dev ATA device of interest

Force horkage according to libata.force and whine about it. For consistency with link selection, device number 15 selects the first device connected to the host link.

LOCKING: EH context.

int **ata_rwcmd_protocol**(struct ata_taskfile * tf, struct ata_device * dev)
set taskfile r/w commands and protocol

Parameters

struct ata_taskfile * tf command to examine and configure

struct ata_device * dev device tf belongs to

Examine the device configuration and tf->flags to calculate the proper read/write commands and protocol to use.

LOCKING: caller.

u64 **ata_tf_read_block**(const struct ata_taskfile * tf, struct ata_device * dev)
Read block address from ATA taskfile

Parameters

const struct ata_taskfile * tf ATA taskfile of interest

struct ata_device * dev ATA device **tf** belongs to

LOCKING: None.

Read block address from **tf**. This function can handle all three address formats - LBA, LBA48 and CHS. tf->protocol and flags select the address format to use.

Return

Block address read from **tf**.

int **ata_build_rw_tf**(struct ata_taskfile * tf, struct ata_device * dev, u64 block, u32 n_block, unsigned int tf_flags, unsigned int tag, int class)
Build ATA taskfile for given read/write request

Parameters

struct ata_taskfile * tf Target ATA taskfile

struct ata_device * dev ATA device **tf** belongs to

u64 block Block address

u32 n_block Number of blocks

unsigned int tf_flags RW/FUA etc…

unsigned int tag tag

int class IO priority class

LOCKING: None.

Build ATA taskfile **tf** for read/write request described by **block**, **n_block**, **tf_flags** and **tag** on **dev**.

Return

0 on success, -ERANGE if the request is too large for **dev**, -EINVAL if the request is invalid.

void **ata_unpack_xfermask**(unsigned long xfer_mask, unsigned long * pio_mask, unsigned long * mwdma_mask, unsigned long * udma_mask)

Unpack xfer_mask into pio, mwdma and udma masks

Parameters

unsigned long xfer_mask xfer_mask to unpack

unsigned long * pio_mask resulting pio_mask

unsigned long * mwdma_mask resulting mwdma_mask

unsigned long * udma_mask resulting udma_mask

Unpack **xfer_mask** into **pio_mask**, **mwdma_mask** and **udma_mask**. Any NULL destination masks will be ignored.

int **ata_read_native_max_address**(struct ata_device * dev, u64 * max_sectors)

Read native max address

Parameters

struct ata_device * dev target device

u64 * max_sectors out parameter for the result native max address

Perform an LBA48 or LBA28 native size query upon the device in question.

Return

0 on success, -EACCES if command is aborted by the drive. -EIO on other errors.

int **ata_set_max_sectors**(struct ata_device * dev, u64 new_sectors)

Set max sectors

Parameters

struct ata_device * dev target device

u64 new_sectors new max sectors value to set for the device

Set max sectors of **dev** to **new_sectors**.

Return

0 on success, -EACCES if command is aborted or denied (due to previous non-volatile SET_MAX) by the drive. -EIO on other errors.

int **ata_hpa_resize**(struct ata_device * dev)
Resize a device with an HPA set

Parameters

struct ata_device * dev Device to resize

Read the size of an LBA28 or LBA48 disk with HPA features and resize it if required to the full size of the media. The caller must check the drive has the HPA feature set enabled.

Return

0 on success, -errno on failure.

void **ata_dump_id**(const u16 * id)
IDENTIFY DEVICE info debugging output

Parameters

const u16 * id IDENTIFY DEVICE page to dump

Dump selected 16-bit words from the given IDENTIFY DEVICE page.

LOCKING: caller.

unsigned **ata_exec_internal_sg**(struct ata_device * dev, struct ata_taskfile * tf, const u8 * cdb, int dma_dir, struct scatterlist * sgl, unsigned int n_elem, unsigned long timeout)
execute libata internal command

Parameters

struct ata_device * dev Device to which the command is sent

struct ata_taskfile * tf Taskfile registers for the command and the result

const u8 * cdb CDB for packet command

int dma_dir Data transfer direction of the command

struct scatterlist * sgl sg list for the data buffer of the command

unsigned int n_elem Number of sg entries

unsigned long timeout Timeout in msecs (0 for default)

Executes libata internal command with timeout. **tf** contains command on entry and result on return. Timeout and error conditions are reported via return value. No recovery action is taken after a command times out. It's caller's duty to clean up after timeout.

LOCKING: None. Should be called with kernel context, might sleep.

Return

Zero on success, AC_ERR_* mask on failure

unsigned **ata_exec_internal**(struct ata_device * dev, struct ata_taskfile * tf, const u8 * cdb, int dma_dir, void * buf, unsigned int buflen, unsigned long timeout)
execute libata internal command

Parameters

struct ata_device * dev Device to which the command is sent

struct ata_taskfile * tf Taskfile registers for the command and the result

const u8 * cdb CDB for packet command

int dma_dir Data transfer direction of the command

void * buf Data buffer of the command

unsigned int buflen Length of data buffer

unsigned long timeout Timeout in msecs (0 for default)

Wrapper around `ata_exec_internal_sg()` which takes simple buffer instead of sg list.

LOCKING: None. Should be called with kernel context, might sleep.

Return

Zero on success, AC_ERR_* mask on failure

u32 **ata_pio_mask_no_iordy**(const struct ata_device * adev)
Return the non IORDY mask

Parameters

const struct ata_device * adev ATA device

Compute the highest mode possible if we are not using iordy. Return -1 if no iordy mode is available.

int **ata_dev_read_id**(struct ata_device * dev, unsigned int * p_class, unsigned int flags, u16 * id)
Read ID data from the specified device

Parameters

struct ata_device * dev target device

unsigned int * p_class pointer to class of the target device (may be changed)

unsigned int flags ATA_READID_* flags

u16 * id buffer to read IDENTIFY data into

Read ID data from the specified device. ATA_CMD_ID_ATA is performed on ATA devices and ATA_CMD_ID_ATAPI on ATAPI devices. This function also issues ATA_CMD_INIT_DEV_PARAMS for pre-ATA4 drives.

FIXME: ATA_CMD_ID_ATA is optional for early drives and right now we abort if we hit that case.

LOCKING: Kernel thread context (may sleep)

Return

0 on success, -errno otherwise.

unsigned int **ata_read_log_page**(struct ata_device * dev, u8 log, u8 page, void * buf, unsigned int sectors)
read a specific log page

Parameters

struct ata_device * dev target device

u8 log log to read

u8 page page to read

void * buf buffer to store read page

unsigned int sectors number of sectors to read

Read log page using READ_LOG_EXT command.

LOCKING: Kernel thread context (may sleep).

Return

0 on success, AC_ERR_* mask otherwise.

int **ata_dev_configure**(struct ata_device * dev)
Configure the specified ATA/ATAPI device

Parameters

struct ata_device * dev Target device to configure

Configure **dev** according to **dev->id**. Generic and low-level driver specific fixups are also applied.

LOCKING: Kernel thread context (may sleep)

Return

0 on success, -errno otherwise

int **ata_bus_probe**(struct ata_port * ap)
Reset and probe ATA bus

Parameters

struct ata_port * ap Bus to probe

Master ATA bus probing function. Initiates a hardware-dependent bus reset, then attempts to identify any devices found on the bus.

LOCKING: PCI/etc. bus probe sem.

Return

Zero on success, negative errno otherwise.

void **sata_print_link_status**(struct ata_link * link)
Print SATA link status

Parameters

struct ata_link * link SATA link to printk link status about

This function prints link speed and status of a SATA link.

LOCKING: None.

int **sata_down_spd_limit**(struct ata_link * link, u32 spd_limit)
adjust SATA spd limit downward

Parameters

struct ata_link * link Link to adjust SATA spd limit for

u32 spd_limit Additional limit

Adjust SATA spd limit of **link** downward. Note that this function only adjusts the limit. The change must be applied using sata_set_spd().

If **spd_limit** is non-zero, the speed is limited to equal to or lower than **spd_limit** if such speed is supported. If **spd_limit** is slower than any supported speed, only the lowest supported speed is allowed.

LOCKING: Inherited from caller.

Return

0 on success, negative errno on failure

u8 **ata_timing_cycle2mode**(unsigned int xfer_shift, int cycle)
find xfer mode for the specified cycle duration

Parameters

unsigned int xfer_shift ATA_SHIFT_* value for transfer type to examine.

int cycle cycle duration in ns

Return matching xfer mode for **cycle**. The returned mode is of the transfer type specified by **xfer_shift**. If **cycle** is too slow for **xfer_shift**, 0xff is returned. If **cycle** is faster than the fastest known mode, the fasted mode is returned.

LOCKING: None.

Return

Matching xfer_mode, 0xff if no match found.

int **ata_down_xfermask_limit**(struct ata_device * dev, unsigned int sel)
adjust dev xfer masks downward

Parameters

struct ata_device * dev Device to adjust xfer masks

unsigned int sel ATA_DNXFER_* selector

Adjust xfer masks of **dev** downward. Note that this function does not apply the change. Invoking `ata_set_mode()` afterwards will apply the limit.

LOCKING: Inherited from caller.

Return

0 on success, negative errno on failure

int **ata_wait_ready**(struct ata_link * link, unsigned long deadline, int (*check_ready)(struct ata_link *link))
wait for link to become ready

Parameters

struct ata_link * link link to be waited on

unsigned long deadline deadline jiffies for the operation

int (*)(struct ata_link *link) check_ready callback to check link readiness

Wait for **link** to become ready. **check_ready** should return positive number if **link** is ready, 0 if it isn't, -ENODEV if link doesn't seem to be occupied, other errno for other error conditions.

Transient -ENODEV conditions are allowed for ATA_TMOUT_FF_WAIT.

LOCKING: EH context.

Return

0 if **link** is ready before **deadline**; otherwise, -errno.

int **ata_dev_same_device**(struct ata_device * dev, unsigned int new_class, const u16 * new_id)
Determine whether new ID matches configured device

Parameters

struct ata_device * dev device to compare against

unsigned int new_class class of the new device

const u16 * new_id IDENTIFY page of the new device

Compare **new_class** and **new_id** against **dev** and determine whether **dev** is the device indicated by **new_class** and **new_id**.

LOCKING: None.

Return

1 if **dev** matches **new_class** and **new_id**, 0 otherwise.

int **ata_dev_reread_id**(struct ata_device * dev, unsigned int readid_flags)
Re-read IDENTIFY data

Parameters

struct ata_device * dev target ATA device

unsigned int readid_flags read ID flags

Re-read IDENTIFY page and make sure **dev** is still attached to the port.

LOCKING: Kernel thread context (may sleep)

Return

0 on success, negative errno otherwise

int **ata_dev_revalidate**(struct ata_device * dev, unsigned int new_class, unsigned int readid_flags)
Revalidate ATA device

Parameters

struct ata_device * dev device to revalidate

unsigned int new_class new class code

unsigned int readid_flags read ID flags

Re-read IDENTIFY page, make sure **dev** is still attached to the port and reconfigure it according to the new IDENTIFY page.

LOCKING: Kernel thread context (may sleep)

Return

0 on success, negative errno otherwise

int **ata_is_40wire**(struct ata_device * dev)
check drive side detection

Parameters

struct ata_device * dev device

Perform drive side detection decoding, allowing for device vendors who can't follow the documentation.

int **cable_is_40wire**(struct ata_port * ap)
40/80/SATA decider

Parameters

struct ata_port * ap port to consider

This function encapsulates the policy for speed management in one place. At the moment we don't cache the result but there is a good case for setting ap->cbl to the result when we are called with unknown cables (and figuring out if it impacts hotplug at all).

Return 1 if the cable appears to be 40 wire.

void **ata_dev_xfermask**(struct ata_device * dev)
Compute supported xfermask of the given device

Parameters

struct ata_device * dev Device to compute xfermask for

Compute supported xfermask of **dev** and store it in dev->*_mask. This function is responsible for applying all known limits including host controller limits, device blacklist, etc…

LOCKING: None.

unsigned int **ata_dev_set_xfermode**(struct ata_device * dev)
Issue SET FEATURES - XFER MODE command

Parameters

struct ata_device * dev Device to which command will be sent

Issue SET FEATURES - XFER MODE command to device **dev** on port **ap**.

LOCKING: PCI/etc. bus probe sem.

Return

0 on success, AC_ERR_* mask otherwise.

unsigned int **ata_dev_init_params**(struct ata_device * dev, u16 heads, u16 sectors)
Issue INIT DEV PARAMS command

Parameters

struct ata_device * dev Device to which command will be sent

u16 heads Number of heads (taskfile parameter)

u16 sectors Number of sectors (taskfile parameter)

LOCKING: Kernel thread context (may sleep)

Return

0 on success, AC_ERR_* mask otherwise.

int **atapi_check_dma**(struct ata_queued_cmd * qc)
Check whether ATAPI DMA can be supported

Parameters

struct ata_queued_cmd * qc Metadata associated with taskfile to check

Allow low-level driver to filter ATA PACKET commands, returning a status indicating whether or not it is OK to use DMA for the supplied PACKET command.

LOCKING: spin_lock_irqsave(host lock)

Return

0 when ATAPI DMA can be used nonzero otherwise

void **ata_sg_init**(struct ata_queued_cmd * qc, struct scatterlist * sg, unsigned int n_elem)
Associate command with scatter-gather table.

Parameters

struct ata_queued_cmd * qc Command to be associated

struct scatterlist * sg Scatter-gather table.

unsigned int n_elem Number of elements in s/g table.

Initialize the data-related elements of queued_cmd **qc** to point to a scatter-gather table **sg**, containing **n_elem** elements.

LOCKING: spin_lock_irqsave(host lock)

void **ata_sg_clean**(struct ata_queued_cmd * qc)
Unmap DMA memory associated with command

Parameters

struct ata_queued_cmd * qc Command containing DMA memory to be released

Unmap all mapped DMA memory associated with this command.

LOCKING: spin_lock_irqsave(host lock)

int **ata_sg_setup**(struct ata_queued_cmd * qc)
DMA-map the scatter-gather table associated with a command.

Parameters

struct ata_queued_cmd * qc Command with scatter-gather table to be mapped.

DMA-map the scatter-gather table associated with queued_cmd **qc**.

LOCKING: spin_lock_irqsave(host lock)

Return

Zero on success, negative on error.

void **swap_buf_le16**(u16 * buf, unsigned int buf_words)
swap halves of 16-bit words in place

Parameters

u16 * buf Buffer to swap

unsigned int buf_words Number of 16-bit words in buffer.

Swap halves of 16-bit words if needed to convert from little-endian byte order to native cpu byte order, or vice-versa.

LOCKING: Inherited from caller.

struct ata_queued_cmd * **ata_qc_new_init**(struct ata_device * dev, int tag)
Request an available ATA command, and initialize it

Parameters

struct ata_device * dev Device from whom we request an available command structure

int tag tag

LOCKING: None.

void **ata_qc_free**(struct ata_queued_cmd * qc)
free unused ata_queued_cmd

Parameters

struct ata_queued_cmd * qc Command to complete

Designed to free unused ata_queued_cmd object in case something prevents using it.

LOCKING: spin_lock_irqsave(host lock)

void **ata_qc_issue**(struct ata_queued_cmd * qc)
issue taskfile to device

Parameters

struct ata_queued_cmd * qc command to issue to device

Prepare an ATA command to submission to device. This includes mapping the data into a DMA-able area, filling in the S/G table, and finally writing the taskfile to hardware, starting the command.

LOCKING: spin_lock_irqsave(host lock)

bool **ata_phys_link_online**(struct ata_link * link)
test whether the given link is online

Parameters

struct ata_link * link ATA link to test

Test whether **link** is online. Note that this function returns 0 if online status of **link** cannot be obtained, so ata_link_online(link) != !ata_link_offline(link).

LOCKING: None.

Return

True if the port online status is available and online.

bool **ata_phys_link_offline**(struct ata_link * link)
test whether the given link is offline

Parameters

struct ata_link * link ATA link to test

Test whether **link** is offline. Note that this function returns 0 if offline status of **link** cannot be obtained, so ata_link_online(link) != !ata_link_offline(link).

LOCKING: None.

Return

True if the port offline status is available and offline.

void **ata_dev_init**(struct ata_device * dev)
Initialize an ata_device structure

Parameters

struct ata_device * dev Device structure to initialize

Initialize **dev** in preparation for probing.

LOCKING: Inherited from caller.

void **ata_link_init**(struct ata_port * ap, struct ata_link * link, int pmp)
Initialize an ata_link structure

Parameters

struct ata_port * ap ATA port link is attached to

struct ata_link * link Link structure to initialize

int pmp Port multiplier port number

Initialize **link**.

LOCKING: Kernel thread context (may sleep)

int **sata_link_init_spd**(struct ata_link * link)
Initialize link->sata_spd_limit

Parameters

struct ata_link * link Link to configure sata_spd_limit for

Initialize `link->[hw_]sata_spd_limit` to the currently configured value.

LOCKING: Kernel thread context (may sleep).

Return

0 on success, -errno on failure.

struct ata_port * **ata_port_alloc**(struct ata_host * host)
allocate and initialize basic ATA port resources

Parameters

struct ata_host * host ATA host this allocated port belongs to

Allocate and initialize basic ATA port resources.

Return

Allocate ATA port on success, NULL on failure.

LOCKING: Inherited from calling layer (may sleep).

void **ata_finalize_port_ops**(struct ata_port_operations * ops)
finalize ata_port_operations

Parameters

struct ata_port_operations * ops ata_port_operations to finalize

An ata_port_operations can inherit from another ops and that ops can again inherit from another. This can go on as many times as necessary as long as there is no loop in the inheritance chain.

Ops tables are finalized when the host is started. NULL or unspecified entries are inherited from the closet ancestor which has the method and the entry is populated with it. After finalization, the ops table directly points to all the methods and ->inherits is no longer necessary and cleared.

Using ATA_OP_NULL, inheriting ops can force a method to NULL.

LOCKING: None.

void **ata_port_detach**(struct ata_port * ap)
Detach ATA port in preparation of device removal

Parameters

struct ata_port * ap ATA port to be detached

Detach all ATA devices and the associated SCSI devices of **ap**; then, remove the associated SCSI host. **ap** is guaranteed to be quiescent on return from this function.

LOCKING: Kernel thread context (may sleep).

void **__ata_ehi_push_desc**(struct ata_eh_info * ehi, const char * fmt, ...)
push error description without adding separator

Parameters

struct ata_eh_info * ehi target EHI

const char * fmt printf format string

Format string according to **fmt** and append it to **ehi->desc**.

LOCKING: spin_lock_irqsave(host lock)

... variable arguments

void **ata_ehi_push_desc**(struct ata_eh_info * ehi, const char * fmt, ...)
push error description with separator

Parameters

struct ata_eh_info * ehi target EHI

const char * fmt printf format string

Format string according to **fmt** and append it to **ehi->desc**. If **ehi->desc** is not empty, ", " is added in-between.

LOCKING: spin_lock_irqsave(host lock)

... variable arguments

void **ata_ehi_clear_desc**(struct ata_eh_info * ehi)
clean error description

Parameters

struct ata_eh_info * ehi target EHI

Clear **ehi->desc**.

LOCKING: spin_lock_irqsave(host lock)

void **ata_port_desc**(struct ata_port * ap, const char * fmt, ...)
append port description

Parameters

struct ata_port * ap target ATA port

const char * fmt printf format string

Format string according to **fmt** and append it to port description. If port description is not empty, "" is added in-between. This function is to be used while initializing ata_host. The description is printed on host registration.

LOCKING: None.

... variable arguments

void **ata_port_pbar_desc**(struct ata_port * ap, int bar, ssize_t offset, const char * name)
append PCI BAR description

Parameters

struct ata_port * ap target ATA port

int bar target PCI BAR

ssize_t offset offset into PCI BAR

const char * name name of the area

If **offset** is negative, this function formats a string which contains the name, address, size and type of the BAR and appends it to the port description. If **offset** is zero or positive, only name and offsetted address is appended.

LOCKING: None.

unsigned long **ata_internal_cmd_timeout**(struct ata_device * dev, u8 cmd)
determine timeout for an internal command

Parameters

struct ata_device * dev target device

u8 cmd internal command to be issued

Determine timeout for internal command **cmd** for **dev**.

LOCKING: EH context.

Return

Determined timeout.

void **ata_internal_cmd_timed_out**(struct ata_device * dev, u8 cmd)
notification for internal command timeout

Parameters

struct ata_device * dev target device

u8 cmd internal command which timed out

Notify EH that internal command **cmd** for **dev** timed out. This function should be called only for commands whose timeouts are determined using `ata_internal_cmd_timeout()`.

LOCKING: EH context.

void **ata_eh_acquire**(struct ata_port * ap)
acquire EH ownership

Parameters

struct ata_port * ap ATA port to acquire EH ownership for

Acquire EH ownership for **ap**. This is the basic exclusion mechanism for ports sharing a host. Only one port hanging off the same host can claim the ownership of EH.

LOCKING: EH context.

void **ata_eh_release**(struct ata_port * ap)
release EH ownership

Parameters

struct ata_port * ap ATA port to release EH ownership for

Release EH ownership for **ap** if the caller. The caller must have acquired EH ownership using `ata_eh_acquire()` previously.

LOCKING: EH context.

void **ata_scsi_error**(struct Scsi_Host * host)
SCSI layer error handler callback

Parameters

struct Scsi_Host * host SCSI host on which error occurred

Handles SCSI-layer-thrown error events.

LOCKING: Inherited from SCSI layer (none, can sleep)

Return

Zero.

void **ata_scsi_cmd_error_handler**(struct Scsi_Host * host, struct ata_port * ap, struct list_head * eh_work_q)
error callback for a list of commands

Parameters

struct Scsi_Host * host scsi host containing the port

struct ata_port * ap ATA port within the host

struct list_head * eh_work_q list of commands to process

Description

process the given list of commands and return those finished to the ap->eh_done_q. This function is the first part of the libata error handler which processes a given list of failed commands.

void **ata_scsi_port_error_handler**(struct Scsi_Host * host, struct ata_port * ap)
recover the port after the commands

Parameters

struct Scsi_Host * host SCSI host containing the port

struct ata_port * ap the ATA port

Description

Handle the recovery of the port **ap** after all the commands have been recovered.

void **ata_port_wait_eh**(struct ata_port * ap)
Wait for the currently pending EH to complete

Parameters

struct ata_port * ap Port to wait EH for

Wait until the currently pending EH is complete.

LOCKING: Kernel thread context (may sleep).

void **ata_eh_set_pending**(struct ata_port * ap, int fastdrain)
set ATA_PFLAG_EH_PENDING and activate fast drain

Parameters

struct ata_port * ap target ATA port

int fastdrain activate fast drain

Set ATA_PFLAG_EH_PENDING and activate fast drain if **fastdrain** is non-zero and EH wasn't pending before. Fast drain ensures that EH kicks in in timely manner.

LOCKING: spin_lock_irqsave(host lock)

void **ata_qc_schedule_eh**(struct ata_queued_cmd * qc)
schedule qc for error handling

Parameters

struct ata_queued_cmd * qc command to schedule error handling for

Schedule error handling for **qc**. EH will kick in as soon as other commands are drained.

LOCKING: spin_lock_irqsave(host lock)

void **ata_std_sched_eh**(struct ata_port * ap)
non-libsas ata_ports issue eh with this common routine

Parameters

struct ata_port * ap ATA port to schedule EH for

LOCKING: inherited from ata_port_schedule_eh spin_lock_irqsave(host lock)

void **ata_std_end_eh**(struct ata_port * ap)
non-libsas ata_ports complete eh with this common routine

Parameters

struct ata_port * ap ATA port to end EH for

Description

In the libata object model there is a 1:1 mapping of ata_port to shost, so host fields can be directly manipulated under ap->lock, in the libsas case we need to hold a lock at the ha->level to coordinate these events.

LOCKING: spin_lock_irqsave(host lock)

void **ata_port_schedule_eh**(struct ata_port * ap)
schedule error handling without a qc

Parameters

struct ata_port * ap ATA port to schedule EH for

Schedule error handling for **ap**. EH will kick in as soon as all commands are drained.

LOCKING: spin_lock_irqsave(host lock)

int **ata_link_abort**(struct ata_link * link)
abort all qc's on the link

Parameters

struct ata_link * link ATA link to abort qc's for

Abort all active qc's active on **link** and schedule EH.

LOCKING: spin_lock_irqsave(host lock)

Return

Number of aborted qc's.

int **ata_port_abort**(struct ata_port * ap)
abort all qc's on the port

Parameters

struct ata_port * ap ATA port to abort qc's for

Abort all active qc's of **ap** and schedule EH.

LOCKING: spin_lock_irqsave(host_set lock)

Return

Number of aborted qc's.

void **__ata_port_freeze**(struct ata_port * ap)
freeze port

Parameters

struct ata_port * ap ATA port to freeze

This function is called when HSM violation or some other condition disrupts normal operation of the port. Frozen port is not allowed to perform any operation until the port is thawed, which usually follows a successful reset.

ap->ops->freeze() callback can be used for freezing the port hardware-wise (e.g. mask interrupt and stop DMA engine). If a port cannot be frozen hardware-wise, the interrupt handler must ack and clear interrupts unconditionally while the port is frozen.

LOCKING: spin_lock_irqsave(host lock)

int **ata_port_freeze**(struct ata_port * ap)
abort & freeze port

Parameters

struct ata_port * ap ATA port to freeze

Abort and freeze **ap**. The freeze operation must be called first, because some hardware requires special operations before the taskfile registers are accessible.

LOCKING: spin_lock_irqsave(host lock)

Return

Number of aborted commands.

void **ata_eh_freeze_port**(struct ata_port * ap)
EH helper to freeze port

Parameters

struct ata_port * ap ATA port to freeze

Freeze **ap**.

LOCKING: None.

void **ata_eh_thaw_port**(struct ata_port * ap)
EH helper to thaw port

Parameters

struct ata_port * ap ATA port to thaw

Thaw frozen port **ap**.

LOCKING: None.

void **ata_eh_qc_complete**(struct ata_queued_cmd * qc)
Complete an active ATA command from EH

Parameters

struct ata_queued_cmd * qc Command to complete

Indicate to the mid and upper layers that an ATA command has completed. To be used from EH.

void **ata_eh_qc_retry**(struct ata_queued_cmd * qc)
Tell midlayer to retry an ATA command after EH

Parameters

struct ata_queued_cmd * qc Command to retry

Indicate to the mid and upper layers that an ATA command should be retried. To be used from EH.

SCSI midlayer limits the number of retries to scmd->allowed. scmd->allowed is incremented for commands which get retried due to unrelated failures (qc->err_mask is zero).

void **ata_dev_disable**(struct ata_device * dev)
disable ATA device

Parameters

struct ata_device * dev ATA device to disable

Disable **dev**.

Locking: EH context.

void **ata_eh_detach_dev**(struct ata_device * dev)
detach ATA device

Parameters

struct ata_device * dev ATA device to detach

Detach **dev**.

LOCKING: None.

void **ata_eh_about_to_do**(struct ata_link * link, struct ata_device * dev, unsigned int action)
about to perform eh_action

Parameters

struct ata_link * link target ATA link

struct ata_device * dev target ATA dev for per-dev action (can be NULL)

unsigned int action action about to be performed

Called just before performing EH actions to clear related bits in **link->eh_info** such that eh actions are not unnecessarily repeated.

LOCKING: None.

void **ata_eh_done**(struct ata_link * link, struct ata_device * dev, unsigned int action)
EH action complete

Parameters

struct ata_link * link ATA link for which EH actions are complete

struct ata_device * dev target ATA dev for per-dev action (can be NULL)

unsigned int action action just completed

Called right after performing EH actions to clear related bits in **link->eh_context**.

LOCKING: None.

const char * **ata_err_string**(unsigned int err_mask)
convert err_mask to descriptive string

Parameters

unsigned int err_mask error mask to convert to string

Convert **err_mask** to descriptive string. Errors are prioritized according to severity and only the most severe error is reported.

LOCKING: None.

Return

Descriptive string for **err_mask**

unsigned int **atapi_eh_tur**(struct ata_device * dev, u8 * r_sense_key)
perform ATAPI TEST_UNIT_READY

Parameters

struct ata_device * dev target ATAPI device

u8 * r_sense_key out parameter for sense_key

Perform ATAPI TEST_UNIT_READY.

LOCKING: EH context (may sleep).

Return

0 on success, AC_ERR_* mask on failure.

void **ata_eh_request_sense**(struct ata_queued_cmd * qc, struct scsi_cmnd * cmd)
perform REQUEST_SENSE_DATA_EXT

Parameters

struct ata_queued_cmd * qc qc to perform REQUEST_SENSE_SENSE_DATA_EXT to

struct scsi_cmnd * cmd scsi command for which the sense code should be set

Perform REQUEST_SENSE_DATA_EXT after the device reported CHECK SENSE. This function is an EH helper.

LOCKING: Kernel thread context (may sleep).

unsigned int **atapi_eh_request_sense**(struct ata_device * dev, u8 * sense_buf, u8 dfl_sense_key)
perform ATAPI REQUEST_SENSE

Parameters

struct ata_device * dev device to perform REQUEST_SENSE to

u8 * sense_buf result sense data buffer (SCSI_SENSE_BUFFERSIZE bytes long)

u8 dfl_sense_key default sense key to use

Perform ATAPI REQUEST_SENSE after the device reported CHECK SENSE. This function is EH helper.

LOCKING: Kernel thread context (may sleep).

Return

0 on success, AC_ERR_* mask on failure

void **ata_eh_analyze_serror**(struct ata_link * link)
analyze SError for a failed port

Parameters

struct ata_link * link ATA link to analyze SError for

Analyze SError if available and further determine cause of failure.

LOCKING: None.

unsigned int **ata_eh_analyze_tf**(struct ata_queued_cmd * qc, const struct ata_taskfile * tf)
analyze taskfile of a failed qc

Parameters

struct ata_queued_cmd * qc qc to analyze

const struct ata_taskfile * tf Taskfile registers to analyze

Analyze taskfile of **qc** and further determine cause of failure. This function also requests ATAPI sense data if available.

LOCKING: Kernel thread context (may sleep).

Return

Determined recovery action

unsigned int **ata_eh_speed_down_verdict**(struct ata_device * dev)
Determine speed down verdict

Parameters

struct ata_device * dev Device of interest

This function examines error ring of **dev** and determines whether NCQ needs to be turned off, transfer speed should be stepped down, or falling back to PIO is necessary.

ECAT_ATA_BUS : ATA_BUS error for any command

ECAT_TOUT_HSM [TIMEOUT for any command or HSM violation for] IO commands

ECAT_UNK_DEV : Unknown DEV error for IO commands

ECAT_DUBIOUS_* [Identical to above three but occurred while] data transfer hasn't been verified.

Verdicts are

NCQ_OFF : Turn off NCQ.

SPEED_DOWN [Speed down transfer speed but don't fall back] to PIO.

FALLBACK_TO_PIO : Fall back to PIO.

Even if multiple verdicts are returned, only one action is taken per error. An action triggered by non-DUBIOUS errors clears ering, while one triggered by DUBIOUS_* errors doesn't. This is to expedite speed down decisions right after device is initially configured.

The following are speed down rules. #1 and #2 deal with DUBIOUS errors.

1. If more than one DUBIOUS_ATA_BUS or DUBIOUS_TOUT_HSM errors occurred during last 5 mins, SPEED_DOWN and FALLBACK_TO_PIO.
2. If more than one DUBIOUS_TOUT_HSM or DUBIOUS_UNK_DEV errors occurred during last 5 mins, NCQ_OFF.
3. If more than 8 ATA_BUS, TOUT_HSM or UNK_DEV errors occurred during last 5 mins, FALLBACK_TO_PIO
4. If more than 3 TOUT_HSM or UNK_DEV errors occurred during last 10 mins, NCQ_OFF.
5. If more than 3 ATA_BUS or TOUT_HSM errors, or more than 6 UNK_DEV errors occurred during last 10 mins, SPEED_DOWN.

LOCKING: Inherited from caller.

Return

OR of ATA_EH_SPDN_* flags.

unsigned int **ata_eh_speed_down**(struct ata_device * dev, unsigned int eflags, unsigned int err_mask)

record error and speed down if necessary

Parameters

struct ata_device * dev Failed device

unsigned int eflags mask of ATA_EFLAG_* flags

unsigned int err_mask err_mask of the error

Record error and examine error history to determine whether adjusting transmission speed is necessary. It also sets transmission limits appropriately if such adjustment is necessary.

LOCKING: Kernel thread context (may sleep).

Return

Determined recovery action.

int **ata_eh_worth_retry**(struct ata_queued_cmd * qc)
analyze error and decide whether to retry

Parameters

struct ata_queued_cmd * qc qc to possibly retry

Look at the cause of the error and decide if a retry might be useful or not. We don't want to retry media errors because the drive itself has probably already taken 10-30 seconds doing its own internal retries before reporting the failure.

bool **ata_eh_quiet**(struct ata_queued_cmd * qc)
check if we need to be quiet about a command error

Parameters

struct ata_queued_cmd * qc qc to check

Look at the qc flags anbd its scsi command request flags to determine if we need to be quiet about the command failure.

void **ata_eh_link_autopsy**(struct ata_link * link)
analyze error and determine recovery action

Parameters

struct ata_link * link host link to perform autopsy on

Analyze why **link** failed and determine which recovery actions are needed. This function also sets more detailed AC_ERR_* values and fills sense data for ATAPI CHECK SENSE.

LOCKING: Kernel thread context (may sleep).

void **ata_eh_autopsy**(struct ata_port * ap)
analyze error and determine recovery action

Parameters

struct ata_port * ap host port to perform autopsy on

Analyze all links of **ap** and determine why they failed and which recovery actions are needed.

LOCKING: Kernel thread context (may sleep).

const char * **ata_get_cmd_descript**(u8 command)
get description for ATA command

Parameters

u8 command ATA command code to get description for

Return a textual description of the given command, or NULL if the command is not known.

LOCKING: None

void **ata_eh_link_report**(struct ata_link * link)
report error handling to user

Parameters

struct ata_link * link ATA link EH is going on

Report EH to user.

LOCKING: None.

void **ata_eh_report**(struct ata_port * ap)
report error handling to user

Parameters

struct ata_port * ap ATA port to report EH about

Report EH to user.

LOCKING: None.

int **ata_set_mode**(struct ata_link * link, struct ata_device ** r_failed_dev)
Program timings and issue SET FEATURES - XFER

Parameters

struct ata_link * link link on which timings will be programmed

struct ata_device ** r_failed_dev out parameter for failed device

Set ATA device disk transfer mode (PIO3, UDMA6, etc.). If `ata_set_mode()` fails, pointer to the failing device is returned in **r_failed_dev**.

LOCKING: PCI/etc. bus probe sem.

Return

0 on success, negative errno otherwise

int **atapi_eh_clear_ua**(struct ata_device * dev)
Clear ATAPI UNIT ATTENTION after reset

Parameters

struct ata_device * dev ATAPI device to clear UA for

Resets and other operations can make an ATAPI device raise UNIT ATTENTION which causes the next operation to fail. This function clears UA.

LOCKING: EH context (may sleep).

Return

0 on success, -errno on failure.

int **ata_eh_maybe_retry_flush**(struct ata_device * dev)
Retry FLUSH if necessary

Parameters

struct ata_device * dev ATA device which may need FLUSH retry

If **dev** failed FLUSH, it needs to be reported upper layer immediately as it means that **dev** failed to remap and already lost at least a sector and further FLUSH retrials won't make any difference to the lost sector. However, if FLUSH failed for other reasons, for example transmission error, FLUSH needs to be retried.

This function determines whether FLUSH failure retry is necessary and performs it if so.

Return

0 if EH can continue, -errno if EH needs to be repeated.

int **ata_eh_set_lpm**(struct ata_link * link, enum ata_lpm_policy policy, struct ata_device ** r_failed_dev)
configure SATA interface power management

Parameters

struct ata_link * link link to configure power management

enum ata_lpm_policy policy the link power management policy

struct ata_device ** r_failed_dev out parameter for failed device

Enable SATA Interface power management. This will enable Device Interface Power Management (DIPM) for min_power and medium_power_with_dipm policies, and then call driver specific callbacks for enabling Host Initiated Power management.

LOCKING: EH context.

Return

0 on success, -errno on failure.

int **ata_eh_recover**(struct ata_port * ap, ata_prereset_fn_t prereset, ata_reset_fn_t softreset, ata_reset_fn_t hardreset, ata_postreset_fn_t postreset, struct ata_link ** r_failed_link)
recover host port after error

Parameters

struct ata_port * ap host port to recover

ata_prereset_fn_t prereset prereset method (can be NULL)

ata_reset_fn_t softreset softreset method (can be NULL)

ata_reset_fn_t hardreset hardreset method (can be NULL)

ata_postreset_fn_t postreset postreset method (can be NULL)

struct ata_link ** r_failed_link out parameter for failed link

This is the alpha and omega, eum and yang, heart and soul of libata exception handling. On entry, actions required to recover each link and hotplug requests are recorded in the link's eh_context. This function executes all the

operations with appropriate retrials and fallbacks to resurrect failed devices, detach goners and greet newcomers.

LOCKING: Kernel thread context (may sleep).

Return

0 on success, -errno on failure.

void **ata_eh_finish**(struct ata_port * ap)
finish up EH

Parameters

struct ata_port * ap host port to finish EH for

Recovery is complete. Clean up EH states and retry or finish failed qcs.

LOCKING: None.

void **ata_do_eh**(struct ata_port * ap, ata_prereset_fn_t prereset, ata_reset_fn_t softreset, ata_reset_fn_t hardreset, ata_postreset_fn_t postreset)
do standard error handling

Parameters

struct ata_port * ap host port to handle error for

ata_prereset_fn_t prereset prereset method (can be NULL)

ata_reset_fn_t softreset softreset method (can be NULL)

ata_reset_fn_t hardreset hardreset method (can be NULL)

ata_postreset_fn_t postreset postreset method (can be NULL)

Perform standard error handling sequence.

LOCKING: Kernel thread context (may sleep).

void **ata_std_error_handler**(struct ata_port * ap)
standard error handler

Parameters

struct ata_port * ap host port to handle error for

Standard error handler

LOCKING: Kernel thread context (may sleep).

void **ata_eh_handle_port_suspend**(struct ata_port * ap)
perform port suspend operation

Parameters

struct ata_port * ap port to suspend

Suspend **ap**.

LOCKING: Kernel thread context (may sleep).

void **ata_eh_handle_port_resume**(struct ata_port * ap)
perform port resume operation

Parameters

struct ata_port * ap port to resume

Resume **ap**.

LOCKING: Kernel thread context (may sleep).

33.6 libata SCSI translation/emulation

int **ata_std_bios_param**(struct scsi_device * sdev, struct block_device * bdev, sector_t capacity, int geom)
generic bios head/sector/cylinder calculator used by sd.

Parameters

struct scsi_device * sdev SCSI device for which BIOS geometry is to be determined

struct block_device * bdev block device associated with **sdev**

sector_t capacity capacity of SCSI device

int geom location to which geometry will be output

Generic bios head/sector/cylinder calculator used by sd. Most BIOSes nowadays expect a XXX/255/16 (CHS) mapping. Some situations may arise where the disk is not bootable if this is not used.

LOCKING: Defined by the SCSI layer. We don't really care.

Return

Zero.

void **ata_scsi_unlock_native_capacity**(struct scsi_device * sdev)
unlock native capacity

Parameters

struct scsi_device * sdev SCSI device to adjust device capacity for

This function is called if a partition on **sdev** extends beyond the end of the device. It requests EH to unlock HPA.

LOCKING: Defined by the SCSI layer. Might sleep.

bool **ata_scsi_dma_need_drain**(struct request * rq)
Check whether data transfer may overflow

Parameters

struct request * rq request to be checked

ATAPI commands which transfer variable length data to host might overflow due to application error or hardware bug. This function checks whether overflow should be drained and ignored for **request**.

LOCKING: None.

Return

1 if ; otherwise, 0.

int **ata_scsi_slave_config**(struct scsi_device * sdev)
Set SCSI device attributes

Parameters

struct scsi_device * sdev SCSI device to examine

This is called before we actually start reading and writing to the device, to configure certain SCSI mid-layer behaviors.

LOCKING: Defined by SCSI layer. We don't really care.

void **ata_scsi_slave_destroy**(struct scsi_device * sdev)
SCSI device is about to be destroyed

Parameters

struct scsi_device * sdev SCSI device to be destroyed

sdev is about to be destroyed for hot/warm unplugging. If this unplugging was initiated by libata as indicated by NULL dev->sdev, this function doesn't have to do anything. Otherwise, SCSI layer initiated warm-unplug is in progress. Clear dev->sdev, schedule the device for ATA detach and invoke EH.

LOCKING: Defined by SCSI layer. We don't really care.

int **ata_scsi_queuecmd**(struct Scsi_Host * shost, struct scsi_cmnd * cmd)
Issue SCSI cdb to libata-managed device

Parameters

struct Scsi_Host * shost SCSI host of command to be sent

struct scsi_cmnd * cmd SCSI command to be sent

In some cases, this function translates SCSI commands into ATA taskfiles, and queues the taskfiles to be sent to hardware. In other cases, this function simulates a SCSI device by evaluating and responding to certain SCSI commands. This creates the overall effect of ATA and ATAPI devices appearing as SCSI devices.

LOCKING: ATA host lock

Return

Return value from __ata_scsi_queuecmd() if **cmd** can be queued, 0 otherwise.

int **ata_get_identity**(struct ata_port * ap, struct scsi_device * sdev, void __user * arg)
Handler for HDIO_GET_IDENTITY ioctl

Parameters

struct ata_port * ap target port

struct scsi_device * sdev SCSI device to get identify data for

void __user * arg User buffer area for identify data

LOCKING: Defined by the SCSI layer. We don’t really care.

Return

Zero on success, negative errno on error.

int **ata_cmd_ioctl**(struct scsi_device * scsidev, void __user * arg)
Handler for HDIO_DRIVE_CMD ioctl

Parameters

struct scsi_device * scsidev Device to which we are issuing command

void __user * arg User provided data for issuing command

LOCKING: Defined by the SCSI layer. We don’t really care.

Return

Zero on success, negative errno on error.

int **ata_task_ioctl**(struct scsi_device * scsidev, void __user * arg)
Handler for HDIO_DRIVE_TASK ioctl

Parameters

struct scsi_device * scsidev Device to which we are issuing command

void __user * arg User provided data for issuing command

LOCKING: Defined by the SCSI layer. We don’t really care.

Return

Zero on success, negative errno on error.

struct ata_queued_cmd * **ata_scsi_qc_new**(struct ata_device * dev, struct scsi_cmnd * cmd)
acquire new ata_queued_cmd reference

Parameters

struct ata_device * dev ATA device to which the new command is attached

struct scsi_cmnd * cmd SCSI command that originated this ATA command

Obtain a reference to an unused ata_queued_cmd structure, which is the basic libata structure representing a single ATA command sent to the hardware.

If a command was available, fill in the SCSI-specific portions of the structure with information on the current command.

LOCKING: spin_lock_irqsave(host lock)

Return

Command allocated, or `NULL` if none available.

void **ata_dump_status**(unsigned id, struct ata_taskfile * tf)
user friendly display of error info

Parameters

unsigned id id of the port in question

struct ata_taskfile * tf ptr to filled out taskfile

Decode and dump the ATA error/status registers for the user so that they have some idea what really happened at the non make-believe layer.

LOCKING: inherited from caller

void **ata_to_sense_error**(unsigned id, u8 drv_stat, u8 drv_err, u8 * sk, u8 * asc, u8 * ascq, int verbose)
convert ATA error to SCSI error

Parameters

unsigned id ATA device number

u8 drv_stat value contained in ATA status register

u8 drv_err value contained in ATA error register

u8 * sk the sense key we'll fill out

u8 * asc the additional sense code we'll fill out

u8 * ascq the additional sense code qualifier we'll fill out

int verbose be verbose

Converts an ATA error into a SCSI error. Fill out pointers to SK, ASC, and ASCQ bytes for later use in fixed or descriptor format sense blocks.

LOCKING: spin_lock_irqsave(host lock)

void **ata_gen_ata_sense**(struct ata_queued_cmd * qc)
generate a SCSI fixed sense block

Parameters

struct ata_queued_cmd * qc Command that we are erroring out

Generate sense block for a failed ATA command **qc**. Descriptor format is used to accommodate LBA48 block address.

LOCKING: None.

unsigned int **ata_scsi_start_stop_xlat**(struct ata_queued_cmd * qc)
Translate SCSI START STOP UNIT command

Parameters

struct ata_queued_cmd * qc Storage for translated ATA taskfile

Sets up an ATA taskfile to issue STANDBY (to stop) or READ VERIFY (to start). Perhaps these commands should be preceded by CHECK POWER MODE to see what power mode the device is already in. [See SAT revision 5 at www.t10.org]

LOCKING: spin_lock_irqsave(host lock)

Return

Zero on success, non-zero on error.

unsigned int **ata_scsi_flush_xlat**(struct ata_queued_cmd * qc)
Translate SCSI SYNCHRONIZE CACHE command

Parameters

struct ata_queued_cmd * qc Storage for translated ATA taskfile

Sets up an ATA taskfile to issue FLUSH CACHE or FLUSH CACHE EXT.

LOCKING: spin_lock_irqsave(host lock)

Return

Zero on success, non-zero on error.

void **scsi_6_lba_len**(const u8 * cdb, u64 * plba, u32 * plen)
Get LBA and transfer length

Parameters

const u8 * cdb SCSI command to translate

Calculate LBA and transfer length for 6-byte commands.

u64 * plba the LBA

u32 * plen the transfer length

void **scsi_10_lba_len**(const u8 * cdb, u64 * plba, u32 * plen)
Get LBA and transfer length

Parameters

const u8 * cdb SCSI command to translate

Calculate LBA and transfer length for 10-byte commands.

u64 * plba the LBA

u32 * plen the transfer length

void **scsi_16_lba_len**(const u8 * cdb, u64 * plba, u32 * plen)
Get LBA and transfer length

Parameters

const u8 * cdb SCSI command to translate

Calculate LBA and transfer length for 16-byte commands.

u64 * plba the LBA

u32 * plen the transfer length

unsigned int **ata_scsi_verify_xlat**(struct ata_queued_cmd * qc)
Translate SCSI VERIFY command into an ATA one

Parameters

struct ata_queued_cmd * qc Storage for translated ATA taskfile

Converts SCSI VERIFY command to an ATA READ VERIFY command.

LOCKING: spin_lock_irqsave(host lock)

Return

Zero on success, non-zero on error.

unsigned int **ata_scsi_rw_xlat**(struct ata_queued_cmd * qc)
Translate SCSI r/w command into an ATA one

Parameters

struct ata_queued_cmd * qc Storage for translated ATA taskfile

Converts any of six SCSI read/write commands into the ATA counterpart, including starting sector (LBA), sector count, and taking into account the device's LBA48 support.

Commands `READ_6`, `READ_10`, `READ_16`, `WRITE_6`, `WRITE_10`, and `WRITE_16` are currently supported.

LOCKING: spin_lock_irqsave(host lock)

Return

Zero on success, non-zero on error.

int **ata_scsi_translate**(struct ata_device * dev, struct scsi_cmnd * cmd, ata_xlat_func_t xlat_func)
Translate then issue SCSI command to ATA device

Parameters

struct ata_device * dev ATA device to which the command is addressed

struct scsi_cmnd * cmd SCSI command to execute

ata_xlat_func_t xlat_func Actor which translates **cmd** to an ATA taskfile

Our ->queuecommand() function has decided that the SCSI command issued can be directly translated into an ATA command, rather than handled internally.

This function sets up an ata_queued_cmd structure for the SCSI command, and sends that ata_queued_cmd to the hardware.

The xlat_func argument (actor) returns 0 if ready to execute ATA command, else 1 to finish translation. If 1 is returned then cmd->result (and possibly cmd->sense_buffer) are assumed to be set reflecting an error condition or clean (early) termination.

LOCKING: spin_lock_irqsave(host lock)

Return

0 on success, SCSI_ML_QUEUE_DEVICE_BUSY if the command needs to be deferred.

void * **ata_scsi_rbuf_get**(struct scsi_cmnd * cmd, bool copy_in, unsigned long * flags)
Map response buffer.

Parameters

struct scsi_cmnd * cmd SCSI command containing buffer to be mapped.

bool copy_in copy in from user buffer

Prepare buffer for simulated SCSI commands.

LOCKING: spin_lock_irqsave(ata_scsi_rbuf_lock) on success

unsigned long * flags unsigned long variable to store irq enable status

Return

Pointer to response buffer.

void **ata_scsi_rbuf_put**(struct scsi_cmnd * cmd, bool copy_out, unsigned long * flags)

Unmap response buffer.

Parameters

struct scsi_cmnd * cmd SCSI command containing buffer to be unmapped.

bool copy_out copy out result

unsigned long * flags flags passed to `ata_scsi_rbuf_get()`

Returns rbuf buffer. The result is copied to **cmd**'s buffer if **copy_back** is true.

LOCKING: Unlocks ata_scsi_rbuf_lock.

void **ata_scsi_rbuf_fill**(struct ata_scsi_args * args, unsigned int (*actor)(struct ata_scsi_args *args, u8 *rbuf))

wrapper for SCSI command simulators

Parameters

struct ata_scsi_args * args device IDENTIFY data / SCSI command of interest.

unsigned int (*)(struct ata_scsi_args *args, u8 *rbuf) actor Callback hook for desired SCSI command simulator

Takes care of the hard work of simulating a SCSI command···Mapping the response buffer, calling the command's handler, and handling the handler's return value. This return value indicates whether the handler wishes the SCSI command to be completed successfully (0), or not (in which case cmd->result and sense buffer are assumed to be set).

LOCKING: spin_lock_irqsave(host lock)

unsigned int **ata_scsiop_inq_std**(struct ata_scsi_args * args, u8 * rbuf)

Simulate INQUIRY command

Parameters

struct ata_scsi_args * args device IDENTIFY data / SCSI command of interest.

u8 * rbuf Response buffer, to which simulated SCSI cmd output is sent.

Returns standard device identification data associated with non-VPD INQUIRY command output.

LOCKING: spin_lock_irqsave(host lock)

unsigned int **ata_scsiop_inq_00**(struct ata_scsi_args * args, u8 * rbuf)

Simulate INQUIRY VPD page 0, list of pages

Parameters

struct ata_scsi_args * args device IDENTIFY data / SCSI command of interest.

u8 * rbuf Response buffer, to which simulated SCSI cmd output is sent.

Returns list of inquiry VPD pages available.

LOCKING: spin_lock_irqsave(host lock)

unsigned int **ata_scsiop_inq_80**(struct ata_scsi_args * args, u8 * rbuf)
Simulate INQUIRY VPD page 80, device serial number

Parameters

struct ata_scsi_args * args device IDENTIFY data / SCSI command of interest.

u8 * rbuf Response buffer, to which simulated SCSI cmd output is sent.

Returns ATA device serial number.

LOCKING: spin_lock_irqsave(host lock)

unsigned int **ata_scsiop_inq_83**(struct ata_scsi_args * args, u8 * rbuf)
Simulate INQUIRY VPD page 83, device identity

Parameters

struct ata_scsi_args * args device IDENTIFY data / SCSI command of interest.

u8 * rbuf Response buffer, to which simulated SCSI cmd output is sent.

Yields two logical unit device identification designators:

- vendor specific ASCII containing the ATA serial number
- SAT defined "t10 vendor id based" containing ASCII vendor name ("ATA "), model and serial numbers.

LOCKING: spin_lock_irqsave(host lock)

unsigned int **ata_scsiop_inq_89**(struct ata_scsi_args * args, u8 * rbuf)
Simulate INQUIRY VPD page 89, ATA info

Parameters

struct ata_scsi_args * args device IDENTIFY data / SCSI command of interest.

u8 * rbuf Response buffer, to which simulated SCSI cmd output is sent.

Yields SAT-specified ATA VPD page.

LOCKING: spin_lock_irqsave(host lock)

void **modecpy**(u8 * dest, const u8 * src, int n, bool changeable)
Prepare response for MODE SENSE

Parameters

u8 * dest output buffer

const u8 * src data being copied

int n length of mode page

bool changeable whether changeable parameters are requested

Generate a generic MODE SENSE page for either current or changeable parameters.

LOCKING: None.

unsigned int **ata_msense_caching**(u16 * id, u8 * buf, bool changeable)
Simulate MODE SENSE caching info page

Parameters

u16 * id device IDENTIFY data

u8 * buf output buffer

bool changeable whether changeable parameters are requested

Generate a caching info page, which conditionally indicates write caching to the SCSI layer, depending on device capabilities.

LOCKING: None.

unsigned int **ata_msense_control**(struct ata_device * dev, u8 * buf, bool changeable)
Simulate MODE SENSE control mode page

Parameters

struct ata_device * dev ATA device of interest

u8 * buf output buffer

bool changeable whether changeable parameters are requested

Generate a generic MODE SENSE control mode page.

LOCKING: None.

unsigned int **ata_msense_rw_recovery**(u8 * buf, bool changeable)
Simulate MODE SENSE r/w error recovery page

Parameters

u8 * buf output buffer

bool changeable whether changeable parameters are requested

Generate a generic MODE SENSE r/w error recovery page.

LOCKING: None.

unsigned int **ata_scsiop_mode_sense**(struct ata_scsi_args * args, u8 * rbuf)
Simulate MODE SENSE 6, 10 commands

Parameters

struct ata_scsi_args * args device IDENTIFY data / SCSI command of interest.

u8 * rbuf Response buffer, to which simulated SCSI cmd output is sent.

Simulate MODE SENSE commands. Assume this is invoked for direct access devices (e.g. disks) only. There should be no block descriptor for other device types.

LOCKING: spin_lock_irqsave(host lock)

unsigned int **ata_scsiop_read_cap**(struct ata_scsi_args * args, u8 * rbuf)
Simulate READ CAPACITY[16] commands

Parameters

struct ata_scsi_args * args device IDENTIFY data / SCSI command of interest.

u8 * rbuf Response buffer, to which simulated SCSI cmd output is sent.

Simulate READ CAPACITY commands.

LOCKING: None.

unsigned int **ata_scsiop_report_luns**(struct ata_scsi_args * args, u8 * rbuf)
Simulate REPORT LUNS command

Parameters

struct ata_scsi_args * args device IDENTIFY data / SCSI command of interest.

u8 * rbuf Response buffer, to which simulated SCSI cmd output is sent.

Simulate REPORT LUNS command.

LOCKING: spin_lock_irqsave(host lock)

unsigned int **atapi_xlat**(struct ata_queued_cmd * qc)
Initialize PACKET taskfile

Parameters

struct ata_queued_cmd * qc command structure to be initialized

LOCKING: spin_lock_irqsave(host lock)

Return

Zero on success, non-zero on failure.

struct ata_device * **ata_scsi_find_dev**(struct ata_port * ap, const struct scsi_device * scsidev)
lookup ata_device from scsi_cmnd

Parameters

struct ata_port * ap ATA port to which the device is attached

const struct scsi_device * scsidev SCSI device from which we derive the ATA device

Given various information provided in struct scsi_cmnd, map that onto an ATA bus, and using that mapping determine which ata_device is associated with the SCSI command to be sent.

LOCKING: spin_lock_irqsave(host lock)

Return

Associated ATA device, or NULL if not found.

unsigned int **ata_scsi_pass_thru**(struct ata_queued_cmd * qc)
convert ATA pass-thru CDB to taskfile

Parameters

struct ata_queued_cmd * qc command structure to be initialized

Handles either 12, 16, or 32-byte versions of the CDB.

Return

Zero on success, non-zero on failure.

size_t **ata_format_dsm_trim_descr**(struct scsi_cmnd * cmd, u32 trmax, u64 sector, u32 count)
SATL Write Same to DSM Trim

Parameters

struct scsi_cmnd * cmd SCSI command being translated

u32 trmax Maximum number of entries that will fit in sector_size bytes.

u64 sector Starting sector

u32 count Total Range of request in logical sectors

Description

Rewrite the WRITE SAME descriptor to be a DSM TRIM little-endian formatted descriptor.

Upto 64 entries of the format:

63:48 Range Length 47:0 LBA

Range Length of 0 is ignored. LBA's should be sorted order and not overlap.

NOTE

this is the same format as ADD LBA(S) TO NV CACHE PINNED SET

Return

Number of bytes copied into sglist.

unsigned int **ata_scsi_write_same_xlat**(struct ata_queued_cmd * qc)
SATL Write Same to ATA SCT Write Same

Parameters

struct ata_queued_cmd * qc Command to be translated

Description

Translate a SCSI WRITE SAME command to be either a DSM TRIM command or an SCT Write Same command. Based on WRITE SAME has the UNMAP flag:

- When set translate to DSM TRIM

- When clear translate to SCT Write Same

unsigned int **ata_scsiop_maint_in**(struct ata_scsi_args * args, u8 * rbuf)
Simulate a subset of MAINTENANCE_IN

Parameters

struct ata_scsi_args * args device MAINTENANCE_IN data / SCSI command of interest.

u8 * rbuf Response buffer, to which simulated SCSI cmd output is sent.

Yields a subset to satisfy `scsi_report_opcode()`

LOCKING: spin_lock_irqsave(host lock)

void **ata_scsi_report_zones_complete**(struct ata_queued_cmd * qc)
convert ATA output

Parameters

struct ata_queued_cmd * qc command structure returning the data

Convert T-13 little-endian field representation into T-10 big-endian field representation. What a mess.

int **ata_mselect_caching**(struct ata_queued_cmd * qc, const u8 * buf, int len, u16 * fp)
Simulate MODE SELECT for caching info page

Parameters

struct ata_queued_cmd * qc Storage for translated ATA taskfile

const u8 * buf input buffer

int len number of valid bytes in the input buffer

u16 * fp out parameter for the failed field on error

Prepare a taskfile to modify caching information for the device.

LOCKING: None.

int **ata_mselect_control**(struct ata_queued_cmd * qc, const u8 * buf, int len, u16 * fp)
Simulate MODE SELECT for control page

Parameters

struct ata_queued_cmd * qc Storage for translated ATA taskfile

const u8 * buf input buffer

int len number of valid bytes in the input buffer

u16 * fp out parameter for the failed field on error

Prepare a taskfile to modify caching information for the device.

LOCKING: None.

unsigned int **ata_scsi_mode_select_xlat**(struct ata_queued_cmd * qc)
Simulate MODE SELECT 6, 10 commands

Parameters

struct ata_queued_cmd * qc Storage for translated ATA taskfile

Converts a MODE SELECT command to an ATA SET FEATURES taskfile. Assume this is invoked for direct access devices (e.g. disks) only. There should be no block descriptor for other device types.

LOCKING: spin_lock_irqsave(host lock)

unsigned int **ata_scsi_var_len_cdb_xlat**(struct ata_queued_cmd * qc)
SATL variable length CDB to Handler

Parameters

struct ata_queued_cmd * qc Command to be translated

Translate a SCSI variable length CDB to specified commands. It checks a service action value in CDB to call corresponding handler.

Return

Zero on success, non-zero on failure

ata_xlat_func_t **ata_get_xlat_func**(struct ata_device * dev, u8 cmd)
check if SCSI to ATA translation is possible

Parameters

struct ata_device * dev ATA device

u8 cmd SCSI command opcode to consider

Look up the SCSI command given, and determine whether the SCSI command is to be translated or simulated.

Return

Pointer to translation function if possible, `NULL` if not.

void **ata_scsi_dump_cdb**(struct ata_port * ap, struct scsi_cmnd * cmd)
dump SCSI command contents to dmesg

Parameters

struct ata_port * ap ATA port to which the command was being sent

struct scsi_cmnd * cmd SCSI command to dump

Prints the contents of a SCSI command via `printk()`.

void **ata_scsi_simulate**(struct ata_device * dev, struct scsi_cmnd * cmd)
simulate SCSI command on ATA device

Parameters

struct ata_device * dev the target device

struct scsi_cmnd * cmd SCSI command being sent to device.

Interprets and directly executes a select list of SCSI commands that can be handled internally.

LOCKING: spin_lock_irqsave(host lock)

int **ata_scsi_offline_dev**(struct ata_device * dev)
offline attached SCSI device

Parameters

struct ata_device * dev ATA device to offline attached SCSI device for

This function is called from ata_eh_hotplug() and responsible for taking the SCSI device attached to **dev** offline. This function is called with host lock which protects dev->sdev against clearing.

LOCKING: spin_lock_irqsave(host lock)

Return

1 if attached SCSI device exists, 0 otherwise.

void **ata_scsi_remove_dev**(struct ata_device * dev)
remove attached SCSI device

Parameters

struct ata_device * dev ATA device to remove attached SCSI device for

This function is called from ata_eh_scsi_hotplug() and responsible for removing the SCSI device attached to **dev**.

LOCKING: Kernel thread context (may sleep).

void **ata_scsi_media_change_notify**(struct ata_device * dev)
send media change event

Parameters

struct ata_device * dev Pointer to the disk device with media change event

Tell the block layer to send a media change notification event.

LOCKING: spin_lock_irqsave(host lock)

void **ata_scsi_hotplug**(struct work_struct * work)
SCSI part of hotplug

Parameters

struct work_struct * work Pointer to ATA port to perform SCSI hotplug on

Perform SCSI part of hotplug. It' s executed from a separate workqueue after EH completes. This is necessary because SCSI hot plugging requires working EH and hot unplugging is synchronized with hot plugging with a mutex.

LOCKING: Kernel thread context (may sleep).

int **ata_scsi_user_scan**(struct Scsi_Host * shost, unsigned int channel, unsigned int id, u64 lun)
indication for user-initiated bus scan

Parameters

struct Scsi_Host * shost SCSI host to scan

unsigned int channel Channel to scan

unsigned int id ID to scan

u64 lun LUN to scan

This function is called when user explicitly requests bus scan. Set probe pending flag and invoke EH.

LOCKING: SCSI layer (we don't care)

Return

Zero.

void **ata_scsi_dev_rescan**(struct work_struct * work)
initiate scsi_rescan_device()

Parameters

struct work_struct * work Pointer to ATA port to perform scsi_rescan_device()

After ATA pass thru (SAT) commands are executed successfully, libata need to propagate the changes to SCSI layer.

LOCKING: Kernel thread context (may sleep).

33.7 ATA errors and exceptions

This chapter tries to identify what error/exception conditions exist for ATA/ATAPI devices and describe how they should be handled in implementation-neutral way.

The term 'error' is used to describe conditions where either an explicit error condition is reported from device or a command has timed out.

The term 'exception' is either used to describe exceptional conditions which are not errors (say, power or hotplug events), or to describe both errors and non-error exceptional conditions. Where explicit distinction between error and exception is necessary, the term 'non-error exception' is used.

33.7.1 Exception categories

Exceptions are described primarily with respect to legacy taskfile + bus master IDE interface. If a controller provides other better mechanism for error reporting, mapping those into categories described below shouldn't be difficult.

In the following sections, two recovery actions - reset and reconfiguring transport - are mentioned. These are described further in EH recovery actions.

HSM violation

This error is indicated when STATUS value doesn't match HSM requirement during issuing or execution any ATA/ATAPI command.

- ATA_STATUS doesn't contain !BSY && DRDY && !DRQ while trying to issue a command.
- !BSY && !DRQ during PIO data transfer.
- DRQ on command completion.

- !BSY && ERR after CDB transfer starts but before the last byte of CDB is transferred. ATA/ATAPI standard states that "The device shall not terminate the PACKET command with an error before the last byte of the command packet has been written"in the error outputs description of PACKET command and the state diagram doesn't include such transitions.

In these cases, HSM is violated and not much information regarding the error can be acquired from STATUS or ERROR register. IOW, this error can be anything - driver bug, faulty device, controller and/or cable.

As HSM is violated, reset is necessary to restore known state. Reconfiguring transport for lower speed might be helpful too as transmission errors sometimes cause this kind of errors.

ATA/ATAPI device error (non-NCQ / non-CHECK CONDITION)

These are errors detected and reported by ATA/ATAPI devices indicating device problems. For this type of errors, STATUS and ERROR register values are valid and describe error condition. Note that some of ATA bus errors are detected by ATA/ATAPI devices and reported using the same mechanism as device errors. Those cases are described later in this section.

For ATA commands, this type of errors are indicated by !BSY && ERR during command execution and on completion.

For ATAPI commands,

- !BSY && ERR && ABRT right after issuing PACKET indicates that PACKET command is not supported and falls in this category.
- !BSY && ERR(==CHK) && !ABRT after the last byte of CDB is transferred indicates CHECK CONDITION and doesn't fall in this category.
- !BSY && ERR(==CHK) && ABRT after the last byte of CDB is transferred *probably* indicates CHECK CONDITION and doesn't fall in this category.

Of errors detected as above, the following are not ATA/ATAPI device errors but ATA bus errors and should be handled according to ATA bus error.

CRC error during data transfer This is indicated by ICRC bit in the ERROR register and means that corruption occurred during data transfer. Up to ATA/ATAPI-7, the standard specifies that this bit is only applicable to UDMA transfers but ATA/ATAPI-8 draft revision 1f says that the bit may be applicable to multiword DMA and PIO.

ABRT error during data transfer or on completion Up to ATA/ATAPI-7, the standard specifies that ABRT could be set on ICRC errors and on cases where a device is not able to complete a command. Combined with the fact that MWDMA and PIO transfer errors aren't allowed to use ICRC bit up to ATA/ATAPI-7, it seems to imply that ABRT bit alone could indicate transfer errors.

However, ATA/ATAPI-8 draft revision 1f removes the part that ICRC errors can turn on ABRT. So, this is kind of gray area. Some heuristics are needed here.

ATA/ATAPI device errors can be further categorized as follows.

Media errors This is indicated by UNC bit in the ERROR register. ATA devices reports UNC error only after certain number of retries cannot recover the data, so there's nothing much else to do other than notifying upper layer.

READ and WRITE commands report CHS or LBA of the first failed sector but ATA/ATAPI standard specifies that the amount of transferred data on error completion is indeterminate, so we cannot assume that sectors preceding the failed sector have been transferred and thus cannot complete those sectors successfully as SCSI does.

Media changed / media change requested error <<TODO: fill here>>

Address error This is indicated by IDNF bit in the ERROR register. Report to upper layer.

Other errors This can be invalid command or parameter indicated by ABRT ERROR bit or some other error condition. Note that ABRT bit can indicate a lot of things including ICRC and Address errors. Heuristics needed.

Depending on commands, not all STATUS/ERROR bits are applicable. These non-applicable bits are marked with "na"in the output descriptions but up to ATA/ATAPI-7 no definition of "na" can be found. However, ATA/ATAPI-8 draft revision 1f describes "N/A" as follows.

> **3.2.3.3a N/A** A keyword the indicates a field has no defined value in this standard and should not be checked by the host or device. N/A fields should be cleared to zero.

So, it seems reasonable to assume that "na" bits are cleared to zero by devices and thus need no explicit masking.

ATAPI device CHECK CONDITION

ATAPI device CHECK CONDITION error is indicated by set CHK bit (ERR bit) in the STATUS register after the last byte of CDB is transferred for a PACKET command. For this kind of errors, sense data should be acquired to gather information regarding the errors. REQUEST SENSE packet command should be used to acquire sense data.

Once sense data is acquired, this type of errors can be handled similarly to other SCSI errors. Note that sense data may indicate ATA bus error (e.g. Sense Key 04h HARDWARE ERROR && ASC/ASCQ 47h/00h SCSI PARITY ERROR). In such cases, the error should be considered as an ATA bus error and handled according to ATA bus error.

ATA device error (NCQ)

NCQ command error is indicated by cleared BSY and set ERR bit during NCQ command phase (one or more NCQ commands outstanding). Although STATUS and ERROR registers will contain valid values describing the error, READ LOG EXT is required to clear the error condition, determine which command has failed and acquire more information.

READ LOG EXT Log Page 10h reports which tag has failed and taskfile register values describing the error. With this information the failed command can be handled as a normal ATA command error as in ATA/ATAPI device error (non-NCQ / non-CHECK CONDITION) and all other in-flight commands must be retried. Note that this retry should not be counted - it's likely that commands retried this way would have completed normally if it were not for the failed command.

Note that ATA bus errors can be reported as ATA device NCQ errors. This should be handled as described in ATA bus error.

If READ LOG EXT Log Page 10h fails or reports NQ, we're thoroughly screwed. This condition should be treated according to HSM violation.

ATA bus error

ATA bus error means that data corruption occurred during transmission over ATA bus (SATA or PATA). This type of errors can be indicated by

- ICRC or ABRT error as described in ATA/ATAPI device error (non-NCQ / non-CHECK CONDITION).
- Controller-specific error completion with error information indicating transmission error.
- On some controllers, command timeout. In this case, there may be a mechanism to determine that the timeout is due to transmission error.
- Unknown/random errors, timeouts and all sorts of weirdities.

As described above, transmission errors can cause wide variety of symptoms ranging from device ICRC error to random device lockup, and, for many cases, there is no way to tell if an error condition is due to transmission error or not; therefore, it's necessary to employ some kind of heuristic when dealing with errors and timeouts. For example, encountering repetitive ABRT errors for known supported command is likely to indicate ATA bus error.

Once it's determined that ATA bus errors have possibly occurred, lowering ATA bus transmission speed is one of actions which may alleviate the problem. See Reconfigure transport for more information.

PCI bus error

Data corruption or other failures during transmission over PCI (or other system bus). For standard BMDMA, this is indicated by Error bit in the BMDMA Status register. This type of errors must be logged as it indicates something is very wrong with the system. Resetting host controller is recommended.

Late completion

This occurs when timeout occurs and the timeout handler finds out that the timed out command has completed successfully or with error. This is usually caused by lost interrupts. This type of errors must be logged. Resetting host controller is recommended.

Unknown error (timeout)

This is when timeout occurs and the command is still processing or the host and device are in unknown state. When this occurs, HSM could be in any valid or invalid state. To bring the device to known state and make it forget about the timed out command, resetting is necessary. The timed out command may be retried.

Timeouts can also be caused by transmission errors. Refer to ATA bus error for more details.

Hotplug and power management exceptions

<<TODO: fill here>>

33.7.2 EH recovery actions

This section discusses several important recovery actions.

Clearing error condition

Many controllers require its error registers to be cleared by error handler. Different controllers may have different requirements.

For SATA, it' s strongly recommended to clear at least SError register during error handling.

Reset

During EH, resetting is necessary in the following cases.

- HSM is in unknown or invalid state
- HBA is in unknown or invalid state
- EH needs to make HBA/device forget about in-flight commands
- HBA/device behaves weirdly

Resetting during EH might be a good idea regardless of error condition to improve EH robustness. Whether to reset both or either one of HBA and device depends on situation but the following scheme is recommended.

- When it's known that HBA is in ready state but ATA/ATAPI device is in unknown state, reset only device.
- If HBA is in unknown state, reset both HBA and device.

HBA resetting is implementation specific. For a controller complying to taskfile/BMDMA PCI IDE, stopping active DMA transaction may be sufficient iff BMDMA state is the only HBA context. But even mostly taskfile/BMDMA PCI IDE complying controllers may have implementation specific requirements and mechanism to reset themselves. This must be addressed by specific drivers.

OTOH, ATA/ATAPI standard describes in detail ways to reset ATA/ATAPI devices.

PATA hardware reset This is hardware initiated device reset signalled with asserted PATA RESET- signal. There is no standard way to initiate hardware reset from software although some hardware provides registers that allow driver to directly tweak the RESET- signal.

Software reset This is achieved by turning CONTROL SRST bit on for at least 5us. Both PATA and SATA support it but, in case of SATA, this may require controller-specific support as the second Register FIS to clear SRST should be transmitted while BSY bit is still set. Note that on PATA, this resets both master and slave devices on a channel.

EXECUTE DEVICE DIAGNOSTIC command Although ATA/ATAPI standard doesn't describe exactly, EDD implies some level of resetting, possibly similar level with software reset. Host-side EDD protocol can be handled with normal command processing and most SATA controllers should be able to handle EDD's just like other commands. As in software reset, EDD affects both devices on a PATA bus.

Although EDD does reset devices, this doesn't suit error handling as EDD cannot be issued while BSY is set and it's unclear how it will act when device is in unknown/weird state.

ATAPI DEVICE RESET command This is very similar to software reset except that reset can be restricted to the selected device without affecting the other device sharing the cable.

SATA phy reset This is the preferred way of resetting a SATA device. In effect, it's identical to PATA hardware reset. Note that this can be done with the standard SCR Control register. As such, it's usually easier to implement than software reset.

One more thing to consider when resetting devices is that resetting clears certain configuration parameters and they need to be set to their previous or newly adjusted values after reset.

Parameters affected are.

- CHS set up with INITIALIZE DEVICE PARAMETERS (seldom used)
- Parameters set with SET FEATURES including transfer mode setting
- Block count set with SET MULTIPLE MODE
- Other parameters (SET MAX, MEDIA LOCK…)

ATA/ATAPI standard specifies that some parameters must be maintained across hardware or software reset, but doesn't strictly specify all of them. Always reconfiguring needed parameters after reset is required for robustness. Note that this also applies when resuming from deep sleep (power-off).

Also, ATA/ATAPI standard requires that IDENTIFY DEVICE / IDENTIFY PACKET DEVICE is issued after any configuration parameter is updated or a hardware reset and the result used for further operation. OS driver is required to implement revalidation mechanism to support this.

Reconfigure transport

For both PATA and SATA, a lot of corners are cut for cheap connectors, cables or controllers and it's quite common to see high transmission error rate. This can be mitigated by lowering transmission speed.

The following is a possible scheme Jeff Garzik suggested.

> If more than $N (3?) transmission errors happen in 15 minutes,
>
> - if SATA, decrease SATA PHY speed. if speed cannot be decreased,
> - decrease UDMA xfer speed. if at UDMA0, switch to PIO4,
> - decrease PIO xfer speed. if at PIO3, complain, but continue

33.8 ata_piix Internals

int **ich_pata_cable_detect**(struct ata_port * ap)
Probe host controller cable detect info

Parameters

struct ata_port * ap Port for which cable detect info is desired

Read 80c cable indicator from ATA PCI device's PCI config register. This register is normally set by firmware (BIOS).

LOCKING: None (inherited from caller).

int **piix_pata_prereset**(struct ata_link * link, unsigned long deadline)
prereset for PATA host controller

Parameters

struct ata_link * link Target link

unsigned long deadline deadline jiffies for the operation

LOCKING: None (inherited from caller).

void **piix_set_piomode**(struct ata_port * ap, struct ata_device * adev)
Initialize host controller PATA PIO timings

Parameters

struct ata_port * ap Port whose timings we are configuring

struct ata_device * adev Drive in question

Set PIO mode for device, in host controller PCI config space.

LOCKING: None (inherited from caller).

void **do_pata_set_dmamode**(struct ata_port * ap, struct ata_device * adev, int isich)
Initialize host controller PATA PIO timings

Parameters

struct ata_port * ap Port whose timings we are configuring

struct ata_device * adev Drive in question

int isich set if the chip is an ICH device

Set UDMA mode for device, in host controller PCI config space.

LOCKING: None (inherited from caller).

void **piix_set_dmamode**(struct ata_port * ap, struct ata_device * adev)
Initialize host controller PATA DMA timings

Parameters

struct ata_port * ap Port whose timings we are configuring

struct ata_device * adev um

Set MW/UDMA mode for device, in host controller PCI config space.

LOCKING: None (inherited from caller).

void **ich_set_dmamode**(struct ata_port * ap, struct ata_device * adev)
Initialize host controller PATA DMA timings

Parameters

struct ata_port * ap Port whose timings we are configuring

struct ata_device * adev um

Set MW/UDMA mode for device, in host controller PCI config space.

LOCKING: None (inherited from caller).

int **piix_check_450nx_errata**(struct pci_dev * ata_dev)
Check for problem 450NX setup

Parameters

struct pci_dev * ata_dev the PCI device to check

Check for the present of 450NX errata #19 and errata #25. If they are found return an error code so we can turn off DMA

int **piix_init_one**(struct pci_dev * pdev, const struct pci_device_id * ent)
Register PIIX ATA PCI device with kernel services

Parameters

struct pci_dev * pdev PCI device to register

const struct pci_device_id * ent Entry in piix_pci_tbl matching with **pdev**

Called from kernel PCI layer. We probe for combined mode (sigh), and then hand over control to libata, for it to do the rest.

LOCKING: Inherited from PCI layer (may sleep).

Return

Zero on success, or -ERRNO value.

33.9 sata_sil Internals

int **sil_set_mode**(struct ata_link * link, struct ata_device ** r_failed)
wrap set_mode functions

Parameters

struct ata_link * link link to set up

struct ata_device ** r_failed returned device when we fail

Wrap the libata method for device setup as after the setup we need to inspect the results and do some configuration work

void **sil_dev_config**(struct ata_device * dev)
Apply device/host-specific errata fixups

Parameters

struct ata_device * dev Device to be examined

After the IDENTIFY [PACKET] DEVICE step is complete, and a device is known to be present, this function is called. We apply two errata fixups which are specific to Silicon Image, a Seagate and a Maxtor fixup.

For certain Seagate devices, we must limit the maximum sectors to under 8K.

For certain Maxtor devices, we must not program the drive beyond udma5.

Both fixups are unfairly pessimistic. As soon as I get more information on these errata, I will create a more exhaustive list, and apply the fixups to only the specific devices/hosts/firmwares that need it.

20040111 - Seagate drives affected by the Mod15Write bug are blacklisted The Maxtor quirk is in the blacklist, but I'm keeping the original pessimistic fix for the following reasons···- There seems to be less info on it, only one device gleaned off the Windows driver, maybe only one is affected. More info

would be greatly appreciated. - But then again UDMA5 is hardly anything to complain about

33.10 Thanks

The bulk of the ATA knowledge comes thanks to long conversations with Andre Hedrick (www.linux-ide.org), and long hours pondering the ATA and SCSI specifications.

Thanks to Alan Cox for pointing out similarities between SATA and SCSI, and in general for motivation to hack on libata.

libata's device detection method, ata_pio_devchk, and in general all the early probing was based on extensive study of Hale Landis's probe/reset code in his ATADRVR driver (www.ata-atapi.com).

CHAPTER

THIRTYFOUR

TARGET AND ISCSI INTERFACES GUIDE

34.1 Introduction and Overview

TBD

34.2 Target core device interfaces

This section is blank because no kerneldoc comments have been added to drivers/target/target_core_device.c.

34.3 Target core transport interfaces

int **transport_init_session**(struct se_session * se_sess)
initialize a session object

Parameters

struct se_session * se_sess Session object pointer.

Description

The caller must have zero-initialized **se_sess** before calling this function.

struct se_session * **transport_alloc_session**(enum target_prot_op sup_prot_ops)
allocate a session object and initialize it

Parameters

enum target_prot_op sup_prot_ops bitmask that defines which T10-PI modes are supported.

int **transport_alloc_session_tags**(struct se_session * se_sess, unsigned int tag_num, unsigned int tag_size)
allocate target driver private data

Parameters

struct se_session * se_sess Session pointer.

unsigned int tag_num Maximum number of in-flight commands between initiator and target.

unsigned int tag_size Size in bytes of the private data a target driver associates with each command.

int **target_submit_cmd_map_sgls**(struct se_cmd * se_cmd, struct se_session * se_sess, unsigned char * cdb, unsigned char * sense, u64 unpacked_lun, u32 data_length, int task_attr, int data_dir, int flags, struct scatterlist * sgl, u32 sgl_count, struct scatterlist * sgl_bidi, u32 sgl_bidi_count, struct scatterlist * sgl_prot, u32 sgl_prot_count)

lookup unpacked lun and submit uninitialized se_cmd + use pre-allocated SGL memory.

Parameters

struct se_cmd * se_cmd command descriptor to submit

struct se_session * se_sess associated se_sess for endpoint

unsigned char * cdb pointer to SCSI CDB

unsigned char * sense pointer to SCSI sense buffer

u64 unpacked_lun unpacked LUN to reference for struct se_lun

u32 data_length fabric expected data transfer length

int task_attr SAM task attribute

int data_dir DMA data direction

int flags flags for command submission from target_sc_flags_tables

struct scatterlist * sgl struct scatterlist memory for unidirectional mapping

u32 sgl_count scatterlist count for unidirectional mapping

struct scatterlist * sgl_bidi struct scatterlist memory for bidirectional READ mapping

u32 sgl_bidi_count scatterlist count for bidirectional READ mapping

struct scatterlist * sgl_prot struct scatterlist memory protection information

u32 sgl_prot_count scatterlist count for protection information

Description

Task tags are supported if the caller has set **se_cmd->tag**.

Returns non zero to signal active I/O shutdown failure. All other setup exceptions will be returned as a SCSI CHECK_CONDITION response, but still return zero here.

This may only be called from process context, and also currently assumes internal allocation of fabric payload buffer by target-core.

int **target_submit_cmd**(struct se_cmd * se_cmd, struct se_session * se_sess, unsigned char * cdb, unsigned char * sense, u64 unpacked_lun, u32 data_length, int task_attr, int data_dir, int flags)

lookup unpacked lun and submit uninitialized se_cmd

Parameters

struct se_cmd * se_cmd command descriptor to submit

struct se_session * se_sess associated se_sess for endpoint

unsigned char * cdb pointer to SCSI CDB

unsigned char * sense pointer to SCSI sense buffer

u64 unpacked_lun unpacked LUN to reference for struct se_lun

u32 data_length fabric expected data transfer length

int task_attr SAM task attribute

int data_dir DMA data direction

int flags flags for command submission from target_sc_flags_tables

Description

Task tags are supported if the caller has set **se_cmd->tag**.

Returns non zero to signal active I/O shutdown failure. All other setup exceptions will be returned as a SCSI CHECK_CONDITION response, but still return zero here.

This may only be called from process context, and also currently assumes internal allocation of fabric payload buffer by target-core.

It also assumes interal target core SGL memory allocation.

int **target_submit_tmr**(struct se_cmd * se_cmd, struct se_session * se_sess, unsigned char * sense, u64 unpacked_lun, void * fabric_tmr_ptr, unsigned char tm_type, gfp_t gfp, u64 tag, int flags)

lookup unpacked lun and submit uninitialized se_cmd for TMR CDBs

Parameters

struct se_cmd * se_cmd command descriptor to submit

struct se_session * se_sess associated se_sess for endpoint

unsigned char * sense pointer to SCSI sense buffer

u64 unpacked_lun unpacked LUN to reference for struct se_lun

void * fabric_tmr_ptr fabric context for TMR req

unsigned char tm_type Type of TM request

gfp_t gfp gfp type for caller

u64 tag referenced task tag for TMR_ABORT_TASK

int flags submit cmd flags

Description

Callable from all contexts.

int **target_get_sess_cmd**(struct se_cmd * se_cmd, bool ack_kref)
Add command to active ->sess_cmd_list

Parameters

struct se_cmd * se_cmd command descriptor to add

bool ack_kref Signal that fabric will perform an ack `target_put_sess_cmd()`

int **target_put_sess_cmd**(struct se_cmd * se_cmd)
decrease the command reference count

Parameters

struct se_cmd * se_cmd command to drop a reference from

Description

Returns 1 if and only if this `target_put_sess_cmd()` call caused the refcount to drop to zero. Returns zero otherwise.

void **target_sess_cmd_list_set_waiting**(struct se_session * se_sess)
Set sess_tearing_down so no new commands are queued.

Parameters

struct se_session * se_sess session to flag

void **target_wait_for_sess_cmds**(struct se_session * se_sess)
Wait for outstanding commands

Parameters

struct se_session * se_sess session to wait for active I/O

bool **transport_wait_for_tasks**(struct se_cmd * cmd)
set CMD_T_STOP and wait for t_transport_stop_comp

Parameters

struct se_cmd * cmd command to wait on

int **target_send_busy**(struct se_cmd * cmd)
Send SCSI BUSY status back to the initiator

Parameters

struct se_cmd * cmd SCSI command for which to send a BUSY reply.

Note

Only call this function if target_submit_cmd*() failed.

34.4 Target-supported userspace I/O

34.4.1 Userspace I/O

Define a shared-memory interface for LIO to pass SCSI commands and data to userspace for processing. This is to allow backends that are too complex for in-kernel support to be possible.

It uses the UIO framework to do a lot of the device-creation and introspection work for us.

See the .h file for how the ring is laid out. Note that while the command ring is defined, the particulars of the data area are not. Offset values in the command entry point to other locations internal to the mmap-ed area. There is separate space outside the command ring for data buffers. This leaves maximum flexibility for moving buffer allocations, or even page flipping or other allocation techniques, without altering the command ring layout.

SECURITY: The user process must be assumed to be malicious. There's no way to prevent it breaking the command ring protocol if it wants, but in order to prevent other issues we must only ever read data from the shared memory area, not offsets or sizes. This applies to command ring entries as well as the mailbox. Extra code needed for this may have a 'UAM' comment.

34.4.2 Ring Design

The mmaped area is divided into three parts: 1) The mailbox (struct tcmu_mailbox, below); 2) The command ring; 3) Everything beyond the command ring (data).

The mailbox tells userspace the offset of the command ring from the start of the shared memory region, and how big the command ring is.

The kernel passes SCSI commands to userspace by putting a struct tcmu_cmd_entry in the ring, updating mailbox->cmd_head, and poking userspace via UIO's interrupt mechanism.

tcmu_cmd_entry contains a header. If the header type is PAD, userspace should skip hdr->length bytes (mod cmdr_size) to find the next cmd_entry.

Otherwise, the entry will contain offsets into the mmaped area that contain the cdb and data buffers – the latter accessible via the iov array. iov addresses are also offsets into the shared area.

When userspace is completed handling the command, set entry->rsp.scsi_status, fill in rsp.sense_buffer if appropriate, and also set mailbox->cmd_tail equal to the old cmd_tail plus hdr->length, mod cmdr_size. If cmd_tail doesn't equal cmd_head, it should process the next packet the same way, and so on.

34.5 iSCSI helper functions

void **iscsi_prep_data_out_pdu**(struct iscsi_task * task, struct iscsi_r2t_info * r2t, struct iscsi_data * hdr)
initialize Data-Out

Parameters

struct iscsi_task * task scsi command task

struct iscsi_r2t_info * r2t R2T info

struct iscsi_data * hdr iscsi data in pdu

Notes

Initialize Data-Out within this R2T sequence and finds proper data_offset within this SCSI command.

This function is called with connection lock taken.

void **iscsi_complete_scsi_task**(struct iscsi_task * task, uint32_t exp_cmdsn, uint32_t max_cmdsn)
finish scsi task normally

Parameters

struct iscsi_task * task iscsi task for scsi cmd

uint32_t exp_cmdsn expected cmd sn in cpu format

uint32_t max_cmdsn max cmd sn in cpu format

Description

This is used when drivers do not need or cannot perform lower level pdu processing.

Called with session back_lock

struct iscsi_task * **iscsi_itt_to_task**(struct iscsi_conn * conn, itt_t itt)
look up task by itt

Parameters

struct iscsi_conn * conn iscsi connection

itt_t itt itt

Description

This should be used for mgmt tasks like login and nops, or if the LDD's itt space does not include the session age.

The session back_lock must be held.

int **__iscsi_complete_pdu**(struct iscsi_conn * conn, struct iscsi_hdr * hdr, char * data, int datalen)
complete pdu

Parameters

struct iscsi_conn * conn iscsi conn

struct iscsi_hdr * hdr iscsi header

char * data data buffer

int datalen len of data buffer

Description

Completes pdu processing by freeing any resources allocated at queuecommand or send generic. session back_lock must be held and verify itt must have been called.

struct iscsi_task * **iscsi_itt_to_ctask**(struct iscsi_conn * conn, itt_t itt)
look up ctask by itt

Parameters

struct iscsi_conn * conn iscsi connection

itt_t itt itt

Description

This should be used for cmd tasks.

The session back_lock must be held.

void **iscsi_requeue_task**(struct iscsi_task * task)
requeue task to run from session workqueue

Parameters

struct iscsi_task * task task to requeue

Description

LLDs that need to run a task from the session workqueue should call this. The session frwd_lock must be held. This should only be called by software drivers.

void **iscsi_suspend_queue**(struct iscsi_conn * conn)
suspend iscsi_queuecommand

Parameters

struct iscsi_conn * conn iscsi conn to stop queueing IO on

Description

This grabs the session frwd_lock to make sure no one is in xmit_task/queuecommand, and then sets suspend to prevent new commands from being queued. This only needs to be called by offload drivers that need to sync a path like ep disconnect with the iscsi_queuecommand/xmit_task. To start IO again libiscsi will call iscsi_start_tx and iscsi_unblock_session when in FFP.

void **iscsi_suspend_tx**(struct iscsi_conn * conn)
suspend iscsi_data_xmit

Parameters

struct iscsi_conn * conn iscsi conn tp stop processing IO on.

Description

This function sets the suspend bit to prevent iscsi_data_xmit from sending new IO, and if work is queued on the xmit thread it will wait for it to be completed.

int **iscsi_eh_session_reset**(struct scsi_cmnd * sc)
drop session and attempt relogin

Parameters

struct scsi_cmnd * sc scsi command

Description

This function will wait for a relogin, session termination from userspace, or a recovery/replacement timeout.

int **iscsi_eh_recover_target**(struct scsi_cmnd * sc)
reset target and possibly the session

Parameters

struct scsi_cmnd * sc scsi command

Description

This will attempt to send a warm target reset. If that fails, we will escalate to ERL0 session recovery.

int **iscsi_host_add**(struct Scsi_Host * shost, struct device * pdev)
add host to system

Parameters

struct Scsi_Host * shost scsi host

struct device * pdev parent device

Description

This should be called by partial offload and software iscsi drivers to add a host to the system.

struct Scsi_Host * **iscsi_host_alloc**(struct scsi_host_template * sht, int dd_data_size, bool xmit_can_sleep)
allocate a host and driver data

Parameters

struct scsi_host_template * sht scsi host template

int dd_data_size driver host data size

bool xmit_can_sleep bool indicating if LLD will queue IO from a work queue

Description

This should be called by partial offload and software iscsi drivers. To access the driver specific memory use the iscsi_host_priv() macro.

void **iscsi_host_remove**(struct Scsi_Host * shost)
remove host and sessions

Parameters

struct Scsi_Host * shost scsi host

Description

If there are any sessions left, this will initiate the removal and wait for the completion.

struct iscsi_cls_session * **iscsi_session_setup**(struct iscsi_transport * iscsit, struct Scsi_Host * shost, uint16_t cmds_max, int dd_size, int cmd_task_size, uint32_t initial_cmdsn, unsigned int id)
create iscsi cls session and host and session

Parameters

struct iscsi_transport * iscsit iscsi transport template

struct Scsi_Host * shost scsi host

uint16_t cmds_max session can queue

int dd_size private driver data size, added to session allocation size

int cmd_task_size LLD task private data size

uint32_t initial_cmdsn initial CmdSN

unsigned int id target ID to add to this session

Description

This can be used by software iscsi_transports that allocate a session per scsi host.

Callers should set cmds_max to the largest total numer (mgmt + scsi) of tasks they support. The iscsi layer reserves ISCSI_MGMT_CMDS_MAX tasks for nop handling and login/logout requests.

void **iscsi_session_teardown**(struct iscsi_cls_session * cls_session)
destroy session, host, and cls_session

Parameters

struct iscsi_cls_session * cls_session iscsi session

struct iscsi_cls_conn * **iscsi_conn_setup**(struct iscsi_cls_session * cls_session, int dd_size, uint32_t conn_idx)
create iscsi_cls_conn and iscsi_conn

Parameters

struct iscsi_cls_session * cls_session iscsi_cls_session

int dd_size private driver data size

uint32_t conn_idx cid

void **iscsi_conn_teardown**(struct iscsi_cls_conn * cls_conn)
teardown iscsi connection

Parameters

struct iscsi_cls_conn * cls_conn iscsi class connection

Description

TODO: we may need to make this into a two step process like scsi-mls remove + put host

34.6 iSCSI boot information

struct iscsi_boot_kobj * **iscsi_boot_create_target**(struct iscsi_boot_kset * boot_kset, int index, void * data, ssize_t (*show)(void *data, int type, char *buf), umode_t (*is_visible) (void *data, int type), void (*release) (void *data))

create boot target sysfs dir

Parameters

struct iscsi_boot_kset * boot_kset boot kset

int index the target id

void * data driver specific data for target

ssize_t (*) (void *data, int type, char *buf) show attr show function

umode_t (*) (void *data, int type) is_visible attr visibility function

void (*) (void *data) release release function

Note

The boot sysfs lib will free the data passed in for the caller when all refs to the target kobject have been released.

struct iscsi_boot_kobj * **iscsi_boot_create_initiator**(struct iscsi_boot_kset * boot_kset, int index, void * data, ssize_t (*show)(void *data, int type, char *buf), umode_t (*is_visible) (void *data, int type), void (*release) (void *data))

create boot initiator sysfs dir

Parameters

struct iscsi_boot_kset * boot_kset boot kset

int index the initiator id

void * data driver specific data

ssize_t (*) (void *data, int type, char *buf) show attr show function

umode_t (*) (void *data, int type) is_visible attr visibility function

void (*) (void *data) release release function

Note

The boot sysfs lib will free the data passed in for the caller when all refs to the initiator kobject have been released.

struct iscsi_boot_kobj * **iscsi_boot_create_ethernet**(struct iscsi_boot_kset * boot_kset, int index, void * data, ssize_t (*show)(void *data, int type, char *buf), umode_t (*is_visible) (void *data, int type), void (*release) (void *data))

create boot ethernet sysfs dir

Parameters

struct iscsi_boot_kset * boot_kset boot kset

int index the ethernet device id

void * data driver specific data

ssize_t (*) (void *data, int type, char *buf) show attr show function

umode_t (*) (void *data, int type) is_visible attr visibility function

void (*) (void *data) release release function

Note

The boot sysfs lib will free the data passed in for the caller when all refs to the ethernet kobject have been released.

struct iscsi_boot_kobj * **iscsi_boot_create_acpitbl**(struct iscsi_boot_kset * boot_kset, int index, void * data, ssize_t (*show)(void *data, int type, char *buf), umode_t (*is_visible) (void *data, int type), void (*release) (void *data))

create boot acpi table sysfs dir

Parameters

struct iscsi_boot_kset * boot_kset boot kset

int index not used

void * data driver specific data

ssize_t (*)(void *data, int type, char *buf) show attr show function

umode_t (*)(void *data, int type) is_visible attr visibility function

void (*)(void *data) release release function

Note

The boot sysfs lib will free the data passed in for the caller when all refs to the acpitbl kobject have been released.

struct iscsi_boot_kset * **iscsi_boot_create_kset**(const char * set_name)
creates root sysfs tree

Parameters

const char * set_name name of root dir

struct iscsi_boot_kset * **iscsi_boot_create_host_kset**(unsigned int hostno)
creates root sysfs tree for a scsi host

Parameters

unsigned int hostno host number of scsi host

void **iscsi_boot_destroy_kset**(struct iscsi_boot_kset * boot_kset)
destroy kset and kobjects under it

Parameters

struct iscsi_boot_kset * boot_kset boot kset

Description

This will remove the kset and kobjects and attrs under it.

34.7 iSCSI transport class

The file drivers/scsi/scsi_transport_iscsi.c defines transport attributes for the iSCSI class, which sends SCSI packets over TCP/IP connections.

struct iscsi_bus_flash_session * **iscsi_create_flashnode_sess**(struct Scsi_Host * shost, int index, struct iscsi_transport * transport, int dd_size)
Add flashnode session entry in sysfs

Parameters

struct Scsi_Host * shost pointer to host data

int index index of flashnode to add in sysfs

struct iscsi_transport * transport pointer to transport data

int dd_size total size to allocate

Description

Adds a sysfs entry for the flashnode session attributes

Return

pointer to allocated flashnode sess on success NULL on failure

struct iscsi_bus_flash_conn * **iscsi_create_flashnode_conn**(struct Scsi_Host * shost, struct iscsi_bus_flash_session * fnode_sess, struct iscsi_transport * transport, int dd_size)

Add flashnode conn entry in sysfs

Parameters

struct Scsi_Host * shost pointer to host data

struct iscsi_bus_flash_session * fnode_sess pointer to the parent flashnode session entry

struct iscsi_transport * transport pointer to transport data

int dd_size total size to allocate

Description

Adds a sysfs entry for the flashnode connection attributes

Return

pointer to allocated flashnode conn on success NULL on failure

struct device * **iscsi_find_flashnode_sess**(struct Scsi_Host * shost, void * data, int (*fn)(struct device *dev, void *data))

finds flashnode session entry

Parameters

struct Scsi_Host * shost pointer to host data

void * data pointer to data containing value to use for comparison

int (*)(struct device *dev, void *data) fn function pointer that does actual comparison

Description

Finds the flashnode session object comparing the data passed using logic defined in passed function pointer

Return

pointer to found flashnode session device object on success NULL on failure

struct device * **iscsi_find_flashnode_conn**(struct iscsi_bus_flash_session * fnode_sess)
finds flashnode connection entry

Parameters

struct iscsi_bus_flash_session * fnode_sess pointer to parent flashnode session entry

Description

Finds the flashnode connection object comparing the data passed using logic defined in passed function pointer

Return

pointer to found flashnode connection device object on success NULL on failure

void **iscsi_destroy_flashnode_sess**(struct iscsi_bus_flash_session * fnode_sess)
destroy flashnode session entry

Parameters

struct iscsi_bus_flash_session * fnode_sess pointer to flashnode session entry to be destroyed

Description

Deletes the flashnode session entry and all children flashnode connection entries from sysfs

void **iscsi_destroy_all_flashnode**(struct Scsi_Host * shost)
destroy all flashnode session entries

Parameters

struct Scsi_Host * shost pointer to host data

Description

Destroys all the flashnode session entries and all corresponding children flashnode connection entries from sysfs

int **iscsi_scan_finished**(struct Scsi_Host * shost, unsigned long time)
helper to report when running scans are done

Parameters

struct Scsi_Host * shost scsi host

unsigned long time scan run time

Description

This function can be used by drives like qla4xxx to report to the scsi layer when the scans it kicked off at module load time are done.

int **iscsi_block_scsi_eh**(struct scsi_cmnd * cmd)
block scsi eh until session state has transistioned

Parameters

struct scsi_cmnd * cmd scsi cmd passed to scsi eh handler

Description

If the session is down this function will wait for the recovery timer to fire or for the session to be logged back in. If the recovery timer fires then FAST_IO_FAIL is returned. The caller should pass this error value to the scsi eh.

void **iscsi_unblock_session**(struct iscsi_cls_session * session)
set a session as logged in and start IO.

Parameters

struct iscsi_cls_session * session iscsi session

Description

Mark a session as ready to accept IO.

struct iscsi_cls_session * **iscsi_create_session**(struct Scsi_Host * shost, struct iscsi_transport * transport, int dd_size, unsigned int target_id)
create iscsi class session

Parameters

struct Scsi_Host * shost scsi host

struct iscsi_transport * transport iscsi transport

int dd_size private driver data size

unsigned int target_id which target

Description

This can be called from a LLD or iscsi_transport.

struct iscsi_cls_conn * **iscsi_create_conn**(struct iscsi_cls_session * session, int dd_size, uint32_t cid)
create iscsi class connection

Parameters

struct iscsi_cls_session * session iscsi cls session

int dd_size private driver data size

uint32_t cid connection id

Description

This can be called from a LLD or iscsi_transport. The connection is child of the session so cid must be unique for all connections on the session.

Since we do not support MCS, cid will normally be zero. In some cases for software iscsi we could be trying to preallocate a connection struct in which case there could be two connection structs and cid would be non-zero.

int **iscsi_destroy_conn**(struct iscsi_cls_conn * conn)
destroy iscsi class connection

Parameters

struct iscsi_cls_conn * conn iscsi cls session

Description

This can be called from a LLD or iscsi_transport.

int **iscsi_session_event**(struct iscsi_cls_session * session, enum iscsi_uevent_e event)
send session destr. completion event

Parameters

struct iscsi_cls_session * session iscsi class session

enum iscsi_uevent_e event type of event

34.8 iSCSI TCP interfaces

int **iscsi_sw_tcp_recv**(read_descriptor_t * rd_desc, struct sk_buff * skb, unsigned int offset, size_t len)
TCP receive in sendfile fashion

Parameters

read_descriptor_t * rd_desc read descriptor

struct sk_buff * skb socket buffer

unsigned int offset offset in skb

size_t len skb->len - offset

int **iscsi_sw_sk_state_check**(struct sock * sk)
check socket state

Parameters

struct sock * sk socket

Description

If the socket is in CLOSE or CLOSE_WAIT we should not close the connection if there is still some data pending.

Must be called with sk_callback_lock.

void **iscsi_sw_tcp_write_space**(struct sock * sk)
Called when more output buffer space is available

Parameters

struct sock * sk socket space is available for

int **iscsi_sw_tcp_xmit_segment**(struct iscsi_tcp_conn * tcp_conn, struct iscsi_segment * segment)
transmit segment

Parameters

struct iscsi_tcp_conn * tcp_conn the iSCSI TCP connection

struct iscsi_segment * segment the buffer to transmnit

Description

This function transmits as much of the buffer as the network layer will accept, and returns the number of bytes transmitted.

If CRC hashing is enabled, the function will compute the hash as it goes. When the entire segment has been transmitted, it will retrieve the hash value and send it as well.

int **iscsi_sw_tcp_xmit**(struct iscsi_conn * conn)
TCP transmit

Parameters

struct iscsi_conn * conn iscsi connection

int **iscsi_sw_tcp_xmit_qlen**(struct iscsi_conn * conn)
return the number of bytes queued for xmit

Parameters

struct iscsi_conn * conn iscsi connection

int **iscsi_tcp_segment_done**(struct iscsi_tcp_conn * tcp_conn, struct iscsi_segment * segment, int recv, unsigned copied)
check whether the segment is complete

Parameters

struct iscsi_tcp_conn * tcp_conn iscsi tcp connection

struct iscsi_segment * segment iscsi segment to check

int recv set to one of this is called from the recv path

unsigned copied number of bytes copied

Description

Check if we're done receiving this segment. If the receive buffer is full but we expect more data, move on to the next entry in the scatterlist.

If the amount of data we received isn't a multiple of 4, we will transparently receive the pad bytes, too.

This function must be re-entrant.

void **iscsi_tcp_hdr_recv_prep**(struct iscsi_tcp_conn * tcp_conn)
prep segment for hdr reception

Parameters

struct iscsi_tcp_conn * tcp_conn iscsi connection to prep for

Description

This function always passes NULL for the hash argument, because when this function is called we do not yet know the final size of the header and want to delay the digest processing until we know that.

void **iscsi_tcp_cleanup_task**(struct iscsi_task * task)
free tcp_task resources

Parameters

struct iscsi_task * task iscsi task

Description

must be called with session back_lock

int **iscsi_tcp_recv_segment_is_hdr**(struct iscsi_tcp_conn * tcp_conn)
tests if we are reading in a header

Parameters

struct iscsi_tcp_conn * tcp_conn iscsi tcp conn

Description

returns non zero if we are currently processing or setup to process a header.

int **iscsi_tcp_recv_skb**(struct iscsi_conn * conn, struct sk_buff * skb, unsigned int offset, bool offloaded, int * status)
Process skb

Parameters

struct iscsi_conn * conn iscsi connection

struct sk_buff * skb network buffer with header and/or data segment

unsigned int offset offset in skb

bool offloaded bool indicating if transfer was offloaded

int * status iscsi TCP status result

Description

Will return status of transfer in **status**. And will return number of bytes copied.

int **iscsi_tcp_task_init**(struct iscsi_task * task)
Initialize iSCSI SCSI_READ or SCSI_WRITE commands

Parameters

struct iscsi_task * task scsi command task

int **iscsi_tcp_task_xmit**(struct iscsi_task * task)
xmit normal PDU task

Parameters

struct iscsi_task * task iscsi command task

Description

We’re expected to return 0 when everything was transmitted successfully, -EAGAIN if there’s still data in the queue, or != 0 for any other kind of error.

CHAPTER

THIRTYFIVE

MTD NAND DRIVER PROGRAMMING INTERFACE

Author Thomas Gleixner

35.1 Introduction

The generic NAND driver supports almost all NAND and AG-AND based chips and connects them to the Memory Technology Devices (MTD) subsystem of the Linux Kernel.

This documentation is provided for developers who want to implement board drivers or filesystem drivers suitable for NAND devices.

35.2 Known Bugs And Assumptions

None.

35.3 Documentation hints

The function and structure docs are autogenerated. Each function and struct member has a short description which is marked with an [XXX] identifier. The following chapters explain the meaning of those identifiers.

35.3.1 Function identifiers [XXX]

The functions are marked with [XXX] identifiers in the short comment. The identifiers explain the usage and scope of the functions. Following identifiers are used:

- [MTD Interface]

  These functions provide the interface to the MTD kernel API. They are not replaceable and provide functionality which is complete hardware independent.

- [NAND Interface]

  These functions are exported and provide the interface to the NAND kernel API.

- [GENERIC]

  Generic functions are not replaceable and provide functionality which is complete hardware independent.

- [DEFAULT]

  Default functions provide hardware related functionality which is suitable for most of the implementations. These functions can be replaced by the board driver if necessary. Those functions are called via pointers in the NAND chip description structure. The board driver can set the functions which should be replaced by board dependent functions before calling nand_scan(). If the function pointer is NULL on entry to nand_scan() then the pointer is set to the default function which is suitable for the detected chip type.

35.3.2 Struct member identifiers [XXX]

The struct members are marked with [XXX] identifiers in the comment. The identifiers explain the usage and scope of the members. Following identifiers are used:

- [INTERN]

  These members are for NAND driver internal use only and must not be modified. Most of these values are calculated from the chip geometry information which is evaluated during nand_scan().

- [REPLACEABLE]

  Replaceable members hold hardware related functions which can be provided by the board driver. The board driver can set the functions which should be replaced by board dependent functions before calling nand_scan(). If the function pointer is NULL on entry to nand_scan() then the pointer is set to the default function which is suitable for the detected chip type.

- [BOARDSPECIFIC]

  Board specific members hold hardware related information which must be provided by the board driver. The board driver must set the function pointers and datafields before calling nand_scan().

- [OPTIONAL]

  Optional members can hold information relevant for the board driver. The generic NAND driver code does not use this information.

35.4 Basic board driver

For most boards it will be sufficient to provide just the basic functions and fill out some really board dependent members in the nand chip description structure.

35.4.1 Basic defines

At least you have to provide a nand_chip structure and a storage for the ioremap'ed chip address. You can allocate the nand_chip structure using kmalloc or you can allocate it statically. The NAND chip structure embeds an mtd structure which will be registered to the MTD subsystem. You can extract a pointer to the mtd structure from a nand_chip pointer using the nand_to_mtd() helper.

Kmalloc based example

```
static struct mtd_info *board_mtd;
static void __iomem *baseaddr;
```

Static example

```
static struct nand_chip board_chip;
static void __iomem *baseaddr;
```

35.4.2 Partition defines

If you want to divide your device into partitions, then define a partitioning scheme suitable to your board.

```
#define NUM_PARTITIONS 2
static struct mtd_partition partition_info[] = {
    { .name = "Flash partition 1",
      .offset =  0,
      .size =    8 * 1024 * 1024 },
    { .name = "Flash partition 2",
      .offset =  MTDPART_OFS_NEXT,
      .size =    MTDPART_SIZ_FULL },
};
```

35.4.3 Hardware control function

The hardware control function provides access to the control pins of the NAND chip(s). The access can be done by GPIO pins or by address lines. If you use address lines, make sure that the timing requirements are met.

GPIO based example

```
static void board_hwcontrol(struct mtd_info *mtd, int cmd)
{
    switch(cmd){
        case NAND_CTL_SETCLE: /* Set CLE pin high */ break;
        case NAND_CTL_CLRCLE: /* Set CLE pin low */ break;
        case NAND_CTL_SETALE: /* Set ALE pin high */ break;
        case NAND_CTL_CLRALE: /* Set ALE pin low */ break;
        case NAND_CTL_SETNCE: /* Set nCE pin low */ break;
        case NAND_CTL_CLRNCE: /* Set nCE pin high */ break;
    }
}
```

Address lines based example. It' s assumed that the nCE pin is driven by a chip select decoder.

```
static void board_hwcontrol(struct mtd_info *mtd, int cmd)
{
    struct nand_chip *this = mtd_to_nand(mtd);
    switch(cmd){
        case NAND_CTL_SETCLE: this->legacy.IO_ADDR_W |= CLE_ADRR_BIT; ␣
↪break;
        case NAND_CTL_CLRCLE: this->legacy.IO_ADDR_W &= ~CLE_ADRR_BIT;␣
↪break;
        case NAND_CTL_SETALE: this->legacy.IO_ADDR_W |= ALE_ADRR_BIT; ␣
↪break;
        case NAND_CTL_CLRALE: this->legacy.IO_ADDR_W &= ~ALE_ADRR_BIT;␣
↪break;
    }
}
```

35.4.4 Device ready function

If the hardware interface has the ready busy pin of the NAND chip connected to a GPIO or other accessible I/O pin, this function is used to read back the state of the pin. The function has no arguments and should return 0, if the device is busy (R/B pin is low) and 1, if the device is ready (R/B pin is high). If the hardware interface does not give access to the ready busy pin, then the function must not be defined and the function pointer this->legacy.dev_ready is set to NULL.

35.4.5 Init function

The init function allocates memory and sets up all the board specific parameters and function pointers. When everything is set up nand_scan() is called. This function tries to detect and identify then chip. If a chip is found all the internal data fields are initialized accordingly. The structure(s) have to be zeroed out first and then filled with the necessary information about the device.

```
static int __init board_init (void)
{
    struct nand_chip *this;
    int err = 0;

    /* Allocate memory for MTD device structure and private data */
    this = kzalloc(sizeof(struct nand_chip), GFP_KERNEL);
    if (!this) {
        printk ("Unable to allocate NAND MTD device structure.\n");
        err = -ENOMEM;
        goto out;
    }

    board_mtd = nand_to_mtd(this);

    /* map physical address */
    baseaddr = ioremap(CHIP_PHYSICAL_ADDRESS, 1024);
    if (!baseaddr) {
```

(continues on next page)

(continued from previous page)

```
        printk("Ioremap to access NAND chip failed\n");
        err = -EIO;
        goto out_mtd;
    }

    /* Set address of NAND IO lines */
    this->legacy.IO_ADDR_R = baseaddr;
    this->legacy.IO_ADDR_W = baseaddr;
    /* Reference hardware control function */
    this->hwcontrol = board_hwcontrol;
    /* Set command delay time, see datasheet for correct value */
    this->legacy.chip_delay = CHIP_DEPENDEND_COMMAND_DELAY;
    /* Assign the device ready function, if available */
    this->legacy.dev_ready = board_dev_ready;
    this->eccmode = NAND_ECC_SOFT;

    /* Scan to find existence of the device */
    if (nand_scan (this, 1)) {
        err = -ENXIO;
        goto out_ior;
    }

    add_mtd_partitions(board_mtd, partition_info, NUM_PARTITIONS);
    goto out;

out_ior:
    iounmap(baseaddr);
out_mtd:
    kfree (this);
out:
    return err;
}
module_init(board_init);
```

35.4.6 Exit function

The exit function is only necessary if the driver is compiled as a module. It releases all resources which are held by the chip driver and unregisters the partitions in the MTD layer.

```
#ifdef MODULE
static void __exit board_cleanup (void)
{
    /* Unregister device */
    WARN_ON(mtd_device_unregister(board_mtd));
    /* Release resources */
    nand_cleanup(mtd_to_nand(board_mtd));

    /* unmap physical address */
    iounmap(baseaddr);

    /* Free the MTD device structure */
    kfree (mtd_to_nand(board_mtd));
}
```

(continues on next page)

(continued from previous page)

```
module_exit(board_cleanup);
#endif
```

35.5 Advanced board driver functions

This chapter describes the advanced functionality of the NAND driver. For a list of functions which can be overridden by the board driver see the documentation of the nand_chip structure.

35.5.1 Multiple chip control

The nand driver can control chip arrays. Therefore the board driver must provide an own select_chip function. This function must (de)select the requested chip. The function pointer in the nand_chip structure must be set before calling nand_scan(). The maxchip parameter of nand_scan() defines the maximum number of chips to scan for. Make sure that the select_chip function can handle the requested number of chips.

The nand driver concatenates the chips to one virtual chip and provides this virtual chip to the MTD layer.

Note: The driver can only handle linear chip arrays of equally sized chips. There is no support for parallel arrays which extend the buswidth.

GPIO based example

```
static void board_select_chip (struct mtd_info *mtd, int chip)
{
    /* Deselect all chips, set all nCE pins high */
    GPIO(BOARD_NAND_NCE) |= 0xff;
    if (chip >= 0)
        GPIO(BOARD_NAND_NCE) &= ~ (1 << chip);
}
```

Address lines based example. Its assumed that the nCE pins are connected to an address decoder.

```
static void board_select_chip (struct mtd_info *mtd, int chip)
{
    struct nand_chip *this = mtd_to_nand(mtd);

    /* Deselect all chips */
    this->legacy.IO_ADDR_R &= ~BOARD_NAND_ADDR_MASK;
    this->legacy.IO_ADDR_W &= ~BOARD_NAND_ADDR_MASK;
    switch (chip) {
    case 0:
